RIBBON TABLEAUX,
HALL-LITTLEWOOD FUNCTIONS,
QUANTUM AFFINE ALGEBRAS
AND UNIPOTENT VARIETIES

Alain Lascoux, Bernard Leclerc and Jean-Yves Thibon

Abstract

We introduce a new family of symmetric functions, which are $q$-analogues of products of Schur functions, defined in terms of ribbon tableaux.

These functions can be interpreted in terms of the Fock space representation $\mathcal{F}$ of $U_q(\hat{\mathfrak{sl}_n})$, and are related to Hall-Littlewood functions via the geometry of flag varieties. We present a series of conjectures, and prove them in special cases. The essential step in proving that these functions are actually symmetric consists in the calculation of a basis of highest weight vectors of $\mathcal{F}$ using ribbon tableaux.

1 Introduction

This article is devoted to the study of a new family of symmetric functions $H^{(k)}_{\lambda}(X; q)$, defined in terms of certain generalized Young tableaux, called ribbon tableaux, or rim-hook tableaux [46]. These objects, although unfamiliar, arise naturally in several contexts, and their use is implicit in many classical algorithms related to the symmetric groups (see e.g. Robinson’s book [43]). In particular, they can be applied to the description of the power-sum plethysm operators $\psi^k : f(\{x_i\}) \mapsto f(\{x_i^k\})$ on symmetric functions [3, 37], and this point of view suggests the definition of a natural $q$-analogue $\psi^k_q$ of $\psi^k$. This $q$-analogue turns out to make sense when the algebra of symmetric functions is interpreted as the bosonic Fock space representation of the quantum affine algebra $U_q(\widehat{\mathfrak{sl}}_k)$. Indeed, one can prove, building on recent work by Kashiwara, Miwa and Stern [47, 16], that the image $\psi^k_q(f)$ of any symmetric function by this operator, is a highest weight vector for $U_q(\widehat{\mathfrak{sl}}_k)$. In particular, the images $\psi^k_q(h_\lambda)$ of products of complete homogeneous functions have a simple combinatorial description, and can be used as a convenient basis of highest weight vectors.

The space of symmetric functions is endowed with a natural scalar product (the same as in the Fock space interpretation), and one can consider the adjoint $\varphi_q^k$ of the $q$-plethysm operator $\psi_q^k$. This operator divides degrees by $k$, and sends the Schur functions $s_{k\lambda}$ indexed by partitions of the form $k\lambda = (k\lambda_1, k\lambda_2, \ldots, k\lambda_r)$ onto a new basis, which is essentially the one considered in this paper. More precisely, $H^{(k)}_{\lambda}(X; q^{-2}) = \varphi_q^k(s_{k\lambda})$. It should be said, however, that our original definition was purely combinatorial, and that the connection with $U_q(\widehat{\mathfrak{sl}}_k)$ was understood only recently.

The $H$-functions are generalizations of Hall-Littlewood functions. We prove that for $k$ sufficiently large, $H^{(k)}_{\lambda} = Q^\prime_{\lambda}$, where $Q^\prime_{\lambda}$ is the adjoint basis of $P_{\lambda}$ for the standard scalar product. Moreover, we conjecture that the differences $H^{(k+1)}_{\lambda} - H^{(k)}_{\lambda}$ are nonnegative on the Schur basis, i.e. that the $H$-functions form a filtration of the $Q^\prime$-functions. In particular, the coefficients of $H$-functions on the Schur basis are conjectured to be polynomials with nonnegative integer coefficients.

The $Q^\prime$-functions are known to be related to a variety of topics in representation theory [10, 27, 28, 29, 40], algebraic geometry [12, 13, 24, 35, 45, 48], combinatorics [23, 30, 44] and mathematical physics [18, 21]. As a general rule, $q$-analogues related to quantum groups admit interesting interpretations when the parameter $q$ is specialized to the cardinality of a finite field, or to a complex root of unity. The $Q^\prime$-functions are no exception. In the first case, the coefficients $\check{K}_{\lambda\mu}(q)$ of $Q^\prime_{\mu}$ on the Schur basis are character values of the group $GL_n(F_q)$ [63], while in the second one, a factorization property reminiscent of Steinberg’s tensor product theorem leads to
combinatorial formulas for the Schur expansion of certain plethysms, in particular for $\psi^k(h_\mu)$ [23, 26].

On the basis of extensive numerical computations, we conjecture that the $H$-functions display the same behaviour with respect to specializations at roots of unity, giving this time plethysms $\psi^k(s_\lambda)$ of Schur functions by power sums. In fact, the $H$-functions were originally defined as $q$-analogues of products of Schur functions, being the natural generalization of those introduced in [1]. A combinatorial description of general $H$-functions on the Schur basis, similar to the one given in [2] in terms of Yamanouchi domino tableaux, would lead to a refined Littlewood-Richardson rule, compatible with cyclic symmetrization in the same way as the rule of [2] is compatible with symmetrized and antisymmetrized squares. This means that if one splits a tensor power $V_\lambda^\otimes k$ of an irreducible representation $V_\lambda$ of $U(n)$ into eigenspaces $E^{(i)}$ of the cyclic shift operator $v_1 \otimes v_2 \otimes \cdots \otimes v_k \mapsto v_2 \otimes v_3 \otimes \cdots \otimes v_k \otimes v_1$, each $E^{(i)}$ is a representation of $U(n)$ whose spectrum is given, according to the conjectures, by the coefficient of $q^i$ in the reduction modulo $1 - q^k$ of $H^{(k)}_\lambda(q)$.

All the conjectures are proved for $k = 2$ (domino tableaux) and for $k$ sufficiently large (the stable case). The case of domino tableaux follows from the combinatorial constructions of [1] and [19], while the stable case rely on the interpretation of Kostka-Foulkes polynomials in terms of characters of finite linear groups, and as Poincaré polynomials of certain algebraic varieties, in particular on the cell decompositions of these varieties found by N. Shimomura [45].

This article is structured as follows. In Section 2 we recall some properties of Hall-Littlewood functions, in particular their interpretation in terms of affine Hecke algebras and their connection with finite linear groups. In Section 3 we explain the connexion between plethysm and Hall-Littlewood functions at roots of unity, and in Section 4, we show how to translate these results in terms of ribbon tableaux. The application of ribbon tableaux to the construction of highest weight vectors in the Fock representation of $U_q(\mathfrak{sl}_n)$ is presented in Section 5, and connected to a recent construction of Kashiwara, Miwa and Stern [16]. In Section 6, we define the $H$-functions, and summarize their known or conjectural properties. Section 7 establishes these conjectures for $H$-functions of level 2, corresponding to domino tableaux. In Section 8, we recall Shimomura’s cell decompositions of unipotent varieties, and show the equivalence of his description of the Poincaré polynomials with a variant needed in the sequel. From this, we deduce that the $H$-functions of sufficiently large level are equal to Hall-Littlewood functions, which is also sufficient to prove all the conjectured properties in this case.

