The Witten Index for One-dimensional Non-unitary Quantum Walks with Gapless Time-evolution

Keisuke Asahara · Daiju Funakawa · Motoki Seki · Yohei Tanaka

Abstract Recent developments in the index theory of discrete-time quantum walks allow us to assign a certain well-defined supersymmetric index to a pair of a unitary time-evolution \( U \) and a \( \mathbb{Z}_2 \)-grading operator \( T \) satisfying the chiral symmetry condition \( U^* = T U T \). In this paper, this index theory will be extended to encompass non-unitary \( U \). The existing literature for unitary \( U \) makes use of the indispensable assumption that \( U \) is essentially gapped; that is, we require that the essential spectrum of \( U \) contains neither \(-1\) nor \(+1\) to define the associated index. It turns out that this assumption is no longer necessary, if the given time-evolution \( U \) is non-unitary. As a concrete example, we shall consider a well-known non-unitary quantum walk model on the one-dimensional integer lattice, introduced by Mochizuki-Kim-Obuse.

Keywords Chiral symmetry, Non-unitary quantum walks, Supersymmetry, Witten index, Split-step quantum walks

1 Introduction

The theory of (discrete-time) quantum walks has attracted enormous attention over the past few decades. Despite its apparent simplicity, vast applications of this ubiquitous no-
tion can be found across multiple disciplines. For instance, the physical utility of quantum walks is especially confirmed for quantum algorithms [Gro96, ABN’01], photosynthesis [MRLAG08, PLM’10], and topological insulators [KRBD10, OK11, Kit12a, A013].

The long-time limit of the velocity distribution of the quantum walker, known as the weak limit theorem [Kon02, GJS04, Suz16], has been a particularly active theme of mathematical studies. Various long-time behaviors have been studied, and a general linear analysis [MSS18, Seg11, CGML12, FFS17, FFS18], quantum walks on graphs [AAKV01, Amb03, Por16], non-linear analysis [MSS18b, MSS18a, MSS19], unitary equivalence classes [Ohn16, Ohn17, Ohn18, KNO20], time operators [ST19a, FMS20], and continuous limit [MS19].

The present article is a continuation of rigorous mathematical studies of index theory for chirally symmetric quantum walks from the perspective of supersymmetric quantum mechanics [CGS16, CGG18, CGG18, Suz19, ST19a, Mat20, CGWW20]. Such a quantum walk can be naturally identified with a pair of a time-evolution operator $U : \mathcal{H} \to \mathcal{H}$ and a unitary self-adjoint operator $\Gamma : \mathcal{H} \to \mathcal{H}$, satisfying the chiral symmetry condition:

$$U^* = \Gamma U$$

where $\Gamma$ gives a $\mathbb{Z}_2$-grading of the underlying state Hilbert space $\mathcal{H} = \ker(\Gamma - 1) \oplus \ker(\Gamma + 1)$.

The existing literature mentioned above allows us to assign a certain well-defined Fredholm index, denoted by $\text{ind}(\Gamma, U)$, to each abstract chirally symmetric quantum walk $(\Gamma, U)$. Note that this assignment of the Fredholm index requires $U$ to be both essentially unitary (i.e. $U$ is a unitary element in the Calkin $C^*$-algebra) and essentially gapped (i.e. the essential spectrum of $U$, denoted by $\sigma_{\text{ess}}(U)$, contains neither $-1$ nor $+1$).

The present article extends this index theory to encompass all those time-evolutions $U$ which fail to be essentially unitary. As a concrete example, we shall explicitly construct such a time-evolution $U$ with the property that it is essentially gapless, yet the associated index is well-defined. To put this into context, let us consider the following time-evolution operator on the state Hilbert space $\mathcal{H} := l^2(\mathbb{Z}, \mathbb{C}^2)$ of square-summable $\mathbb{C}^2$-valued sequences:

$$U_{\text{mko}} := SG\Phi C_2 SG^{-1}\Phi C_1,$$

where the operators $S, G, \Phi, C_1, C_2$ are defined respectively as the following block-operator matrices with respect to the orthogonal decomposition $\mathcal{H} = l^2(\mathbb{Z}, \mathbb{C}) \oplus l^2(\mathbb{Z}, \mathbb{C})$:

$$S := \begin{pmatrix} L & 0 \\ 0 & L^{-1} \end{pmatrix}, \quad G := \begin{pmatrix} e^\gamma & 0 \\ 0 & e^{-\gamma(i+1)} \end{pmatrix}, \quad \Phi := \begin{pmatrix} e^{i\phi} & 0 \\ 0 & e^{-i\phi(i+1)} \end{pmatrix}, \quad C_j := \begin{pmatrix} \cos \theta_j & i \sin \theta_j \\ i \sin \theta_j & \cos \theta_j \end{pmatrix},$$

where $L$ is the unitary unilateral left-shift operator defined by $L\Psi := \Psi(-1)$ for each $\Psi \in l^2(\mathbb{Z}, \mathbb{C})$, and where we assume that four $\mathbb{R}$-valued sequences $\gamma = (\gamma(x))_{x \in \mathbb{Z}}, \phi = (\phi(x))_{x \in \mathbb{Z}}, \theta_1 = (\theta_1(x))_{x \in \mathbb{Z}}, \theta_2 = (\theta_2(x))_{x \in \mathbb{Z}}$, all of which are identified with the corresponding multiplication operators on $l^2(\mathbb{Z}, \mathbb{C})$, admit the following two-sided limits:

$$\xi(\ast) := \lim_{x \to \ast} \xi(x) \in \mathbb{R}, \quad \xi \in \{\gamma, \phi, \theta_1, \theta_2\}, \quad \ast = \pm \infty.$$

This model is a natural generalisation of the homogenous model considered in [MKO16, §III.A] with the time-evolution (2) being consistent with the experimental setup in [RBM12] (see [MKO16, §I-II] for details). Note that $U_{\text{mko}}$ is non-unitary, unless $\gamma$ is identically zero.

We shall explicitly construct a $\mathbb{Z}_2$-grading operator $I_{\text{mko}} : \mathcal{H} \to \mathcal{H}$ in a highly non-trivial fashion, so that $(I_{\text{mko}}, U_{\text{mko}})$ forms a chirally symmetric quantum walk. Complete classification of the two topological invariants $\text{ind}(I_{\text{mko}}, U_{\text{mko}})$ and $\sigma_{\text{ess}}(U_{\text{mko}})$ can be found...
in this paper. In particular, we show that $\sigma_{\text{ess}}(U_{m\text{mko}})$ is a subset of the union of the unit circle $\mathbb{T}$ and the real line $\mathbb{R}$, given explicitly by the following formula:

$$\sigma_{\text{ess}}(U_{m\text{mko}}) = \sigma(-\infty) \cup \sigma(+\infty),$$

where the sets $\sigma(\pm\infty) \subseteq \mathbb{T} \cup \mathbb{R}$ depend only on the two asymptotic values $\theta_1(\pm\infty), \theta_2(\pm\infty)$.

As in Fig. 1, it is shown in this paper that for each $\star=\pm\infty$, there exists a well-defined subinterval $[\gamma_-(\star), \gamma_+(\star)]$ of $[0, \infty]$, which enables us to classify $\sigma(\star)$ into 6 different cases in total, depending on the sign $s(\star)$ of $-\sin \theta_1(\star) \sin \theta_2(\star)$.

**Fig. 1** The set $\sigma(\star) \subseteq \mathbb{T} \cup \mathbb{R}$ is classified into Cases I, II, III as above according to the size of $|\gamma(\star)|$. If $s(\star) = 1$ (resp. if $s(\star) = -1$), then the black regions (resp. gray regions) in each of the above three cases depict the subset $\sigma(\star)$. Therefore, there are 6 distinct cases in total. In particular, $\sigma(\star)$ is a connected subset of $\mathbb{T} \cup \mathbb{R}$ containing either $-1$ or $+1$, and so Case II is of significant importance.

The present article is organised as follows. §2.1 is a preliminary. In §2.2 we state the main theorems of this paper, proofs of which will be completely deferred to §3. In particular, it is shown in Theorem [B] that the 2-step chirally symmetric quantum walk $(I_{m\text{mko}}, U_{m\text{mko}})$ can be naturally generalised to another $m$-step chirally symmetric quantum walk, denoted by $(I_m, U_m)$ in this paper, where $m$ can be any fixed non-zero integer. This new model also unifies the one-dimensional unitary quantum walks in [ABN+01, Kon02, Suz16, KRBD10, KBF+12, Kit12b, FFS17, FFS18, FFS19, ST19b, Mat20, Tan20]. Complete classification of the two topological invariants $\text{ind}(I_m, U_m)$ and $\sigma_{\text{ess}}(U_m)$ can be collectively found in Theorem [C]. With the aid of Theorems [B] to [C] we show in §2.5 that the non-unitary time-evolution $U_{m\text{mko}}$ can have a well-defined index, yet it is essentially gapless (see Example [D] for details). This construction is based upon Case II in Fig. 1. In §3 we prove the main theorems in §2. In particular, we shall make use of an abstract form of the one-dimensional bulk-boundary correspondence to fully classify $\text{ind}(I_m, U_m)$. The paper concludes with the summary and discussion in §4.

2 Main theorems and discussion

Proofs of the main theorems of the current section can be collectively found in §3.
2.1 Preliminaries

By operators we shall always mean everywhere-defined bounded operators between Hilbert spaces throughout this paper. An operator $X$ is said to be Fredholm, if $\ker X, \ker X^*$ are finite-dimensional and if $X$ has a closed range. If $X$ is Fredholm, then the Fredholm index of $X$ is defined by

$$\text{ind } X := \dim \ker X - \dim \ker X^*.$$  

If the domain and range of $X$ are identical, then the (Fredholm) essential spectrum of $X$ is defined by $\sigma_{\text{ess}}(X) := \{ z \in \mathbb{C} \mid X - z \text{ is not Fredholm} \}$. In particular, we call $X$ essentially gapped, if $-1, +1 \notin \sigma_{\text{ess}}(X)$ following [CGG18, CGS18].