## 2 Hall-Littlewood functions

Our notations for symmetric functions will be essentially those of the book [37], to which the reader is referred for more details.

The original definition of Hall-Littlewood functions can be reformulated in terms of an action of the affine Hecke algebra $\widehat{H}_N(q)$ of type $A_{N-1}$ on the ring $\mathbb{C}[x_1^{\pm 1}, \ldots, x_N^{\pm 1}]$ [1].
The affine Hecke algebra $\tilde{H}_N(q)$ is generated by $T_i$, $i = 1, \ldots, N - 1$ and $y_i^{\pm 1}$, $i = 1, \ldots, N$, with relations

\[
\begin{align*}
T_i^2 &= (q - 1)T_i + q \\
T_iT_{i+1}T_i &= T_{i+1}T_it_iT_i \\
T_iT_j &= T_jT_i \quad (|j - i| > 1)
\end{align*}
\] (1)

If $\sigma = \sigma_{i_1}\sigma_{i_2}\cdots\sigma_{i_r}$ is a reduced decomposition of a permutation $\sigma \in S_N$, where $\sigma_i = (i, i + 1)$, one sets as usual $T_\sigma = T_{i_1}T_{i_2}\cdots T_{i_r}$, the result being independent of the reduced decomposition.

Let $\Delta_N(q) = \prod_{1 \leq i < j \leq N} (qx_i - x_j)$. Then, on one hand, the Hall-Littlewood polynomial $Q_\lambda(x_1, \ldots, x_N; q)$ indexed by a partition $\lambda$ of length $\leq N$ is defined by

\[
Q_\lambda = \frac{(1 - q)^{\ell(\lambda)}}{[m_0]q!} \sum_{\sigma \in S_N} \sigma \left( x^\lambda \frac{\Delta_N(q)}{\Delta_N(1)} \right)
\] (2)

where $m_0 = N - \ell(\lambda)$ and the $q$-integers are here defined by $[n]_q = (1 - q^n)/(1 - q)$.

On the other hand, $\tilde{H}_N(q)$ acts on $C[x_1^{\pm 1}, \ldots, x_N^{\pm 1}]$ by $y_i(f) = x_if$ and $T_i = (q - 1)\pi_i + \sigma_i$, where $\pi_i$ is the isobaric divided difference operator

\[
\pi_i(f) = \frac{x_1f - x_{i+1}\sigma_i(f)}{x_i - x_{i+1}},
\]

and it is shown in [3] that if one defines the $q$-symmetrizing operator $S^{(N)} \in \tilde{H}_N(q)$ by

\[
S^{(N)} = \sum_{\sigma \in S_N} T_\sigma,
\] (3)

then

\[
Q_\lambda(x_1, \ldots, x_N; q) = \frac{(1 - q)^{\ell(\lambda)}}{[m_0]q!} S^{(N)}(x^\lambda).
\] (4)

The normalization factor $1/[m_0]q!$ is here to ensure stability with respect to the adjunction of variables, and if we denote by $X$ the infinite set $X = \{x_1, x_2, \ldots, \}$ then $Q_\lambda(X; q) = \lim_{N \to \infty} Q_\lambda(x_1, \ldots, x_N; q)$.

The $P$-functions are defined by

\[
P_\lambda(X; q) = \frac{1}{(1 - q)^{\ell(\lambda)}[m_1]q! \cdots [m_n]q!} Q_\lambda(X; q)
\]

where $m_i$ is the multiplicity of the part $i$ in $\lambda$.

We consider these functions as elements of the algebra $\text{Sym} = \text{Sym}(X)$ of symmetric functions with coefficients in $C(q)$. In this paper, the scalar product $\langle, \rangle$ on $\text{Sym}$ will always be the standard one, for which the Schur functions $s_\lambda$ form an orthonormal basis.

We denote by $(Q'_\mu(X; q))$ the adjoint basis of $P_\lambda(X; q)$ for this scalar product. It is easy to see that $Q'_\mu(X; q)$ is the image of $Q_\mu(X; q)$ by the ring homomorphism
\[ p_k \mapsto (1 - q^{k})^{-1}p_k \text{ (in } \lambda\text{-ring notation, } Q'_\mu(X; q) = Q(X/(1 - q); q)). \text{ In the Schur basis,} \]
\[ Q'_\mu(X; q) = \sum_{\lambda} K_{\lambda \mu}(q)s_{\lambda}(X) \tag{5} \]

where the \( K_{\lambda \mu}(q) \) are the Kostka-Foulkes polynomials. The polynomial \( K_{\lambda \mu}(q) \) is
the generating function of a statistic \( c \) called \textit{charge} on the set \( \mathrm{Tab}(\lambda, \mu) \) of Young
\textit{tableaux of shape } \( \lambda \) and weight \( \mu \) (see also \[30, 44\], see also \[24\]).
\[ K_{\lambda \mu}(q) = \sum_{t \in \mathrm{Tab}(\lambda, \mu)} q^{c(t)}. \tag{6} \]

We shall also need the \( \tilde{Q}' \)-functions, defined by
\[ \tilde{Q}'_\mu(X; q) = \sum_{\lambda} \tilde{K}_{\lambda \mu}(q)s_{\lambda}(X) = q^{n(\mu)}Q'_\mu(X; q^{-1}). \tag{7} \]

The polynomial \( \tilde{K}_{\lambda \mu}(q) \) is the generating function of the complementary statistic
\( \tilde{c}(t) = n(\mu) - c(t) \), which is called \textit{cocharge}. The operation of \textit{cyclage} endows
\( \mathrm{Tab}(\lambda, \mu) \) with the structure of a rank poset, in which the rank of a tableau is equal
to its cocharge (see \[24\]).

When the parameter \( q \) is interpreted as the cardinality of a finite field \( \mathbb{F}_q \), it
is known that \( \tilde{K}_{\lambda \mu}(q) \) is equal to the value \( \chi^\lambda(u) \) of the unipotent character \( \chi^\lambda \) of
\( G = GL_n(\mathbb{F}_q) \) on a unipotent element \( u \) with Jordan canonical form specified by the
partition \( \mu \) (see \[36\]).

In this specialization, the coefficients
\[ \tilde{G}_{\nu \mu}(q) = \langle h_{\nu}, \tilde{Q}'_\mu \rangle \tag{8} \]
of the \( \tilde{Q}' \)-functions on the basis of monomial symmetric functions are also the values
of certain characters of \( G \) on unipotent classes. Let \( \mathcal{P}_\nu \) denote a parabolic subgroup
of type \( \nu \) of \( G \), for example the group of upper block triangular matrices with
diagonal blocks of sizes \( \nu_1, \ldots, \nu_r \), and consider the permutation representation of
\( G \) over \( \mathbb{C}[G/\mathcal{P}_\nu] \). The value \( \xi^\nu(g) \) of the character \( \xi^\nu \) of this representation on an
element \( g \in G \) is equal to the number of fixed points of \( g \) on \( G/\mathcal{P}_\nu \). Then, it can be
shown that, for a unipotent \( u \) of type \( \mu \),
\[ \xi^\nu(u) = \tilde{G}_{\nu \mu}(q). \tag{9} \]

The factor set \( G/\mathcal{P}_\nu \) can be identified with the variety \( \mathcal{F}_\nu \) of \( \nu \)-flags in \( V = \mathbb{F}_q^n \)
\[ V_{\nu_1} \subset V_{\nu_1 + \nu_2} \subset \ldots \subset V_{\nu_1 + \ldots + \nu_r} = V \]
where \( \dim V_i = i \). Thus, \( \tilde{G}_{\nu \mu}(q) \) is equal to the number of \( \mathbb{F}_q \)-rational points of the
algebraic variety \( \mathcal{F}_\nu^u \) of fixed points of \( u \) in \( \mathcal{F}_\nu \).
3 Specializations at roots of unity

As recalled in the preceding section, the Hall-Littlewood functions with parameter specialized to the cardinality \( q \) of a finite field \( \mathbb{F}_q \) provide information about the complex characters of the linear group \( GL(n, \mathbb{F}_q) \) over this field. It turns out that when the parameter is specialized to a complex root of unity, one obtains information about representations of \( GL(n, \mathbb{C}) \) (or \( U(n) \)), that is, a combinatorial decomposition of certain plethysms \cite{25, 26}. We give now a brief review of these results.

The first one is a factorization property of the functions \( Q'_\lambda(X, q) \) when \( q \) is specialized to a primitive root of unity. This is to be seen as a generalization of the fact that when \( q \) is specialized to 1 the function \( Q'_\lambda(X; q) \) reduces to \( h_\lambda(X) = \prod_i h_{\lambda_i}(X) \).

**Theorem 3.1** \cite{25} Let \( \lambda = (1^{m_1}2^{m_2} \ldots n^{m_n}) \) be a partition written multiplicatively. Set \( m_i = kq_i + r_i \) with \( 0 \leq r_i < k \), and \( \mu = (1^{n_1}2^{n_2} \ldots n^{n_n}) \). Then, \( \zeta \) being a primitive \( k \)-th root of unity,

\[
Q'_\lambda(X; \zeta) = Q'_\mu(X; \zeta) \prod_{i \geq 1} (Q'_{(ik)}(X; \zeta))^{q_i}.
\]

The functions \( Q'_{(ik)}(X; \zeta) \) appearing in the right-hand side of (10) can be expressed as plethysms.

**Theorem 3.2** \cite{25} Let \( p_k \circ h_n \) denote the plethysm of the complete function \( h_n \) by the power-sum \( p_k \), which is defined by the generating series

\[
\sum_n p_k \circ h_n(X) z^n = \prod_{x \in X} (1 - zx^k)^{-1}.
\]

Then, if \( \zeta \) is as above a primitive \( k \)-th root of unity, one has

\[
Q'_{(nk)}(X; \zeta) = (-1)^{(k-1)n} p_k \circ h_n(X).
\]

For example, with \( k = 3 \) (\( \zeta = e^{2i\pi/3} \)), we have

\[
Q'_{44433311}(X; \zeta) = Q'_{4111}(X; \zeta) Q'_333(X; \zeta) Q'_{444}(X; \zeta) = Q'_{4111}(X; \zeta) p_4 \circ h_{43}.
\]

Let \( V \) be a polynomial representation of \( GL(n, \mathbb{C}) \), with character the symmetric function \( f \). Let \( \gamma \) be the cyclic shift operator on \( V^\otimes k \), that is,

\[
\gamma(v_1 \otimes v_2 \otimes \cdots \otimes v_k) = v_2 \otimes v_3 \otimes \cdots \otimes v_k \otimes v_1.
\]

Let \( \zeta = \exp(2i\pi/k) \), and denote by \( E^{(r)} \) the eigenspace of \( \gamma \) in \( V^\otimes k \) associated with the eigenvalue \( \zeta^r \). As \( \gamma \) commutes with the action of \( GL(n) \), these eigenspaces are representations of \( GL(n) \), and their characters are given by the plethysms \( \ell_k^{(r)} \circ f \) of the character \( f \) of \( V \) by certain symmetric functions \( \ell_k^{(r)} \) that we shall now describe.

For \( k, n \in \mathbb{N} \), the Ramanujan or Von Sterneck sum \( c(k, n) \) (also denoted \( \Phi(k, n) \)) is the sum of the \( k \)-th powers of the primitive \( n \)-th roots of unity. Its value is given
by Hölder’s formula: if \((k, n) = d\) and \(n = md\), then \(c(k, n) = \mu(m)\phi(n)/\phi(m)\), where \(\mu\) is the Moebius function and \(\phi\) is the Euler totient function (see e.g. [12]).

The symmetric functions \(\ell_k^{(r)}\) are given by the formula

\[
\ell_k^{(r)} = \frac{1}{k} \sum_{d|k} c(r, d) p_d^{k/d}.
\]

These functions are the Frobenius characteristics of the representations of the symmetric group induced by irreducible representations of a transitive cyclic subgroup \([8]\). A combinatorial interpretation of the multiplicity \(\langle s_\lambda, \ell_n^{(k)} \rangle\) has been given by Kraskiewicz and Weyman \([23]\). This result is equivalent to the congruence

\[
Q_1^n(X; q) \equiv \sum_{0 \leq k \leq n-1} q^k \ell_n^{(k)} \pmod{1 - q^n}.
\]

Another proof can be found in \([4]\). Now, if \(V\) is a product of exterior powers of the fundamental representation \(C^n\)

\[
V = \Lambda^{\nu_1} C^n \otimes \Lambda^{\nu_2} C^n \otimes \cdots \otimes \Lambda^{\nu_m} C^n
\]

the character of \(E^{(r)}\) is \(\ell_k^{(r)} \circ e_\nu\), and similarly if \(V\) is a product of symmetric powers with character \(h_\nu\), the character of \(E^{(r)}\) is \(\ell_k^{(r)} \circ h_\nu\).