A chiral pair on $\mathcal{H}$ is any pair $(\Gamma, U)$ of a unitary self-adjoint operator $\Gamma$ on $\mathcal{H}$ and an operator $U$ on $\mathcal{H}$ satisfying the chiral symmetry condition (1). Note that $\Gamma$ gives a $\mathbb{Z}_2$-grading of the underlying Hilbert space $\mathcal{H} = \ker(\Gamma - 1) \oplus \ker(\Gamma + 1)$, and that $\Gamma = 1 \oplus (-1)$ with respect to this orthogonal decomposition, where 1 denotes the identity operator on a Hilbert space throughout this paper. The operator $U$ can be written as $U = R + iQ$, where $R, Q$ are the real and imaginary parts of $U$ respectively. More precisely, $R, Q$ admit the following block-operator matrix representations:

$$R = \begin{pmatrix} R_1 & 0 \\ 0 & R_2 \end{pmatrix}_{\ker(\Gamma - 1) \oplus \ker(\Gamma + 1)}, \quad Q = \begin{pmatrix} 0 & Q^*_1 \\ Q_0 & 0 \end{pmatrix}_{\ker(\Gamma - 1) \oplus \ker(\Gamma + 1)},$$

where the first equality (resp. second equality) follows from $[\Gamma, R] := \Gamma R - R \Gamma = 0$ (resp. from $[\Gamma, Q] := \Gamma Q + Q \Gamma = 0$).

**Definition 1.** Let $(\Gamma, U)$ be a chiral pair on a Hilbert space $\mathcal{H}$, and let $Q$ be the imaginary part of $U$ given by the second equality in (4). Then the chiral pair $(\Gamma, U)$ is said to be Fredholm, if $0 \notin \sigma_{\text{ess}}(Q)$ (or, equivalently, $Q_0$ is Fredholm). In this case, the Witten index of the Fredholm chiral pair $(\Gamma, U)$ is defined by $\text{ind } (\Gamma, U) := \text{ind } Q_0$.

We shall make use of the following unitary invariance property of the Witten index throughout this paper;

**Lemma 2 (unitary invariance).** Let $(\Gamma', U'), (\Gamma'', U'')$ be two chiral pairs on two Hilbert spaces $\mathcal{H}, \mathcal{H}'$ respectively. If $(\Gamma', U'), (\Gamma'', U'')$ are unitarily equivalent in the sense that $(\Gamma', U') = (e^{i\epsilon} \Gamma', e^{i\epsilon} U')$ for some unitary operator $e : \mathcal{H}' \rightarrow \mathcal{H}$, then $(\Gamma', U')$ is Fredholm if and only if so is $(\Gamma'', U'')$. In this case, we have $\text{ind } (\Gamma', U') = \text{ind } (\Gamma'', U'')$.

2.2 Main theorems

We are now in position to introduce the main model of the present article;

**Definition A.** Let $m$ be a fixed non-zero integer, and let $(\Gamma_m, U_m)$ be the pair of the following block-operator matrices with respect to $L^2(\mathbb{Z}, \mathbb{C}^2) = L^2(\mathbb{Z}) \oplus L^2(\mathbb{Z})$:

$$\Gamma_m := \begin{pmatrix} p & qL_m^m \\ L^{-m}q^* & -p(-m) \end{pmatrix}, \quad U_m := \begin{pmatrix} p & qL_m^m \\ L^{-m}q^* & -p(-m) \end{pmatrix} \left( \begin{array}{cc} e^{-2\gamma (\gamma + 1)}a & e^{\gamma - \gamma (\gamma + 1)b} \\ e^{\gamma - \gamma (\gamma + 1)b} & -e^{2\gamma}a \end{array} \right).$$
where we assume that three convergent $\mathbb{R}$-valued sequences $\gamma = (\gamma(x))_{x \in \mathbb{Z}}, p = (p(x))_{x \in \mathbb{Z}}, a = (a(x))_{x \in \mathbb{Z}}$ and two convergent $\mathbb{C}$-valued sequences $q = (q(x))_{x \in \mathbb{Z}}, b = (b(x))_{x \in \mathbb{Z}}$ satisfy the following conditions:

\[ p(x)^2 + |q(x)|^2 = 1, \quad x \in \mathbb{Z}, \quad (A3) \]
\[ a(x)^2 + |b(x)|^2 = 1, \quad x \in \mathbb{Z}, \quad (A4) \]
\[ \xi(\pm \infty) := \lim_{x \to \pm \infty} \xi(x), \quad \xi \in \{ \gamma, p, a, q, b \}, \quad (A5) \]
\[ \theta(\pm \infty) := \begin{cases} \arg q(\pm \infty), & q(\pm \infty) \neq 0, \\ 0, & q(\pm \infty) = 0, \end{cases} \quad \theta'(\pm \infty) := \begin{cases} \arg b(\pm \infty), & b(\pm \infty) \neq 0, \\ 0, & b(\pm \infty) = 0, \end{cases} \quad (A6) \]

where $\arg w$ of a non-zero complex number $w$ is uniquely defined by $w = e^{i \arg w}$ and $\arg w \in [0, 2\pi)$.

The pair $(\Gamma_m, U_m)$ introduced in Definition\[\text{[A]}\] where $\Gamma_m$ is unitary self-adjoint by $(A3)$, turns out to be a chiral pair. Indeed, $U_m$ can be uniquely written as $U_m = \Gamma_m C$, where $C$ is self-adjoint, and so

\[ U_m^* = (\Gamma_m C)^* = C^* \Gamma_m^* = C \Gamma_m = \Gamma_m^2 C \Gamma_m = \Gamma_m U_m \Gamma_m, \]

where the second last equality follows from $\Gamma_m^2 = 1$. The chiral pair $(\Gamma_m, U_m)$ unifies all of the following existing models on the one-dimensional integer lattice $\mathbb{Z}$:

- If $m = 1$ and if $\gamma$ is identically 0, then $U_1$ is the unitary evolution of a split-step quantum walk model considered in [KRB_D10, KPB_T12, Knt12b, FPS17, FPS18, FPS19, ST19b, Mnt20, Fnt20]. In particular, if we set $p = 0$, then this model becomes the usual one-dimensional quantum walk model considered in [ABN01, Kon02, Suz16].
- If $m = 2$, then $U_2$ turns out to be equivalent to the non-unitary evolution operator $U_{\text{mko}}$ given by 2 in sense of the following theorem.

**Theorem B.** Let $U_{\text{mko}}$ be given by 2, where we assume that four convergent $\mathbb{R}$-valued sequences $\gamma, \phi, \theta_1, \theta_2$ admit the two-sided limits of the form 4. Then there exists a unitary self-adjoint operator $U_{\text{mko}}$ on $L^2(\mathbb{Z}, \mathbb{C}^2)$, such that $(\Gamma_m, U_{\text{mko}})$ forms a chiral pair. Moreover, the chiral pair $(\Gamma_m, U_{\text{mko}})$ is unitarily equivalent to the chiral pair $(\Gamma_2, U_2)$, where the sequences $p, q, a, b$ are defined respectively by

\[ p := -\sin \theta_1 (\cdot + 1), \quad q := -i \cos \theta_1 (\cdot + 1), \quad a := \sin \theta_2, \quad b := i \cos \theta_2 e^{i(\phi + \phi(\cdot + 1))}. \quad (B1) \]

Complete classification of the two topological invariants $\text{ind} (\Gamma_m, U_m)$ and $\sigma_{\text{ess}}(U_m)$ can be collectively found in the following theorem.

**Theorem C.** If $(\Gamma_m, U_m)$ is the chiral pair in Definition\[\text{[A]}\] then we have the following two assertions:

(i) **Classification of the Witten index.** For each $\star = \pm \infty$, we let

\[ p_\star(\star) := \frac{p(\star)}{\sqrt{p(\star)^2 + |q(\star)|^2 \cosh^2(2\gamma(\star))}}, \quad (C1) \]
Then the chiral pair \((T_m, U_m)\) is Fredholm if and only if \(|p_\gamma(\star)| \neq |a(\star)|\) for each \(\star = \pm \infty\). In this case, we have the following index formula:

\[
\text{ind}(T_m, U_m) = \begin{cases} 
0, & |p_\gamma(-\infty)| < |a(-\infty)|, |p_\gamma(+\infty)| < |a(+\infty)|, \\
\text{sgn}(p(+\infty)), & |p_\gamma(-\infty)| < |a(-\infty)|, |p_\gamma(+\infty)| > |a(+\infty)|, \\
-\text{sgn}(p(-\infty)), & |p_\gamma(-\infty)| > |a(-\infty)|, |p_\gamma(+\infty)| < |a(+\infty)|, \\
\text{sgn}(p(+\infty)) - \text{sgn}(p(-\infty)), & |p_\gamma(-\infty)| > |a(-\infty)|, |p_\gamma(+\infty)| > |a(+\infty)|, 
\end{cases}
\]

where the sign function \(\text{sgn} : \mathbb{R} \rightarrow \{-1, 1\}\) is defined by

\[
\text{sgn} x := \begin{cases} 
\frac{x}{|x|}, & x \neq 0, \\
1, & x = 0.
\end{cases}
\]