Given two partitions \(\lambda\) and \(\mu\), we denote by \(\lambda \lor \mu\) the partition obtained by reordering the concatenation of \(\lambda\) and \(\mu\), e.g. \((2, 2, 1) \lor (5, 2, 1) = (5, 2^3, 1^2)\). We write \(\mu^k = \mu \lor \mu \lor \cdots \lor \mu\) (\(k\) factors). If \(\mu = (\mu_1, \ldots, \mu_r)\), we set \(k\mu = (k\mu_1, \ldots, k\mu_r)\).

Taking into account Theorems 3.1 and 3.2 and following the method of \([4]\), one arrives at the following combinatorial formula for the decomposition of \(E^{(r)}\) into irreducibles:

**Theorem 3.3** \([26]\) Let \(e_i\) be the \(i\)-th elementary symmetric function, and for \(\lambda = (\lambda_1, \ldots, \lambda_m)\), \(e_\lambda = e_{\lambda_1} \cdots e_{\lambda_m}\). Then, the multiplicity \(\langle s_\mu, \ell_k^{(r)} \circ e_\lambda \rangle\) of the Schur function \(s_\mu\) in the plethysm \(\ell_k^{(r)} \circ e_\lambda\) is equal to the number of Young tableaux of shape \(\mu'\) (conjugate partition) and weight \(\lambda^k\) whose charge is congruent to \(r\) modulo \(k\).

This gives as well the plethysms with product of complete functions, since

\[
\langle s_\mu', \ell_k^{(r)} \circ e_\lambda \rangle = \begin{cases} 
\langle s_\mu, \ell_k^{(r)} \circ h_\lambda \rangle & \text{if } |\lambda| \text{ is even} \\
\langle s_\mu, \tilde{\ell}_k^{(r)} \circ h_\lambda \rangle & \text{if } |\lambda| \text{ is odd}
\end{cases}
\]

where \(\tilde{\ell}_k^{(r)} = \omega(\ell_k^{(r)}) = \ell_k^{(s)}\) with \(s = k(k-1)/2 - r\).

For example, with \(k = 4, r = 2\) and \(\lambda = (2)\),

\[
\ell_4^{(2)} \circ e_2 = s_{431} + s_{422} + s_{4111} + 2s_{3311} + 2s_{3221} + 2s_{32111} + s_{2222} + s_{22211} + 2s_{221111} + s_{2111111}.
\]

The coefficient \(\langle s_{32111}, \ell_4^{(2)} \circ e_2 \rangle = 2\) is equal to the number of tableaux of shape \((3, 2, 1, 1, 1)' = (5, 2, 1)\), weight \((2, 2, 2, 2)\) and charge \(\equiv 2\pmod{4}\). The two tableaux satisfying these conditions are
which both have charge equal to 6.

Similarly, \( \langle s_{732}, \ell_4(2^2) \rangle \) = 5 is the number of tableaux with shape (3, 3, 2, 1, 1, 1), weight (2, 2, 2, 2, 1, 1, 1) and charge \( \equiv 2 \pmod{4} \).

Another combinatorial formulation of Theorems 3.1 and 3.2 can be presented by means of the notion of \textit{ribbon tableau}, which will also provide the clue for their generalization.

\section{Ribbon tableaux}

To a partition \( \lambda \) is associated a \( k \)-core \( \lambda(k) \) and a \( k \)-quotient \( \lambda^{(k)} \). The \( k \)-core is the unique partition obtained by successively removing \( k \)-ribbons (or skew hooks) from \( \lambda \). The different possible ways of doing so can be distinguished from one another by labelling 1 the last ribbon removed, 2 the penultimate, and so on. Thus Figure 1 shows two different ways of reaching the 3-core \( \lambda(3) = (2, 1^2) \) of \( \lambda = (8, 7^2, 4, 1^5) \). These pictures represent two 3-ribbon tableaux \( T_1, T_2 \) of shape \( \lambda/\lambda(3) \) and weight \( \mu = (1^9) \).

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{ribbon_tableaux.png}
\caption{Figure 1:}
\end{figure}

To define \( k \)-ribbon tableaux of general weight and shape, we need some terminology. The \textit{initial cell} of a \( k \)-ribbon \( R \) is its rightmost and bottommost cell. Let \( \theta = \beta/\alpha \) be a skew shape, and set \( \alpha_+ = (\beta_1) \cup \alpha \), so that \( \alpha_+/\alpha \) is the horizontal strip made of the bottom cells of the columns of \( \theta \). We say that \( \theta \) is a \textit{horizontal} \( k \)-\textit{ribbon strip} of weight \( m \), if it can be tiled by \( m \) \( k \)-ribbons the initial cells of which lie in \( \alpha_+ \). (One can check that if such a tiling exists, it is unique).

Now, a \textit{k-ribbon tableau} \( T \) of shape \( \lambda/\nu \) and weight \( \mu = (\mu_1, \ldots, \mu_r) \) is defined as a chain of partitions
\[ \nu = \alpha^0 \subset \alpha^1 \subset \cdots \subset \alpha^r = \lambda \]
such that $\alpha^i/\alpha^{i-1}$ is a horizontal $k$-ribbon strip of weight $\mu_i$. Graphically, $T$ may be described by numbering each $k$-ribbon of $\alpha^i/\alpha^{i-1}$ with the number $i$. We denote by $\text{Tab}_k(\lambda/\nu, \mu)$ the set of $k$-ribbon tableaux of shape $\lambda/\nu$ and weight $\mu$, and we set

$$K_{\lambda/\nu, \mu}^{(k)} = |\text{Tab}_k(\lambda/\nu, \mu)|.$$ 

Finally we recall the definition of the $k$-sign $\epsilon_k(\lambda/\nu)$. Define the sign of a ribbon $R$ as $(-1)^{h-1}$, where $h$ is the height of $R$. The $k$-sign $\epsilon_k(\lambda/\nu)$ is the product of the signs of all the ribbons of a $k$-ribbon tableau of shape $\lambda/\nu$ (this does not depend on the particular tableau chosen, but only on the shape).