(ii) **Classification of the essential spectrum.** For each \(\star = \pm \infty\), we let

\[
s(\star) := \text{sgn}(p(\star)a(\star)),
\]

\[
\Lambda_{\pm}(\star) := |p(\star)a(\star)| \cosh(2\gamma(\star)) \pm |q(\star)b(\star)|,
\]

\[
\sigma(\star) := \bigcup_{n \in \{-1, +1\}} \left\{ x + \sqrt{x^2 - 1} \right\} s(\star)x \in [\Lambda_-(\star), \Lambda_+(\star)].
\]

Then the essential spectrum of \(U_m\) can be written as \(\sigma_{\text{ess}}(U_m) = \sigma(-\infty) \cup \sigma(+\infty)\). Furthermore, for each \(\star = \pm \infty\) there exists a well-defined closed interval \([\gamma_-(\star), \gamma_+(\star)]\) \(\subseteq [0, \infty]\), such that the set \(\sigma(\star)\) admits the following further classification:

- **Case I.** If \(|\gamma(\star)| \leq \gamma_-(\star)\), then \([\Lambda_-(\star), \Lambda_+(\star)] \subseteq [-1, 1]\), and so \(\sigma(\star) \subseteq T\).
- **Case II.** If \(\gamma_-(\star) < |\gamma(\star)| < \gamma_+(\star)\), then \([\Lambda_-(\star), 1] \subseteq [-1, 1]\) and \([1, \Lambda_+(\star)] \subseteq [1, \infty]\), and so \(\sigma(\star)\) is a connected subset of \(T \cup \mathbb{R}\) containing \(s(\star)\).
- **Case III.** If \(\gamma_+(\star) \leq |\gamma(\star)|\), then \([\Lambda_-(\star), \Lambda_+(\star)] \subseteq [1, \infty]\), and so \(\sigma(\star) \subseteq \mathbb{R}\).

More explicitly, for each \(\star = \pm \infty\) the closed interval \([\gamma_-(\star), \gamma_+(\star)]\) is given by

\[
\gamma_{\pm}(\star) := \frac{1}{2} \cosh^{-1}\left( 1 \pm \frac{|q(\star)b(\star)|}{|p(\star)a(\star)|} \right),
\]

where \(\cosh^{-1}\) denotes the inverse function of \([0, \infty] \ni x \mapsto \cosh x \in [1, \infty]\) with \(1/0 := \infty\) by convention.

Explicit formulas for \(\sigma(\star) \subseteq T \cup \mathbb{R}\) in Cases I, II, III of Theorem C (ii) will be given shortly in \(\ref{thm:classification}\). This will allow us to classify \(\sigma(\star)\) into the 6 different cases as in Fig. \(\ref{fig:classification}\).

**Remark 3.** If \(\gamma\) is identically zero and if \(m = 1\), then \(U_1\) is the unitary time-evolution of a split-step quantum walk, and the formula for \(\text{ind}(T_1, U_1)\) can be found in \([\text{ST19b}, \text{Mat20}, \text{Tan20}])\). Similarly, under the same assumption, Theorem C (ii) coincides with \([\text{ST19b}, \text{Theorem 30}]\) or \([\text{Tan20}\text{, Theorem B (ii)}]\).

2.3 Discussion

Let us start with the following lemma;
Lemma 4. Let \((\Gamma, U)\) be an abstract chiral pair on a Hilbert space \(H\), and let \(Q\) be the imaginary part of \(U\). If \(U\) is essentially unitary (i.e. \(U^*U = 1, UU^* = 1\) are compact), then
\[
\sigma_{\text{ess}}(Q) = \left\{ \frac{z - z^*}{2i} \mid z \in \sigma_{\text{ess}}(U) \right\}.
\] (5)
That is, if \(U\) is essentially unitary, then the chiral pair \((\Gamma, U)\) is Fredholm if and only if \(U\) is essentially gapped in the sense of \(\S 2.1\).

Proof. The formula (5) can be easily proved by using the spectral mapping theorem and the trigonometric polynomial \(p(z) := (z - z^*)/(2i)\). We omit the proof, since an analogous argument can be found in \cite{Tan20} Lemma 3.6. □

As in the following theorem, given an abstract chiral pair \((\Gamma, U)\), where \(U\) may not necessarily be essentially unitary, the essential gappedness of \(U\) is no longer an indispensable assumption to ensure the Fredholmness of the chiral pair \((\Gamma, U)\);

Theorem 5. With the notation introduced in Theorem \(\Psi\) suppose that the following hold true for each \(\star = \pm \infty\) :
\[
|p_\gamma(\star)| \neq |a(\star)|, \quad \gamma_-(\star) < |\gamma(\star)| < \gamma_+(\star).
\] (6)
Then \((\Gamma_m, U_m)\) is Fredholm, yet \(U_m\) fails to be essentially gapped.

Proof. Let us first start with further classification of \(\sigma_{\text{ess}}(U)\) given by Theorem \(\Psi\)(ii). We consider the following \(\mathbb{R}\)-valued function \(g\) defined on \((-\infty, -1] \cup [1, \infty)\):
\[
g(x) := x + \sqrt{x^2 - 1}, \quad x \in (-\infty, -1] \cup [1, \infty).
\]
Fig. 2 shows the graphs of \(g, 1/g\):

![Graph of g and 1/g](image)

Fig. 2 The black graph corresponds to \(g\), and the gray graph corresponds to \(g^{-1}\).

Evidently, \(g(x)g(-x)^{-1} = -1\) for \(|x| \geq 1\). It follows that for each \(\star = \pm \infty\) the set \(\sigma(\star)\) admits the following further classification:

\[
\sigma_{\text{ess}}(U) = \left\{ \frac{z - z^*}{2i} \mid z \in \sigma_{\text{ess}}(U) \right\}.
\]
• Case I. If \( |\gamma(*)| \leq \gamma_-(*) \), then
\[
\sigma(*) = \begin{cases} 
[z \in \mathbb{T} | \text{Re } z \in [\Lambda_-(*) , \Lambda_+(*)]], & s(*) = 1, \\
[z \in \mathbb{T} | \text{Re } z \in [-\Lambda_+(*) , -\Lambda_-(*)]], & s(*) = -1.
\end{cases}
\]

• Case II. If \( \gamma_-(*) < |\gamma(*)| < \gamma_+(*) \), then
\[
\sigma(*) = \begin{cases} 
[z \in \mathbb{T} | \text{Re } z \in [\Lambda_-(*) , 1]], & g(\Lambda_+(*)^{-1}, g(\Lambda_+(*)), s(*) = 1, \\
[z \in \mathbb{T} | \text{Re } z \in [-1 , -\Lambda_-(*)]], & -g(\Lambda_+(*)^{-1}, -g(\Lambda_+(*)], s(*) = -1.
\end{cases}
\]

• Case III. If \( \gamma_+(*) \leq |\gamma(*)| \), then
\[
\sigma(*) = \begin{cases} 
[g(\Lambda_+(*)^{-1}, g(\Lambda_-(*)^{-1}) \cup [g(\Lambda_-(*)], g(\Lambda_+(*)], s(*) = 1, \\
[-g(\Lambda_+(*)^{-1}, -g(\Lambda_+(*)] \cup [-g(\Lambda_-(*)^{-1}, -g(\Lambda_+(*)], s(*) = -1.
\end{cases}
\]

That is, \( \sigma(*) \) is classified into the 6 different cases as in Fig. 1. It immediately follows from Theorem C and E that \( (\mathcal{I}_m, \mathcal{U}_m) \) is Fredholm, and that \( \mathcal{E}(\mathcal{U}_m) = \sigma(-\infty) \cup \sigma(+\infty) \). In particular, for each \( \star = \pm \infty \) the set \( \sigma(*) \) is classified as Case II. That is, each \( \sigma(*) \) is a connected subset of \( \mathbb{T} \cup \mathbb{R} \) containing either \(-1\) or \(+1\), and so \( \mathcal{U}_m \) fails to be essentially gapped. The claim follows. \( \square \)

The current section concludes with the following two numerical examples:

Example 6. Let \( (\mathcal{I}_m, \mathcal{U}_m) \) be the chiral pair in Theorem C. Let
\[
p_0 := 0.2, \quad a_0 := 0.1, \quad \gamma_0 := 0.4.
\]
If \( a(\pm \infty) := \pm a_0 \) and \( p(\pm \infty) := \pm p_0 \), then (C7) becomes
\[
\gamma_-(\pm \infty) = \gamma_+(\pm \infty) = \frac{1}{2} \cosh^{-1}\left( \frac{1 - \sqrt{1 - p_0^2} \sqrt{1 - a_0^2}}{|p_0 a_0|} \right) = 0.350396,
\]
\[
\gamma_+(\pm \infty) = \gamma_+(\pm \infty) = \frac{1}{2} \cosh^{-1}\left( \frac{1 + \sqrt{1 - p_0^2} \sqrt{1 - a_0^2}}{|p_0 a_0|} \right) = 2.64283.
\]

If we let \( \gamma(\pm \infty) := \gamma_0 \), then \( \gamma_-(\pm \infty) < |\gamma_0| < \gamma_+(\pm \infty) \). It follows from (C6) that \( \mathcal{E}(\mathcal{U}_m) = \sigma(-\infty) = \sigma(+\infty) \), since \( s(-\infty) = s(+\infty) = 1 \). More precisely, the set \( \mathcal{E}(\mathcal{U}_m) = \sigma(\pm \infty) \) is classified as Case II:
\[
\Lambda_{\pm} := |p_0 a_0| \cosh(2\gamma_0) \pm \sqrt{1 - p_0^2} \sqrt{1 - a_0^2},
\]
\[
\mathcal{E}(\mathcal{U}_m) := \{ z \in \mathbb{T} | \text{Re } z \in [\Lambda_{-1}], \cup [g(\Lambda_+(*)^{-1}, g(\Lambda_+(*)],
\]

The black region in Cases II of Fig. 1 depicts the connected subset \( \mathcal{E}(\mathcal{U}_m) \) of \( \mathbb{T} \cup \mathbb{R} \) containing \( \Lambda_{-1} \). It follows that \( \mathcal{U}_m \) is not essentially gapped. Furthermore, (C4) becomes
\[
|p_{\gamma}(\pm \infty)| = \frac{|p_0|}{\sqrt{p_0^2 + (1 - p_0) \cosh^2(2\gamma_0)}} = 0.150876 > |\alpha(\pm \infty)| = 0.1.
\]

It follows that \( (\mathcal{I}_m, \mathcal{U}_m) \) is Fredholm, and \( \text{ind}(\mathcal{I}_m, \mathcal{U}_m) = m(+1 - (-1)) = 2m \) by the index formula (C2). That is, we have constructed the Fredholm chiral pair \( (\mathcal{I}_m, \mathcal{U}_m) \), in such a way that \( \mathcal{U}_m \) fails to be essentially gapped, yet \( \text{ind}(\mathcal{I}_m, \mathcal{U}_m) = 2m \) is well-defined.
Example 7. Let $U_{mko}$ be the non-unitary evolution operator given by (2), where we assume the existence of the two-sided limits (3). We define $p, q, a, b$ according to [B1], and Theorem [B] asserts $\Gamma_{mko}, U_{mko}) \approx (I_2, U_2)$, where $\approx$ denotes unitary equivalence of chiral pairs. As in Example [B] we choose $\theta_1(\pm \infty), \theta_2(\pm \infty), \gamma(\pm \infty)$ in such a way that

$$p(\pm \infty) = \pm 0.2, \quad a(\pm \infty) = \pm 0.1, \quad \gamma(\pm \infty) = 0.4.$$ 

It follows that $(\Gamma_{mko}, U_{mko}) \approx (I_2, U_2)$ is Fredholm, and $\text{ind} (\Gamma_{mko}, U_{mko}) = 4$. Furthermore, $U_{mko}$ is essentially gapless.

3 Proofs of the main theorems

3.1 Unitary invariance of the Witten index (Lemma [2])

We prove the unitary invariance of the Witten index (Lemma [2]). Note that the special case of this invariance principle for unitary $U$ can be found in [Suz19 Corollary 3.6], the proof of which makes use of a spectral mapping theorem for chirally symmetric unitary operators [SS16, SS19]. We give the following direct proof instead:

Proof of Lemma [2] Let $(\Gamma, U), (\Gamma', U')$ be two unitarily equivalent chiral pairs on a Hilbert space $\mathcal{H}$. That is, there exists a unitary operator $\epsilon$ on $\mathcal{H}$, such that $(\Gamma', U') = (\epsilon^* \Gamma \epsilon, \epsilon^* U \epsilon)$. Let $\mathcal{H}_\pm := \text{ker}(\Gamma \mp 1)$, and let $\mathcal{H}'_\pm := \text{ker}(\Gamma' \mp 1)$. We may assume that the operator $\epsilon$ admits the following block-operator matrix representation;

$$\epsilon = \begin{pmatrix} \epsilon_+ & \epsilon_- \\ \epsilon_- & \epsilon_+ \end{pmatrix}, \quad \epsilon_+ : \mathcal{H}'_+ \to \mathcal{H}_+ \quad \epsilon_- : \mathcal{H}'_- \to \mathcal{H}_-.$$ 

Recall that the operators $U, U'$ admit the following block-operator matrix representations respectively according to (2.1):

$$U = \begin{pmatrix} R_1 & iQ_0 \\ iQ_0 & R_2 \end{pmatrix}_{\mathcal{H}_+ \oplus \mathcal{H}_-}, \quad U' = \begin{pmatrix} R'_1 & i(Q'_0)^* \\ iQ'_0 & R'_2 \end{pmatrix}_{\mathcal{H}'_+ \oplus \mathcal{H}'_-}.$$ 

Since $0 = \epsilon \Gamma' - \Gamma \epsilon$, where $\Gamma = 1 \oplus (-1)$ and $\Gamma' = 1 \oplus (-1)$, we obtain

$$0 = \begin{pmatrix} \epsilon_+ & \epsilon_- \\ \epsilon_- & \epsilon_+ \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} \epsilon_+ & \epsilon_- \\ \epsilon_- & \epsilon_+ \end{pmatrix} = \begin{pmatrix} \epsilon_+ & 0 \\ 0 & \epsilon_+ \end{pmatrix} + \begin{pmatrix} 0 & \epsilon_- \\ -\epsilon_- & 0 \end{pmatrix} = \begin{pmatrix} 0 & -2\epsilon_- \\ 2\epsilon_- & 0 \end{pmatrix}.$$ 

This implies $\epsilon = \epsilon_+ \oplus \epsilon_- : \mathcal{H}'_+ \oplus \mathcal{H}'_- \to \mathcal{H}_+ \oplus \mathcal{H}_-$, and so

$$\epsilon^* U \epsilon = (\epsilon_+^* \oplus \epsilon_-^*) U (\epsilon_+ \oplus \epsilon_-) = \begin{pmatrix} \epsilon_+^* R_1 \epsilon_+ & i\epsilon_+^* Q_0^* \epsilon_- \\ i\epsilon_+^* Q_0 \epsilon_+ & \epsilon_+^* R_2 \epsilon_- \end{pmatrix} = \begin{pmatrix} R'_1 & i(Q'_0)^* \\ iQ'_0 & R'_2 \end{pmatrix}.$$ 

Since $Q'_0 = \epsilon^* Q_0 \epsilon_+$, where $\epsilon_+, \epsilon_-$ are unitary, we have that $Q_0$ is Fredholm if and only if so is $Q'_0$. In this case, $\text{ind} Q_0 = \text{ind} Q'_0$. The claim follows. □
3.2 Unitary transform of the Mochizuki–Kim-Obuse model (Theorem B)

Proof of Theorem B. We shall make use of the fact that the operator $S$ commutes with any diagonal block-operator matrices in this proof. We have

$$U_{mko} = S(G\Phi)C_2 S(G^{-1}\Phi)$$

where $G\Phi$ denotes the second Pauli matrix, then $\sigma_2 = 1$, and so

$$U_{mko} = (S\sigma_2)\sigma_2 (ae^{-2\gamma y(-1)} + b\ast e^{-\gamma y(-1)}) (S\sigma_2) (\sigma_2 C_1)$$

If we let $\eta := (\sigma_2 C_1) (S\sigma_2)$, where $\sigma_2 C_1$ and $S\sigma_2$ are unitary invariants, then

$$\eta^* U_{mko}\eta = (S\sigma_2) (\sigma_2 C_1) (S\sigma_2) (ae^{-2\gamma y(-1)} + b\ast e^{-\gamma y(-1)}) (S\sigma_2) (\sigma_2 C_1) (\sigma_2 C_1) (S\sigma_2)$$

It remains to compute $(S\sigma_2) (\sigma_2 C_1) (S\sigma_2)$;

$$(S\sigma_2) (\sigma_2 C_1) (S\sigma_2) = \begin{pmatrix} 0 & -iL \\ iL & 0 \end{pmatrix} \begin{pmatrix} \sin \theta_1 & -i \cos \theta_1 \\ i \cos \theta_1 & -\sin \theta_1 \end{pmatrix} \begin{pmatrix} 0 & -iL \\ iL & 0 \end{pmatrix} = \Gamma_2.$$

If we let $\Gamma_{mko} := \eta \Gamma_2 \eta^*$, then $\eta^* U_{mko}\eta = \Gamma_2$. The claim follows.

3.3 Classification of the topological invariants (Theorem C)

3.3.1 Strictly local operators

To prove Theorem C let us first introduce one preliminary concept beforehand. With the obvious orthogonal decomposition $L^2(\mathbb{Z}, \mathbb{C}^n) = \bigoplus_{j=1}^n L^2(\mathbb{Z}, \mathbb{C})$ in mind, we shall consider an operator of the form

$$A = \begin{pmatrix} \Sigma_{y=-k}^k a_{11}(y, \cdot) L^y & \cdots & \Sigma_{y=-k}^k a_{1n}(y, \cdot) L^y \\ \vdots & \ddots & \vdots \\ \Sigma_{y=-k}^k a_{n1}(y, \cdot) L^y & \cdots & \Sigma_{y=-k}^k a_{nn}(y, \cdot) L^y \end{pmatrix}.$$
where $k$ is a finite natural number, and where each $a_{ij}(y, \cdot) = (a_{ij}(y, x))_{x \in \mathbb{Z}}$ is an arbitrary bounded $\mathbb{C}$-valued sequence viewed as a multiplication operator on $l^2(\mathbb{Z}, \mathbb{C}) = \bigoplus_{x \in \mathbb{Z}} \mathbb{C}$. An operator of the form (7) will be referred to as a (one-dimensional) strictly local operator following [CGG+18 §1.2].