The origin of these combinatorial definitions is best understood by analyzing carefully the operation of multiplying a Schur function $s_\nu$ by a plethysm of the form $\psi^k(h_\mu) = p_k \circ h_\mu$. Equivalently, thanks to the involution $\omega$, one may rather consider a product of the type $s_\nu[p_k \circ e_\mu]$. To this end, since

$$p_k \circ e_\mu = (e_{\mu_1} \circ p_k) \cdots (e_{\mu_n} \circ p_k) = m_{k\mu_1} \cdots m_{k\mu_n},$$

one needs only to apply repeatedly the following multiplication rule due to Muir [41] (see also [44]):

$$s_\nu m_\alpha = \sum_\beta s_{\nu+\beta},$$

sum over all distinct permutations $\beta$ of $(\alpha_1, \alpha_2, \ldots, \alpha_n, 0, \ldots)$. Here the Schur functions $s_{\nu+\beta}$ are not necessarily indexed by partitions and have therefore to be put in standard form, this reduction yielding only a finite number of nonzero summands. For example,

$$s_{31} m_3 = s_{61} + s_{313} + s_{31003} = s_{61} - s_{322} + s_{314}.$$ 

Other terms such as $s_{34}$ or $s_{3103}$ reduce to 0. It is easy to deduce from this rule that the multiplicity

$$\langle s_\nu m_{k\mu}, s_\lambda \rangle$$

is nonzero iff $\lambda'/\mu'$ is a horizontal $k$-ribbon strip of weight $\mu_i$, in which case it is equal to $\epsilon_k(\lambda/\nu)$. Hence, applying $\omega$ we arrive at the expansion

$$s_\nu[p_k \circ h_\mu] = \sum_\lambda \epsilon_k(\lambda/\mu) K_{\lambda/\nu, \mu}^{(k)} s_\lambda$$

(12)

from which we deduce by 3.1, 3.2 that

$$K_{\lambda/\nu, \mu}^{(k)} = (-1)^{(k-1)|\mu|} \epsilon_k(\lambda) K_{\lambda, \mu^k}(\zeta)$$

and more generally, defining as in [21] the skew Kostka-Foulkes polynomial $K_{\lambda/\nu, \alpha}(q)$ by

$$K_{\lambda/\nu, \alpha}(q) = \langle s_{\lambda'/\mu'} Q_\alpha'(q) \rangle$$

(or as the generating functions of the charge statistic on skew tableaux of shape $\lambda/\mu$ and weight $\alpha$), we can write

$$K_{\lambda/\nu, \mu}^{(k)} = (-1)^{(k-1)|\mu|} \epsilon_k(\lambda/\nu) K_{\lambda/\nu, \mu^k}(\zeta).$$
It turns out that enumerating $k$-ribbon tableaux is equivalent to enumerating $k$-uples of ordinary Young tableaux, as shown by the correspondence to be described now. This bijection was first introduced by Stanton and White \cite{46} in the case of ribbon tableaux of right shape $\lambda$ (without $k$-core) and standard weight $\mu = (1^n)$ (see also \cite{7}). We need some additional definitions.

Let $R$ be a $k$-ribbon of a $k$-ribbon tableau. $R$ contains a unique cell with coordinates $(x, y)$ such that $y - x \equiv 0 \pmod{k}$. We decide to write in this cell the number attached to $R$, and we define the type $i \in \{0, 1, \ldots, k - 1\}$ of $R$ as the distance between this cell and the initial cell of $R$. For example, the 3-ribbons of $T_1$ are divided up into three classes (see Fig. II):

- 4, 6, 8, of type 0;
- 1, 2, 7, 9, of type 1;
- 3, 5, of type 2.

Define the diagonals of a $k$-ribbon tableau as the sequences of integers read along the straight lines $D_i : y - x = ki$. Thus $T_1$ has the sequence of diagonals

$$((8), (4), (2, 3, 6), (1, 5, 9), (7)) .$$

This definition applies in particular to 1-ribbon tableaux, i.e. ordinary Young tableaux. It is obvious that a Young tableau is uniquely determined by its sequence of diagonals. Hence, we can associate to a given $k$-ribbon tableau $T$ of shape $\lambda/\nu$ a $k$-uple $(t_0, t_1, \ldots, t_{k-1})$ of Young tableaux defined as follows; the diagonals of $t_i$ are obtained by erasing in the diagonals of $T$ the labels of all the ribbons of type $\neq i$. For instance, if $T = T_1$ the first ribbon tableau of Figure II, the sequence of diagonals of $t_1$ is $((2), (1, 9), (7))$, and

$$t_1 = \begin{array}{cc} 2 & 9 \\ 1 & 7 \end{array}$$

The complete triple $(t_0, t_1, t_2)$ of Young tableaux associated to $T_1$ is

$$\tau^1 = \left( \begin{array}{cc} 8 & 4 \\ 6 & 1 \end{array} , \begin{array}{cc} 2 & 9 \\ 1 & 7 \end{array} , \begin{array}{cc} 3 & 5 \end{array} \right)$$

whereas that corresponding to $T_2$ is

$$\tau^2 = \left( \begin{array}{cc} 3 & 1 \\ 8 & 4 \end{array} , \begin{array}{cc} 6 & 9 \\ 4 & 5 \end{array} , \begin{array}{cc} 2 & 7 \end{array} \right)$$

One can show that if $\nu = \lambda^{(k)}$, the $k$-core of $\lambda$, the $k$-uple of shapes $(\lambda^0, \lambda^1, \ldots, \lambda^{k-1})$ of $(t_0, t_1, \ldots, t_{k-1})$ depends only on the shape $\lambda$ of $T$, and is equal to the $k$-quotient $\lambda^{(k)}$ of $\lambda$. Moreover the correspondence $T \rightarrow (t_0, t_1, \ldots, t_{k-1})$ establishes a bijection between the set of $k$-ribbon tableaux of shape $\lambda/\lambda^{(k)}$ and weight $\mu$, and the set of
$k$-uples of Young tableaux of shapes $(\lambda^0, \ldots, \lambda^{k-1})$ and weights $(\mu^0, \ldots, \mu^{k-1})$ with $\mu_i = \sum_j \mu^j_i$. (See [13] or [1] for a proof in the case when $\lambda^{(k)} = (0)$ and $\mu = (1^n)$).

For example, keeping $\lambda = (8, 7^2, 4, 1^5)$, the triple

$$\tau = \left(\begin{array}{c} 4 \\ 3 3 \\ 2 4 \\ 1 3 \\ 2 3 \end{array}\right)$$

with weights $((0, 0, 2, 1), (1, 1, 1, 1), (0, 1, 1, 0))$ corresponds to the 3-ribbon tableau $T$

of weight $\mu = (1, 2, 4, 2)$.