**Theorem 8** (Tan20 Theorem A). Let $A$ be a strictly local operator of the form (7) with the property that the following two-sided limits exist:

$$a_{ij}(y, \pm \infty) := \lim_{x \to \pm \infty} a_{ij}(y, x) \in \mathbb{C}, \quad i, j = 1, \ldots, n, \quad -k \leq y \leq k.$$  

(8)

Let

$$A(\pm \infty) := \begin{pmatrix} \sum_{y=-k}^{k} a_{11}(y, \pm \infty)L^y & \ldots & \sum_{y=-k}^{k} a_{1n}(y, \pm \infty)L^y \\ \vdots & \ddots & \vdots \\ \sum_{y=-k}^{k} a_{n1}(y, \pm \infty)L^y & \ldots & \sum_{y=-k}^{k} a_{nn}(y, \pm \infty)L^y \end{pmatrix},$$

(9)

$$\hat{A}(z, \pm \infty) := \begin{pmatrix} \sum_{y=-k}^{k} a_{11}(y, \pm \infty)z^y & \ldots & \sum_{y=-k}^{k} a_{1n}(y, \pm \infty)z^y \\ \vdots & \ddots & \vdots \\ \sum_{y=-k}^{k} a_{n1}(y, \pm \infty)z^y & \ldots & \sum_{y=-k}^{k} a_{nn}(y, \pm \infty)z^y \end{pmatrix}, \quad z \in \mathbb{T}.$$  

(10)

Then the following assertions hold true:

(i) We have that $A$ is Fredholm if and only if $\mathbb{T} \ni z \mapsto \det \hat{A}(z, \star) \in \mathbb{C}$ is nowhere vanishing on $\mathbb{T}$ for each $\star = \pm \infty$. In this case, the Fredholm index of $A$ is given by

$$\text{ind} (A) = \text{wn} \left( \det \hat{A}(\cdot, +\infty) \right) - \text{wn} \left( \det \hat{A}(\cdot, -\infty) \right),$$

(11)

where $\text{wn} \left( \det \hat{A}(\cdot, \star) \right)$ denotes the winding number of the continuous function $\mathbb{T} \ni z \mapsto \det \hat{A}(z, \star) \in \mathbb{C}$ with respect to the origin.

(ii) The essential spectrum of $A$ is given by

$$\sigma_{\text{ess}}(A) = \sigma_{\text{ess}}(A(\cdot, -\infty)) \cup \sigma_{\text{ess}}(A(\cdot, +\infty)),$$

$$\sigma_{\text{ess}}(A(\star)) = \bigcup_{z \in \mathbb{T}} \sigma(\hat{A}(z, \star)), \quad \star = \pm \infty.$$

Theorem 8 can be viewed as an abstract form of the one-dimensional bulk-boundary correspondence [CGG+18 Corollary 4.3] (see [Tan20 §2] for details).

### 3.3.2 Proof of Theorem 8

**Notation 9.** We shall make use of the notation introduce in Definition 4. For notational simplicity, we use the following notation throughout §3.3.2.

$$(\Gamma, U) := (\Gamma_m, U_m), \quad C := \begin{pmatrix} a_1 & \beta \\ \beta & a_2 \end{pmatrix} := \begin{pmatrix} e^{-\gamma(\pm 1)}a & e^{-\gamma(\pm 1)}b \\ e^{-\gamma(\pm 1)}b & -e^{\gamma(\pm 1)} \end{pmatrix}.$$  

With the above notation, the operator $U$ can be written as $U = \Gamma C$. 

In order to compute \( \text{ind}(\Gamma,U) \) we shall closely follow [Tan20] §3.2. Note first that the underlying Hilbert space \( \ell^2(\mathbb{Z}, C^2) \) admits the following two orthogonal decompositions:

\[
\ell^2(\mathbb{Z}, C^2) = \ker(\Gamma - 1) \oplus \ker(\Gamma + 1) = \ell^2(\mathbb{Z}) \oplus \ell^2(\mathbb{Z}),
\]

where \( \ker(\Gamma - 1) \neq \ell^2(\mathbb{Z}) \). On one hand, the imaginary part \( Q \) of \( U \) admits an off-diagonal block operator matrix representation with respect to the former decomposition as in the second equality of (11), where the Fredholm index of \( Q_0 : \ker(\Gamma - 1) \to \ker(\Gamma + 1) \) is by definition \( \text{ind}(\Gamma, U) \). On the other hand, the same operator \( Q \) can not be expressed as an off-diagonal block-operator matrix with respect to the latter decomposition. The unitary invariance of the Witten index (Lemma 2) motivates us to construct a unitary operator \( \epsilon \) in such a way that the imaginary part \( \epsilon^* Q \epsilon \) of the new chiral pair \( (\epsilon^* \Gamma \epsilon, \epsilon^* U \epsilon) \) become off-diagonal with respect to \( \ell^2(\mathbb{Z}) \oplus \ell^2(\mathbb{Z}) \).

**Lemma 10.** Let \( R, Q \) be the real and imaginary parts of \( U \) respectively. For each \( x \in \mathbb{Z} \), let \( \theta(x) \) be any real number satisfying \( q(x) = |q(x)|e^{i\theta(x)} \), and let \( p_x(x) := \sqrt{1 \pm p(x)} \). Let

\[
\begin{align*}
-2iQ_{\epsilon_{0}} := p_xe^{i\theta}L^m\beta_p + p_\beta L^{-m}e^{-i\theta}p_- - |q|(\alpha_1 - \alpha_2(\cdot + m)),
2R_{\epsilon_{0}} := p_xe^{i\theta}L^m\beta_p + p_\beta L^{-m}e^{-i\theta}p_- + p_\beta^2\alpha_1 + p_\beta^2\alpha_2(\cdot + m),
2R_{\epsilon_{0}} := p_xe^{i\theta}L^m\beta_p + p_\beta L^{-m}e^{-i\theta}p_- - p_\beta^2\alpha_1 - p_\beta^2\alpha_2(\cdot + m).
\end{align*}
\]

Then there exists a unitary operator \( \epsilon \) on \( \ell^2(\mathbb{Z}, C^2) \), such that the following block-operator matrix representations hold true with respect to \( \ell^2(\mathbb{Z}, C^2) = \ell^2(\mathbb{Z}) \oplus \ell^2(\mathbb{Z}) \):

\[
\begin{align*}
\epsilon^* \Gamma \epsilon &= \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, & \epsilon^* U \epsilon &= \begin{pmatrix} R_{\epsilon_{0}} & iQ_{\epsilon_{0}} \\ iQ_{\epsilon_{0}} & R_{\epsilon_{0}} \end{pmatrix}, & \epsilon^* R \epsilon &= \begin{pmatrix} R_{\epsilon_{0}} & 0 \\ 0 & R_{\epsilon_{0}} \end{pmatrix}, & \epsilon^* Q \epsilon &= \begin{pmatrix} 0 & Q_{\epsilon_{0}} \\ Q_{\epsilon_{0}} & 0 \end{pmatrix}.
\end{align*}
\]

Moreover, the chiral pair \( (\Gamma, U) \) is Fredholm if and only if \( Q_{\epsilon_{0}} \) is Fredholm. In this case,

\[
\text{ind}(\Gamma, U) = \text{ind} Q_{\epsilon_{0}}.
\]

As we shall see below, the derivation of the index formula (15) only requires the boundedness of the given sequences \( \gamma, p, a, q, b \), and so (15) turns out to be redundant. Note, however, that this assumption (A5) is necessary to prove the index formula (C2).

**Proof.** Note first that \( \Gamma \) can be written as

\[
\Gamma = \begin{pmatrix} p & qL^m \\ L^{-m}q^* - p(\cdot - m) \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & -m \end{pmatrix} \begin{pmatrix} p & q \\ q^* & -p \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & L^m \end{pmatrix},
\]

where the middle matrix on the right hand side of the second equality admits the following diagonalisation. For each \( x \in \mathbb{Z} \) we have

\[
\epsilon_{0}(x) := \begin{pmatrix} p(x) & q(x) \\ q(x)^* & -p(x) \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & -m \end{pmatrix} \begin{pmatrix} p_+(x) & p_-(x) \\ p_-(x) & p_+(x) \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & e^{-i\theta(x)} \end{pmatrix} \begin{pmatrix} p_+ & p_- \\ p_- & p_+ \end{pmatrix}.
\]

Since \( \epsilon_{0} := \bigoplus_{x} \epsilon_{0}(x) \) is unitary, the following operator is also unitary;

\[
\epsilon := \begin{pmatrix} 1 & 0 \\ 0 & L^{-m} \end{pmatrix} \epsilon_{0} = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 0 \\ 0 & L^{-m}e^{-i\theta} \end{pmatrix} \begin{pmatrix} p_+ & p_- \\ p_- & p_+ \end{pmatrix}.
\]
It follows from the first equality that

$$e^{\epsilon} = e^{\epsilon} \left( \begin{array}{cc} 1 & 0 \\ 0 & L^m \end{array} \right) \left( \begin{array}{cc} q & p \\ q^* & -p \end{array} \right) \left( \begin{array}{cc} 1 & 0 \\ 0 & L^{-m} \end{array} \right) \epsilon_0 = e^{\epsilon} \left( \begin{array}{cc} p & q \\ q^* & -p \end{array} \right) \epsilon_0 = \left( \begin{array}{cc} 1 & 0 \\ 0 & -1 \end{array} \right),$$

where the last equality follows from (10).

Given a bounded operator $X$ on $L^2(\mathbb{Z}, \mathbb{C}^2)$, we introduce the shorthand $X_\epsilon := e^{\epsilon} X e^{\epsilon}$.

With this convention in mind, we have $[I_\epsilon, R_\epsilon] = 0 = [I_\epsilon, Q_\epsilon]$, where $I_\epsilon = 1 \oplus (-1)$ with respect to $L^2(\mathbb{Z}, \mathbb{C}^2) = L^2(\mathbb{Z}) \oplus L^2(\mathbb{Z})$. It follows that we have the following representations:

$$R_\epsilon = \left( \begin{array}{cc} R_\epsilon' & 0 \\ 0 & R_\epsilon'' \end{array} \right), \quad Q_\epsilon = \left( \begin{array}{cc} Q_\epsilon' & 0 \\ 0 & Q_\epsilon'' \end{array} \right), \quad U_\epsilon = R_\epsilon + iQ_\epsilon = \left( \begin{array}{cc} R_\epsilon' + iQ_\epsilon' & i(Q_\epsilon'')' \\ iQ_\epsilon'' & R_\epsilon'' \end{array} \right).$$

(17)

It remains to show that the three operators $Q_\epsilon', R_\epsilon', R_\epsilon''$ introduced above coincide with the ones defined by the formulas (12)-(14). Note that

$$2C_\epsilon = I_\epsilon (2U_\epsilon) = \left( \begin{array}{cc} 1 & 0 \\ 0 & -1 \end{array} \right) \left( \begin{array}{cc} 2R_\epsilon' & 2i(Q_\epsilon'')' \\ 2iQ_\epsilon'' & 2R_\epsilon'' \end{array} \right) = \left( \begin{array}{cc} 2R_\epsilon' & 2i(Q_\epsilon'')' \\ 2iQ_\epsilon'' & -2R_\epsilon'' \end{array} \right).$$

(18)

It remains to compute $2C_\epsilon$. We have

$$2e^{\epsilon} \left( \begin{array}{c} a_1 \\ a_2 \end{array} \right) = \left( \begin{array}{c} p^2 a_1 + p^2 a_2 (\cdot + m) - |q| (a_1 - a_2 (\cdot + m)) \\ -|q| (a_1 - a_2 (\cdot + m)) p^2 a_1 + p^2 a_2 (\cdot + m) \end{array} \right),$$

$$2e^{\epsilon} \left( \begin{array}{c} 0 \\ \beta \end{array} \right) = \left( \begin{array}{c} p e^{i\theta} L^m \beta p_+ + p e^{i\theta} L^m e^{-i\theta} p_- - p e^{i\theta} L^m \beta p_+ + p e^{i\theta} L^m e^{-i\theta} p_- \\ p e^{i\theta} L^m \beta p_+ - p e^{i\theta} L^m e^{-i\theta} p_- - p e^{i\theta} L^m \beta p_+ - p e^{i\theta} L^m e^{-i\theta} p_- \end{array} \right).$$

It follows from the above two equalities that

$$2C_\epsilon = 2e^{\epsilon} \left( \begin{array}{c} a_1 \\ a_2 \end{array} \right) + 2e^{\epsilon} \left( \begin{array}{c} 0 \\ \beta \end{array} \right) = \left( \begin{array}{c} 2R_\epsilon' \\ 2iQ_\epsilon'' \end{array} \right).$$

(19)

By comparing (18) with (19), we see that (17) also holds true without the superscript $'$.

Note that $L^2(\mathbb{Z}, \mathbb{C}^2) = L^2(\mathbb{Z}) \oplus L^2(\mathbb{Z})$ can be identified with the orthogonal sum $L^2(\mathbb{Z}) \oplus \{0\} \oplus \{0\} \oplus L^2(\mathbb{Z})$ through the following unitary transform:

$$L^2(\mathbb{Z}, \mathbb{C}^2) \ni (\Psi_1, \Psi_2) \mapsto (\Psi_1, 0, 0, \Psi_2) \in L^2(\mathbb{Z}) \oplus \{0\} \oplus \{0\} \oplus L^2(\mathbb{Z}).$$

It is then easy to show that the operator $Q_\epsilon$ admits the following block-operator matrix representations:

$$Q_\epsilon = \left( \begin{array}{cc} 0 & Q_\epsilon' \\ Q_\epsilon'' & 0 \end{array} \right)_{L^2(\mathbb{Z}) \oplus L^2(\mathbb{Z})} = \left( \begin{array}{cc} 0 & 0 & 0 & Q_\epsilon'' \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ Q_\epsilon'' & 0 & 0 & 0 \end{array} \right)_{L^2(\mathbb{Z}) \oplus \{0\} \oplus \{0\} \oplus L^2(\mathbb{Z})}.$$
It follows from (20)-(21) that \( Q''_{e_0} \) is an off-diagonal block-operator matrix of the form:

\[
Q''_{e_0} = \begin{pmatrix} 0 & \Theta \\ \Theta & 0 \end{pmatrix}.
\]

Since \( \Theta \) is a Fredholm operator of zero index, we have that \( Q''_{e_0} \) is Fredholm if and only if \( Q_{e_0} \) is Fredholm. In this case, we have \( \text{ind} Q''_{e_0} = \text{ind} Q_{e_0} + \text{ind} \Theta = \text{ind} Q_{e_0} + 0 = \text{ind} Q_{e_0} \).

The claim follows from Lemma 2.

It remains to compute the Fredholm index of the strictly local operator \( Q_{e_0} \) given by (12), where \( \theta = (\theta(x))_{x \in \mathbb{Z}} \) can be any \( \mathbb{R} \)-valued sequence satisfying \( q(x) = |q(x)|e^{i\theta(x)} \) for each \( x \in \mathbb{Z} \). Note that Theorem(i) is not immediately applicable to this operator \( Q_{e_0} \), since it is not necessarily true that \( \theta \) is convergent. More precisely, for each \( \star = \pm \infty \), if \( q(\star) \neq 0 \), then we can explicitly construct \( \theta \) in such a way that \( \theta(\star) = \lim_{x \to \star} \theta(x) \) holds true. On the other hand, if \( q(\star) = 0 \), then the same conclusion cannot be drawn in general. In order to overcome this hindrance, we shall closely follow [Tan20, Lemma 3.4];

**Lemma 11.** There exist two \( \mathbb{R} \)-valued sequences \( \theta_+ = (\theta_+(x))_{x \in \mathbb{Z}}, \theta_- = (\theta_-(x))_{x \in \mathbb{Z}}, \) such that

\[
e^{-i\theta_+(x)}(-2Q_{e_0})e^{i\theta} = p_+p_+(\cdot + m)\beta(\cdot + m)e^{i(\theta_+(x) - \theta_+(\cdot + m))} + p_-p_-(\cdot - m)\beta(\cdot - m)e^{i(\theta_-(x) - \theta_-(\cdot - m))} - |q(\cdot)(x)| = \pm \infty,
\]

where the three coefficients of the above strictly local operator have the following limits for each \( \star = \pm \infty \):

\[
\begin{align*}
\lim_{x \to \star} (p_+p_+(\cdot + m)\beta(\cdot + m)e^{i(\theta_+(x) - \theta_+(\cdot + m))}) &= (1 + p(\star))\beta(\star)e^{i\theta(\star)}, \quad (23) \\
\lim_{x \to \star} (p_-p_-(\cdot - m)\beta(\cdot - m)e^{i(\theta_-(x) - \theta_-(\cdot - m))}) &= (1 - p(\star))\beta(\star)e^{-i\theta(\star)}, \quad (24) \\
\lim_{x \to \star} |q(x)(\cdot)(x)| &= 2|q(\star)|\beta(\star)e^{i\theta(\star)}. \quad (25)
\end{align*}
\]

**Proof.** For each \( x \in \mathbb{Z} \) we let

\[
\begin{align*}
\star(x) &:= \begin{cases}
\pm \infty, & x \geq 0, \\
-\infty, & x < 0,
\end{cases} \\
\theta_+(x) &:= \begin{cases}
\theta(x), & p(\star(x)) = \pm 1, \\
0, & p(\star(x)) \neq \pm 1.
\end{cases}
\end{align*}
\]

Note that (22) immediately follows from (12). We let

\[
\Theta_1 := \theta - \theta_+ + \theta_-(\cdot + m), \quad \Theta_2 := \theta(\cdot - m) - \theta_-(\cdot - m) + \theta_+, \quad \Theta_3 := \theta_- - \theta_+.
\]

It suffices to prove the following equalities:

\[
\begin{align*}
\lim_{x \to \star} (p_+(\cdot + m)e^{i\theta_+(x)}) &= (1 + p(\star))e^{i\theta(\star)}, \quad (26) \\
\lim_{x \to \star} (p_-(\cdot - m)e^{-i\theta_-(x)}) &= (1 - p(\star))e^{-i\theta(\star)}, \quad (27) \\
\lim_{x \to \star} |q(x)|e^{i\theta_+(x)} &= |q(\star)|. \quad (28)
\end{align*}
\]

Let \( \star = \pm \infty \), and let \( x \) be any integer satisfying \( |x| > |m| \). If \( |p(\star)| < 1 \), then \( \theta_+(x) = \theta_-(x) = 0 \). In this case, (26)-(28) follow from the fact that as \( x \to \star \) we have \( \Theta_j(x) \to \theta(\star) \) for each \( j = 1, 2, \) and \( \Theta_3(x) \to 0 \). On the other hand, if \( |p(\star)| = 1 \), then \( q(\star) = 0 \), and so (28)
becomes trivial. We need to check the following cases separately: $p(\star) = -1$ and $p(\star) = +1$. If $p(\star) = -1$, then (26) holds trivially, and (27) follows from $\theta_\gamma(x - m) = \theta(x - m)$ and $\theta_\delta(x) = 0 = \theta(\star)$, where the last equality follows from (A6). Similarly, if $p(\star) = +1$, then (27) holds trivially, and (26) follows from $\theta_\delta(x) = \theta(x)$ and $\theta_\gamma(x + m) = 0 = \theta(\star)$.

Since the Fredholm index is invariant under multiplication by invertible operators,

$$\text{ind } (e^{-iQ_{\theta_\delta}e^{i\theta_\gamma}}) = \text{ind } Q_{\theta_\delta} = \text{ind } (\Gamma, U).$$

We are now in a position to apply Theorem 8 (i) to $A := e^{-iQ_{\theta_\delta}e^{i\theta_\gamma}}$. Since the two-sided limits of the coefficients of $-2iA_{\pm}$ are given respectively by (23)-(25), we introduce the following notation according to (10):

$$c(\star) := |q(\star)|a(\star) \cosh(2\gamma(\star)), \quad (29)$$

$$-2i f(z, \star) := \langle p(\star) + 1 \rangle b(\star) e^{i(\theta_\gamma + \theta_\delta)z^m} + (p(\star) - 1) b(\star)^* e^{-i(\theta_\gamma + \theta_\delta)z^m} - 2 c(\star), \quad (30)$$

where $\star = \pm \infty$ and $z \in \mathbb{T}$. It follows from Theorem 8 (i) that $A = e^{-iQ_{\theta_\delta}e^{i\theta_\gamma}}$ is Fredholm if and only if $f(\cdot, \star)$ is nowhere vanishing on $\mathbb{T}$ for each $\star = \pm \infty$. In this case, we have

$$\text{ind } (\Gamma, U) = \text{ind } A = \text{wn}(f(\cdot, +\infty)) - \text{wn}(f(\cdot, -\infty)), \quad (31)$$

where the last equality is a special case of (11). It remains to compute the winding number of $f(\cdot, \star)$.