As before, the significance of this combinatorial construction becomes clearer once interpreted in terms of symmetric functions. Recall the definition of $\phi_k$, the adjoint of the linear operator $\psi^k : F \mapsto p_k \circ F$ acting on the space of symmetric functions. In other words, $\phi_k$ is characterized by

$$\langle \phi_k(F) , G \rangle = \langle F , p_k \circ G \rangle , \quad F, G \in \text{Sym} .$$

Littlewood has shown [13] that if $\lambda$ is a partition whose $k$-core $\lambda^{(k)}$ is null, then

$$\phi_k(s_{\lambda}) = \epsilon_k(\lambda) s_{\lambda^0} s_{\lambda^1} \cdots s_{\lambda^{k-1}} \quad (13)$$

where $\lambda^{(k)} = (\lambda^0, \ldots, \lambda^{k-1})$ is the $k$-quotient. Therefore,

$$K_{\lambda\mu}^{(k)} = \epsilon_k(\lambda) \langle p_k \circ h_\mu , s_{\lambda} \rangle = \epsilon_k(\lambda) \langle \phi_k(s_{\lambda}) , h_\mu \rangle = \langle s_{\lambda^0} s_{\lambda^1} \cdots s_{\lambda^{k-1}} , h_\mu \rangle$$

is the multiplicity of the weight $\mu$ in the product of Schur functions $s_{\lambda^0} \cdots s_{\lambda^{k-1}}$, that is, is equal to the number of $k$-uples of Young tableaux of shapes $(\lambda^0, \ldots, \lambda^{k-1})$ and weights $(\mu^0, \ldots, \mu^{k-1})$ with $\mu_i = \sum_j \mu^j_i$. Thus, the bijection described above gives a combinatorial proof of (13).

More generally, if $\lambda$ is replaced by a skew partition $\lambda/\nu$, (13) becomes [17]

$$\phi_k(s_{\lambda/\nu}) = \epsilon_k(\lambda/\nu) s_{\lambda^0/\nu^0} s_{\lambda^1/\nu^1} \cdots s_{\lambda^{k-1}/\nu^{k-1}}$$

if $\lambda^{(k)} = \nu^{(k)}$, and 0 otherwise. This can also be deduced from the previous combinatorial correspondence, but we shall not go into further details.

Returning to Kostka polynomials, we may summarize this discussion by stating Theorems [3.1] and [3.2] in the following way:
Theorem 4.1 Let \( \lambda \) and \( \nu \) be partitions and set \( \nu = \mu^k \vee \alpha \) with \( m_i(\alpha) < k \). Denoting by \( \zeta \) a primitive \( k \)th root of unity, one has
\[
K_{\lambda, \nu}(\zeta) = (-1)^{(k-1)|\mu|} \sum_{\beta} \epsilon_k(\lambda/\beta) R^{(k)}_{\lambda/\beta, \mu} K_{\beta, \alpha}(\zeta) .
\] (14)

Example 4.2 We take \( \lambda = (4^2, 3) \), \( \nu = (2^2, 1^7) \) and \( k = 3 \) (\( \zeta = e^{2i\pi/3} \)). In this case, \( \nu = \mu^k \vee \alpha \) with \( \mu = (1^2) \) and \( \alpha = (2^2, 1) \). The summands of (14) are parametrized by the 3-ribbon tableaux of external shape \( \lambda \) and weight \( \mu \). Here we have three such tableaux:

\[
\begin{array}{cccc}
\text{2} & & & \\
\text{1} & & & \\
\hline
\end{array}
\quad
\begin{array}{cccc}
\text{2} & & & \\
\text{1} & & & \\
\hline
\end{array}
\quad
\begin{array}{cccc}
\text{2} & & & \\
\hline
\end{array}
\]

so that
\[
K_{443, 22111111}(\zeta) = 2K_{41, 221}(\zeta) - K_{32, 221}(\zeta) = 2(\zeta^2 + \zeta^3) - (\zeta + \zeta^2) = 2\zeta^2 + 3 .
\]

When \( |\alpha| \leq |\lambda(\beta)| \), (14) becomes simpler. For if \( |\alpha| < |\lambda(\beta)| \) then \( K_{\lambda, \nu}(\zeta) = 0 \), and otherwise the sum reduces to one single term
\[
K_{\lambda, \nu}(\zeta) = (-1)^{(k-1)|\mu|} \epsilon_k(\lambda/\lambda(\beta)) R^{(k)}_{\lambda/\lambda(\beta), \mu} K_{\lambda(\beta), \alpha}(\zeta) .
\]

In particular, for \( \nu = (1^n) \), one recovers the expression of \( K_{\lambda, (1^n)}(\zeta) \) given by Morris and Sultana [40].

Finally, let us observe that the notion of \( k \)-sign of a partition can be lifted to a statistic on ribbon tableaux, which for technical reasons that will become transparent later, takes values in \( \mathbb{N} + \frac{1}{2}\mathbb{N} \), and will be called spin.

Let \( R \) be a \( k \)-ribbon, \( h(R) \) its height and \( w(R) \) its width.

\[
\text{h}(R)
\]
\[
\text{w}(R)
\]

The spin of \( R \), denoted by \( s(R) \), is defined as
\[
s(R) = \frac{h(R) - 1}{2} \quad (15)
\]
and the spin of a ribbon tableau \( T \) is by definition the sum of the spins of its ribbons. For example, the ribbon tableau

12
has a spin equal to 6.

The \( k \)-sign of a partition \( \lambda \) is thus equal to \((-1)^{2s(T)}\), for any ribbon tableau \( T \) of shape \( \lambda \). For example, we can rewrite the particular case \( \nu = (0) \) of formula (12) as

\[
\psi^k(h_\mu) = p_k \circ h_\mu = \sum_{T \in \text{Tab}_k(\cdot, \mu)} (-1)^{2s(T)} s_T
\]

where \( \text{Tab}_k(\cdot, \mu) \) is the set of \( k \)-ribbon tableaux of weight \( \mu \), and \( s_T = s_\lambda \) if \( \lambda \) is the shape of \( T \). We shall see in the next section that this formula leads to a simple construction of a basis of highest weight vectors in the Fock space representation of the quantum affine algebra \( \widehat{U}_q(sl_n) \).

5  The Fock representation of \( \widehat{U}_q(sl_n) \)

The affine Lie algebra \( \widehat{sl}_n = A_n \) has a natural action on the space \( \text{Sym} \) of symmetric functions, called the bosonic Fock space representation. This representation is equivalent to the infinite wedge, or fermionic Fock space representation, and the isomorphism can be realized by means of vertex operators (see e.g. [13]).

Let us recall briefly the fermionic version. Let \( V \) be the vector space \( \mathbb{C}^Z \) and \( (u_i)_{i \in Z} \) be its canonical basis. The fermionic Fock space \( \Lambda^\infty V \) is defined as the vector space spanned by the infinite exterior products

\[
u_i \wedge \nu_2 \wedge \cdots \wedge \nu_n \wedge \cdots \]

satisfying \( i_1 > i_2 > i_3 > \cdots > i_n > \cdots \) and \( i_k - i_{k+1} = 1 \) for \( k > 0 \). The wedge product is as usual alternating, and linear in each of its factors. We denote by \( \mathcal{F} \) the subspace of \( \Lambda^\infty V \) spanned by the elements such that \( i_k = -k + 1 \) for \( k > 0 \) (usually this subspace is denoted by \( \mathcal{F}^{(0)} \), but as we shall not need the other sectors \( \mathcal{F}^{(m)} \), we drop the superscript).

The Lie algebra \( \mathfrak{gl}_\infty \) of \( Z \times Z \) complex matrices \( A = (a_{ij}) \) with finitely many nonzero entries acts on \( \Lambda^\infty V \) by

\[
A \cdot \nu_{i_1} \wedge \nu_{i_2} \wedge \cdots = (A\nu_{i_1}) \wedge \nu_{i_2} \wedge \cdots + \nu_{i_1} \wedge (A\nu_{i_2}) \wedge \cdots + \cdots
\]

the sum having only a finite number of nonzero terms.

Let \( E_{ij} \) be the infinite matrix \( (E_{ij})_{rs} = \delta_{ir}\delta_{js} \). The subalgebra \( \mathfrak{sl}_\infty \) of \( \mathfrak{gl}_\infty \) constituted by the matrices with zero trace has for Chevalley generators \( e_i^\infty = E_{i,i+1} \), \( f_i^\infty = E_{i+1,i} \) and \( h_i = E_{i,i} - E_{i+1,i+1} \), \( i \in Z \). The infinite sums

\[
e_i = \sum_{j \equiv i \mod n} e_j^\infty, \quad f_i = \sum_{j \equiv i \mod n} f_j^\infty, \quad h_i = \sum_{j \equiv i \mod n} h_j^\infty
\]
do not belong to $\mathfrak{gl}_\infty$, but they have a well-defined action on $\wedge^\infty V$, and it can be checked that they generate a representation of $\widehat{\mathfrak{sl}}'_n$ with central charge $c = 1$. The remaining generator $D$ of $\widehat{\mathfrak{sl}}_n = \widehat{\mathfrak{sl}}'_n \oplus C D$ can be implemented by

$$D := - \sum_{i \in \mathbb{Z}} \left[ i \over n \right] (E_{ii} - \theta(-i - 1)),$$

where $\theta(x) = 1$ for $x \geq 0$ and $\theta(x) = 0$ otherwise (cf. [3]).

The basis vectors of $\mathcal{F}$ can be labelled by partitions, by setting

$$|\lambda\rangle = u_{\lambda_1} \wedge u_{\lambda_2} \wedge u_{\lambda_3-1} \wedge \cdots .$$

With this indexation, the action of the Chevalley generators of $\widehat{\mathfrak{sl}}_n$ can be described as follows [3].

To each node $(i, j)$ of a Young diagram, one can associate its residue $\rho_{i,j} = j - i \mod n \in \{0, \ldots, n - 1\}$. Then,

$$e_r |\lambda\rangle = \sum |\mu\rangle , \quad f_r |\lambda\rangle = \sum |\nu\rangle$$

where $\mu$ (resp. $\nu$) runs over all diagrams obtained from $\lambda$ by removing (resp. adding) a node of residue $r$.

In this picture, one can observe that $e_r$ and $f_r$ are exactly the $r$-restricting and $r$-inducing operators introduced by G. de B. Robinson in the context of the modular representation theory of the symmetric group [43].

The natural way of interpreting the basis vectors $|\lambda\rangle$ as symmetric functions is to put $|\lambda\rangle = s_\lambda$. This is imposed by the boson-fermion correspondence, and it is also compatible with the modular representation interpretation.

In this realization, it can be shown that the image $U(\widehat{\mathfrak{sl}}_n) |0\rangle$ of the constant $|0\rangle = s_0 = 1$, which is the basic representation $M(\Lambda_0)$, is equal to the subalgebra

$$\mathcal{T}^{(n)} = \mathbb{C}[p_i \mid i \not\equiv 0 \mod n]$$

generated by the power-sums $p_i$ such that $n \not\mid i$.

The bosonic operators

$$b_k : f \mapsto D_{p_{kn}} f = kn \frac{\partial}{\partial p_{kn}} f \quad \text{and} \quad b_{-k} : f \mapsto p_{kn} f \quad (k \geq 1)$$

commute with the action of $\widehat{\mathfrak{sl}}_n$. They generate a Heisenberg algebra $\mathcal{H}$, and the irreducible $\mathcal{H}$-module $U(\mathcal{H}) |0\rangle$ is exactly the space $\mathcal{S}^{(n)}$ of highest weight vectors of the Fock space, viewed as an $\widehat{\mathfrak{sl}}_n$-module. Thus, these highest weight vectors are exactly the plethysms $\psi^n(f), f \in \text{Sym}$. Natural bases of $\mathcal{S}^{(n)}$ are therefore

$$\psi^n(p_\mu) = p_{n\mu}, \psi^n(s_\mu) \text{ or } \psi^n(h_\mu).$$

We know from Section [4] that this last one admits a simple combinatorial description in terms of ribbon tableaux:

$$\psi^n(h_\mu) = \sum_{\lambda} \epsilon_n(\lambda/\mu) K^{(n)}_{\lambda\mu} s_\lambda = \sum_{T \in \text{Tab}_n(\cdot, \mu)} (-1)^{2s(T)} s_T .$$

(18)
This formula is especially meaningful in the quantized version, that we shall now describe.