**Lemma 12.** Let $\Gamma, C$ be as in Theorem 8 and let $\star = \pm \infty$. Let $f(\cdot, \star)$ be defined by (30)-(29), and let $p_\gamma(\star)$ be defined by (31). Then the image of $\mathbb{T} \ni z \mapsto f(z, \star) \in \mathbb{C}$ does not contain the origin if and only if $|p_\gamma(\star)| \neq |a(\star)|$. In this case, we have

$$\text{wn}(f(\cdot, \star)) = \begin{cases} m \cdot \text{sgn } p(\star), & |p_\gamma(\star)| > |a(\star)|, \\ 0, & |p_\gamma(\star)| < |a(\star)|. \end{cases} \quad (32)$$

**Proof.** Let us first prove that the image of $\mathbb{T} \ni z \mapsto f(z, \star) \in \mathbb{C}$ does not contain the origin if and only if $|p(\star)b(\star)| \neq |c(\star)|$, and

$$\text{wn}(f(\cdot, \star)) = \begin{cases} m \cdot \text{sgn } p(\star), & |p(\star)b(\star)| > |c(\star)|, \\ 0, & |p(\star)b(\star)| < |c(\star)|. \end{cases} \quad (33)$$

Let us consider the following function on $\mathbb{R}$:

$$2F(s) := (|p(\star)b(\star)| + |b(\star)|) e^{is} + (|p(\star)b(\star)| - |b(\star)|) e^{-is}$$

$$= 2|p(\star)b(\star)| \cos s + i2|b(\star)| \sin s, \quad s \in \mathbb{R}.$$ 

Since $p(\star) = \text{sgn } p(\star)|p(\star)|$ and $b(\star) = e^{i\theta(\star)}|b(\star)|$, for each $t \in [0, 2\pi]$ we have

$$-2i f(e^{it}, \star) + 2c(\star) = (p(\star) + 1)b(\star)e^{i\theta(\star)e^{int}} + (p(\star) - 1)b(\star)^* e^{-i\theta(\star)e^{-int}}$$

$$= \text{sgn } p(\star) \cdot 2F(\text{sgn } p(\star)(\theta(\star) + \theta'(\star) + mt)).$$

It follows that $-i f(e^{it}, \star) = \text{sgn } p(\star) \cdot F(\text{sgn } p(\star)(\theta(\star) + \theta'(\star) + mt)) - c(\star)$ for each $t \in [0, 2\pi]$, where the constant $-i$ does not play any significant role in this proof. If $p(\star)b(\star) = 0$, then the image of the function $[0, 2\pi] \ni t \mapsto -i f(e^{it}, \star) \in \mathbb{C}$ coincides with that of the vertical line segment $[-1, 1] \ni t \mapsto -c(\star) + it|b(\star)| \in \mathbb{C}$ passing
through \(-c(\bullet)\). That is, the image of \(f(\cdot, \bullet)\) does not contain the origin if and only if \(|c(\bullet)| \neq |p(\bullet)b(\bullet)|\), and in this case \(\text{wn}(f(\cdot, \bullet)) = 0\). This is a special case of \([33]\).

On the other hand, if \(p(\bullet)b(\bullet) \neq 0\), then the image of the curve \([0, 2\pi] \ni t \mapsto -i f(e^{it}, \bullet) \in \mathbb{C}\) is the ellipse in Fig. 3 with \(m \cdot \text{sgn} p(\bullet)\) being its winding number with respect to the center \(-c(\bullet)\) on the real axis;

\[\text{Fig. 3 The above figure shows the image of the curve } [0, 2\pi] \ni t \mapsto -i f(e^{it}, \bullet) \in \mathbb{C}.\]

If \(|p(\bullet)b(\bullet)| > |c(\bullet)|\), then the origin is inside the interior of the ellipse, and so \(\text{wn}(f(\cdot, \bullet)) = \text{wn}(-if(\cdot, \bullet)) = \text{sgn} p(\bullet)\). If \(|p(\bullet)b(\bullet)| < |c(\bullet)|\), then the origin is inside the exterior of the ellipse, and so \(\text{wn}(f(\cdot, \bullet)) = 0\). Clearly, the ellipse \(-if(\cdot, \bullet)\) goes through the origin if and only if \(|p(\bullet)b(\bullet)| = |c(\bullet)|\).

It remains to check that \([32]\) coincides with \([33]\). If the notation \(\succ, =, <\) simultaneously denotes \(\succ, =, <\), then \(|p(\bullet)b(\bullet)| \leq |c(\bullet)|\) if and only if \(p(\bullet)^2(1 - a(\bullet)^2) \leq |q(\bullet)|a(\bullet)^2 \cosh^2(2\gamma(\bullet))\) if and only if \(p(\bullet)^2 \leq a(\bullet)^2(p(\bullet)^2 + |q(\bullet)|^2 \cosh^2(2\gamma(\bullet)))\).

Rearranging the last expression gives \(|p(\gamma)(\bullet)| \leq |a(\bullet)|\). The claim follows. \(\square\)

**Proof of Theorem C (i).** The index formula \([C2]\) immediately follows from \([31]\) and \([32]\). \(\square\)

It might be possible to give another proof for the index formula \([C2]\) by making use of the recent developments of the scattering-theoretic techniques for discrete-time quantum walks [Suz16], [RST17], [RST18], [MSS18b], [Mor19], [Wad20]. This possibility is briefly mentioned in [ST196] \([6]\).

3.3.3 **Proof of Theorem C (ii)**

**Proof of Theorem C (ii).** Note first that \(U_m\) is a strictly local operator of the following form;

\[U_m = \begin{pmatrix} pe^{-2y(+1)a + qL^me^{-\gamma(+1)b} & pe^{-\gamma(-1)b} - qL^me^{2}\gamma a \\ L^{-m}q^e^{-2y(+1)a} - p(-m)e^{-\gamma(+1)b} & L^{-m}q^e^{-\gamma(-1)b} + p(-m)e^{2}\gamma a \end{pmatrix}.\]

It follows from Theorem \([8](ii)\) that

\[\sigma_{\text{etz}}(U_m) = \sigma_{\text{etz}}(U_m(-\infty)) \cup \sigma_{\text{etz}}(U_m(+\infty)),\]

\[\sigma_{\text{etz}}(U_m(\bullet)) = \bigcup_{\zeta \in \mathbb{T}} \sigma \left(\hat{U}_m(z, \bullet)\right), \quad \bullet = \pm \infty,\]
Then the characteristic equation (34) becomes

\[ U_m(\star) := \begin{pmatrix} q(\star)b(\star)L^m + p(\star)a(\star)e^{-2\gamma(\star)} & -(q(\star)a(\star)e^{2\gamma(\star)}L^m - p(\star)b(\star)) \\ q(\star)a(\star)e^{-2\gamma(\star)}L^{-m} - p(\star)b(\star) & q(\star)b(\star)e^{2\gamma(\star)}L^{-m} + p(\star)a(\star)e^{2\gamma(\star)} \end{pmatrix}, \]

\[ \hat{U}_m(z, \star) := \begin{pmatrix} q(\star)b(\star)z^m + p(\star)a(\star)e^{-2\gamma(\star)} & -(q(\star)a(\star)e^{2\gamma(\star)}z^m - p(\star)b(\star)) \\ q(\star)a(\star)e^{-2\gamma(\star)}z^{-m} - p(\star)b(\star) & q(\star)b(\star)e^{2\gamma(\star)}z^{-m} + p(\star)a(\star)e^{2\gamma(\star)} \end{pmatrix}. \]

This equation motivates us to introduce the following notation:

\[ \{ X_1(e^{it}), X_2(e^{it}) \} = \hat{U}_m(e^{it}, \star). \]

Let \( \star = \pm \infty \) be fixed. It remains to compute \( \sigma'(*) := \bigcup_{t \in [0, 2\pi]} \sigma \left( \hat{U}_m(e^{it}, \star) \right) \). We let

\[ \hat{U}_m(e^{it}, \star) := \begin{pmatrix} X_1(e^{it}) - Y_1(e^{it}) \\ Y_2(e^{it}) - X_2(e^{it}) \end{pmatrix}, \quad t \in [0, 2\pi]. \]

We get the following characteristic equation;

\[ \det(\hat{U}_m(e^{it}, \star) - \lambda) = \lambda^2 - (X_1(e^{it}) + X_2(e^{it}))\lambda + X_1(e^{it})X_2(e^{it}) + Y_1(e^{it})Y_2(e^{it}). \]  

Since the product \( q(*)b(*) \) can be written as \( q(*)b(*) = |q(*)b(*)|e^{i(\theta(*) + \theta'(*) + it)} \) by \( (36) \), we obtain the following two equalities:

\[ X_1(e^{it}) + X_2(e^{it}) = 2|q(*)b(*)| \cos(\theta(*) + \theta'(*) + mt) + 2p(*)a(*) \cos(2\gamma(*)), \]

\[ X_1(e^{it})X_2(e^{it}) + Y_1(e^{it})Y_2(e^{it}) = 1. \]

Then the characteristic equation (34) becomes

\[ \lambda^2 - 2(p(*)a(*) \cosh(2\gamma(*)) + |q(*)b(*)| \cos(\theta(*) + \theta'(*) + mt))\lambda + 1 = 0. \]  

This equation motivates us to introduce the following notation:

\[ \Lambda(*) := p(*)a(*) \cosh(2\gamma(*)) + |q(*)b(*)|, \quad -1 \leq s \leq 1, \]

\[ \lambda_\pm(*) := \Lambda(*) \pm \sqrt{\Lambda(*)^2 - 1}, \quad -1 \leq s \leq 1. \]

Indeed, (35) becomes \( \lambda^2 - 2\Lambda(*) \cos(\theta(*) + \theta'(*) + mt))\lambda + 1 = 0 \) with the above notation, and so \( \sigma \left( \hat{U}_m(e^{it}, \star) \right) \) is a finite set consisting of only of \( \lambda_\pm(*) \) for each \( t \in [0, 2\pi] \).

We have

\[ \sigma'(*) = \bigcup_{t \in [0, 2\pi]} \sigma \left( \hat{U}_m(e^{it}, \star) \right) = \bigcup_{s \in [-1, 1]} \{ \lambda_\pm(*) \} = \bigcup_{s \in [-1, 1]} \{ \lambda_\pm(*) \} \bigcup_{s \in [-1, 1]} \{ \lambda_\pm(*) \} \bigcup_{s \in [-1, 1]} \{ \lambda_\pm(*) \}. \]

where the second equality follows from the fact that \( [0, 2\pi] \) is surjective and the last equality follows from \( \lambda_\pm(*) \lambda_\pm(*) = 1 \) for each \( t \in [0, 2\pi] \). It follows that \( \sigma'(*) \) coincides with the set \( \sigma(*) \) given by \( (36) \). Note first that \( \Lambda_\pm(*), \Lambda_\pm(*) \] \( \in [-1, \infty) \) follows from

\[ -1 \leq |q(*)b(*)| \leq |a(*)b(*)| \cosh(2\gamma(*)) - |q(*)b(*)| = \Lambda_\pm(*) \leq \Lambda_\pm(*). \]

If \( p(*)a(*) = 0 \), then \( \Lambda_\pm(*) = |q(*)b(*)| \leq 1 \). This is a special case of Case I, since \( y_\pm(*) = y_\pm(*) = \infty \) according to \( (37) \). It remains to consider the case \( p(*)a(*) \neq 0 \). We shall make use of the fact that the hyperbolic cosine is an even function throughout. It follows from \( (37) \) that

\[ |p(*)a(*)| \cosh(2\gamma_\pm(*)) = 1 \pm |q(*)b(*)|. \]
Case I. If \(|\gamma(\bullet)| \leq \gamma_-(\bullet)| \), then

\[ \Lambda_+(\bullet) \leq |p(\bullet)\alpha(\bullet)| \cosh(2\gamma_-(\bullet)) + |q(\bullet)\beta(\bullet)| = 1, \]

where the first inequality follows from \(\cosh(2\gamma(\bullet)) \leq \cosh(2\gamma_-(\bullet))\) and the last equality follows from (35). Thus \([\Lambda_-(\bullet), \Lambda_+(\bullet)] \subseteq [-1, 1]\).

Case II. If \(\gamma_-(\bullet) < |\gamma(\bullet)| < \gamma_+(\bullet)\), then it follows from (35) that \(\Lambda_-(\bullet) < 1 < \Lambda_+(\bullet)\). It follows that the interval \([\Lambda_-(\bullet), \Lambda_+(\bullet)] \subseteq [-1, \infty)\) can be written as the following union;

\[ \{\Lambda_-(\bullet), \Lambda_+(\bullet)\} = [\Lambda_-(\bullet), 1] \cup [1, \Lambda_+(\bullet)]\]

Case III. If \(\gamma_+(\bullet) \leq |\gamma(\bullet)|\). Then \([\Lambda_-(\bullet), \Lambda_+(\bullet)] \subseteq [1, \infty)\) follows from

\[ 1 = |p(\bullet)\alpha(\bullet)| \cosh(2\gamma_+(\bullet)) - |q(\bullet)\beta(\bullet)| \leq \Lambda_-(\bullet), \]

where the first equality follows from (35) and the last inequality follows from \(\cosh(2\gamma_+(\bullet)) \leq \cosh(2\gamma(\bullet))\).

In the setting of 2-phase quantum walks, a typical computation of the essential spectrum makes use of the discrete Fourier transform and Weyl’s criterion for the essential spectrum (see, for example, [FFS17 Lemma 3.3]). Weyl’s criterion is applicable to, for example, non-compact perturbations (see, for example, [SS17]), but its usage is restricted to normal operators. This is why Weyl’s criterion is not suitable for Theorem C (ii).

4 Conclusion

4.1 Summary

The following is a brief summary of the present article. A chiral pair on a Hilbert space \(\mathcal{H}\) is by definition any pair \((I, U)\) of a unitary self-adjoint operator \(I : \mathcal{H} \to \mathcal{H}\) and a bounded operator \(U : \mathcal{H} \to \mathcal{H}\) satisfying the chiral symmetry condition (1). It is shown in §2.1 that we can assign to each abstract chiral pair \((I, U)\) the well-defined Witten index, denoted by \(\text{ind}(I, U)\) in this paper. Note that this assignation of the Fredholm index is a natural generalisation of the existing index theory for essentially unitary \(U\), where \(\text{ind}(I, U)\) is referred to as the symmetry index in the first three papers.

A motivating example for this paper is the non-unitary time-evolution \(U_{\text{mko}}\) defined by (2), where we assume the existence of the two-sided limits as in (3). Recall that this evolution operator is consistent with the experimental setup in [RBM]. It is shown in Theorem B that the operator \(U_{\text{mko}}\) forms a chiral pair with respect to the unitary self-adjoint operator \(I_{\text{mko}} := (\sigma_2C_1\sigma_2)I_2^\ast (\sigma_2C_1\sigma_2)^\ast\), where \(\sigma_2\) denotes the second Pauli matrix, and that the chiral pair \((I_{\text{mko}}, U_{\text{mko}})\) can be naturally generalised to another chiral pair \((I_m, U_m)\), where \(m\) can be any fixed integer. This new model \((I_m, U_m)\) also unifies several one-dimensional unitary quantum walk models as in §2.2.

Complete classification of the two associated topological invariants \(\text{ind}(I_m, U_m)\) and \(\sigma_{\text{ess}}(U_m)\) can be collectively found in Theorem C. Our classification of \(\text{ind}(I_m, U_m)\) makes use of an abstract form of the one-dimensional bulk-boundary correspondence, the precise statement of which can be found in Theorem C (i).

Finally, it is shown in Lemma H that given an abstract chiral pair \((I, U)\) with \(U\) being essentially unitary, we have that \(\text{ind}(I, U)\) is a well-defined Fredholm index if and only if \(U\) is essentially gapped in the sense that \(-1, +1 \notin \sigma_{\text{ess}}(U)\). It turns out that this characterisation
does not hold true in general, if $U$ fails to be essentially unitary. To put this into context, we consider the non-unitary evolution $U_{mko}$. It is shown in Example 7 that we can choose the asymptotic values $\theta_1(\pm \infty), \theta_2(\pm \infty), \gamma(\pm \infty)$, in such a way that $U_{mko}$ is essentially gapless, yet $\text{ind}(F, U)$ is a well-defined non-zero integer.

4.2 Discussion

The main results of the current paper may stimulate further developments in the rigorous mathematical studies of non-unitary discrete-time quantum walks. In particular, each of the following specific topics is the subject of another paper in preparation.

4.2.1 Further spectral analysis of the Mochizuki-Kim-Obuse model

Complete classification of $\sigma_{\text{ess}}(U_{mko})$ is given in this paper. In particular, we show that $\sigma_{\text{ess}}(U_{mko})$ is a subset of $\mathbb{T} \cup \mathbb{R}$, and that it depends only on the asymptotic values $\theta_1(\pm \infty), \theta_2(\pm \infty), \gamma(\pm \infty)$. Note, however, that it is not known to the authors whether or not the entire spectrum of $U_{mko}$ is also a subset of $\mathbb{T} \cup \mathbb{R}$. Detailed spectral analysis of the evolution-operator $U_{mko}$ may turn out to be difficult, partly because the discrete spectrum of such a non-normal operator is in general laborious to characterise (see, for example, [BC19 §III]). Note also that we expect the discrete spectrum to be non-stable under compact perturbations unlike $\sigma_{\text{ess}}(U_{mko})$.

4.2.2 Topologically protected bound states

Let $(F, U)$ be a chiral pair. If $U$ is unitary, then the non-zero vectors in $\ker(U \mp 1)$ can be referred to as topologically protected bound states [KRBD10, KBF+12, Suz19, ST19b, Mat20]. It is well-known that the Witten index $\text{ind}(F, U)$ gives a lower bound for the number of topologically protected bound states in the following precise sense (see, for example, [Suz19 Theorem 3.4 (ii)]);

$$|\text{ind}(F, U)| \leq \dim \ker(U - 1) + \dim \ker(U + 1), \quad (37)$$

where the chiral pair $(F, U)$ is assumed to be Fredholm. It follows that if $\text{ind}(F, U)$ is non-zero, then $U$ has at least one topologically protected bound state. Whether or not an estimate analogous to (37) holds true for non-unitary $U$ is an open problem.

Acknowledgements The authors are deeply indebted to the members of the Shinshu Mathematical Physics Group for extremely valuable discussions and comments. Our sincerely thanks go to T. Daniels for carefully reading the preprint. Y. T. was supported by JSPS KAKENHI Grant Number 20j22684.