We first recall the definition of $U_q(\hat{\mathfrak{sl}}_n)$ (cf. 
and references therein). Let $\mathfrak{h}$ be a $(n+1)$-dimensional vector space over $\mathbb{Q}$ with basis $\{h_0, h_1, \ldots, h_{n-1}, D\}$. We denote by $\{\Lambda_0, \Lambda_1, \ldots, \Lambda_{n-1}, \delta\}$ the dual basis of $\mathfrak{h}^*$, that is,

$$
\langle \Lambda_i, h_j \rangle = \delta_{ij}, \quad \langle \Lambda_i, D \rangle = 0, \quad \langle \delta, h_i \rangle = 0, \quad \langle \delta, D \rangle = 1,
$$

and we set $\alpha_i = 2\Lambda_i - \Lambda_{i-1} - \Lambda_{i+1} + \delta_i \delta$ for $i = 0, 1, \ldots, n-1$. In these formulas it is understood that $\Lambda_n = 0$ and $\Lambda_{-1} = \Lambda_{n-1}$. The $n \times n$ matrix $[[\alpha_i, h_j]]$ is the generalized Cartan matrix associated to $\hat{\mathfrak{sl}}_n$. The weight lattice is $P = \bigoplus_{i=0}^{n-1} \mathbb{Z} \Lambda_i \oplus \mathbb{Z} \delta$, its dual is $P^\vee = \bigoplus_{i=0}^{n-1} \mathbb{Z} h_i \oplus \mathbb{Z} D$, and the root lattice is $Q = \bigoplus_{i=0}^{n-1} \mathbb{Z} \alpha_i$. One defines $U_q(\hat{\mathfrak{sl}}_n)$ as the associative algebra with 1 over $\mathbb{Q}(q)$ generated by the symbols $e_i, f_i, 0 \leq i \leq n-1$, and $q^h, h \in P^\vee$, subject to the relations

$$
q^h q^{h'} = q^{h+h'}, \quad q^0 = 1,
$$

$$
q^h e_j q^{-h} = q^{\langle \alpha_j, h \rangle} e_j,
$$

$$
q^h f_j q^{-h} = q^{-\langle \alpha_j, h \rangle} f_j,
$$

$$
[e_i, f_j] = \delta_{ij} \frac{q^{h_i} - q^{-h_i}}{q - q^{-1}},
$$

\[
\sum_{k=0}^{1-\langle \alpha_i, h_j \rangle} (-1)^k \left[ 1 - \langle \alpha_i, h_j \rangle \right] e_i^{1-\langle \alpha_i, h_j \rangle - k} e_j e_i^k = 0 \quad (i \neq j),
\]

\[
\sum_{k=0}^{1-\langle \alpha_i, h_j \rangle} (-1)^k \left[ 1 - \langle \alpha_i, h_j \rangle \right] f_i^{1-\langle \alpha_i, h_j \rangle - k} f_j f_i^k = 0 \quad (i \neq j).
\]

Here the $q$-integers, $q$-factorials and $q$-binomial coefficients are the symmetric ones:

$$
[k] = \frac{q^k - q^{-k}}{q - q^{-1}}, \quad [k]! = [k] [k-1] \cdots [1], \quad \binom{m}{k} = \frac{[m]!}{[m-k]! [k]!}.
$$

We now recall some definitions relative to $U_q(\hat{\mathfrak{sl}}_n)$-modules. Let $M$ be a $U_q(\hat{\mathfrak{sl}}_n)$-module and $\Lambda \in P$ a weight. The subspace

$$
M_\Lambda = \{v \in M \mid q^h v = q^{\langle \Lambda, h \rangle} v, \ h \in P^\vee\}
$$

is called the weight space of weight $\Lambda$ of $M$ and its elements are called the weight vectors of weight $\Lambda$. The module $M$ is said to be integrable if

(i) \quad $M = \bigoplus_{\Lambda \in P} M_\Lambda$,

(ii) \quad $\dim M_\Lambda < \infty$ for $\Lambda \in P$,

(iii) \quad for $i = 0, 1, \ldots, n-1$, $M$ decomposes into a direct sum of finite dimensional $U_i$-modules, where $U_i$ denotes the subalgebra of $U_q(\hat{\mathfrak{sl}}_n)$ generated by $e_i, f_i, q^{h_i}, q^{-h_i}$. 

15
A highest weight vector \( v \in M \) is a vector annihilated by all raising operators \( e_i \). The module \( M \) is said to be a highest weight module if there exists a highest weight vector \( v \) such that \( M = U_q(\hat{\mathfrak{sl}}_n) v \). The weight of \( v \) is called the highest weight of \( M \).

By the representation theory of \( U_q(\hat{\mathfrak{sl}}_n) \), there exists for each dominant integral weight \( \Lambda \) (i.e. \( \langle \Lambda, h_i \rangle \in \mathbb{Z}_+ \) for \( i = 0, 1, \ldots, n-1 \)) a unique integrable highest weight module \( M(\Lambda) \) with highest weight \( \Lambda \).

A \( q \)-analog of the Fock representation of \( \hat{\mathfrak{sl}}_n \) can be realized in the \( \mathbb{Q}(q) \)-vector space \( \mathcal{F} \) spanned by all partitions:

\[
\mathcal{F} = \bigoplus_{\lambda \in \mathbb{P}} \mathbb{Q}(q) |\lambda\rangle
\]

the action being defined in combinatorial terms.

Let us say that a point \((a, b)\) of \( \mathbb{Z}_+ \times \mathbb{Z}_+ \) is an indent \( i \)-node of a Young diagram \( \lambda \) if a box of residue \( i = a - b \mod n \) can be added to \( \lambda \) at position \((a, b)\), in such a way that the new diagram still corresponds to a partition. Similarly, a node of \( \lambda \) of residue \( i \) which can be removed will be called a removable \( i \)-node.

Let \( i \in \{0, 1, \ldots, n-1\} \) and let \( \lambda, \nu \) be two partitions such that \( \nu \) is obtained from \( \lambda \) by filling an indent \( i \)-node \( \gamma \) We set:

\[
N^i_i(\lambda) = \#\{ \text{indent } i\text{-nodes of } \lambda \} - \#\{ \text{removable } i\text{-nodes of } \lambda \},
\]

\[
N^l_i(\lambda, \nu) = \#\{ \text{indent } i\text{-nodes of } \lambda \text{ situated to the left of } \gamma \} - \#\{ \text{removable } i\text{-nodes of } \lambda \text{ situated to the left of } \gamma \},
\]

\[
N^r_i(\lambda, \nu) = \#\{ \text{indent } i\text{-nodes of } \lambda \text{ situated to the right of } \gamma \} - \#\{ \text{removable } i\text{-nodes of } \lambda \text{ situated to the right of } \gamma \},
\]

\[
N^0(\lambda) = \#\{ 0\text{-nodes of } \lambda \}.
\]

The following result is due to Hayashi [11], and the formulation that we use has been given by Misra and Miwa [38] (with a slight change in the conventions, that is conjugation of partitions and \( q \to 1/q \)).

**Theorem 5.1** The algebra \( U_q(\hat{\mathfrak{sl}}_n) \) acts on \( \mathcal{F} \) by
\[q^h |\lambda\rangle = q^{N(\lambda)} |\lambda\rangle,\]
\[q^D |\lambda\rangle = q^{-N(\lambda)} |\lambda\rangle,\]
\[f_i|\lambda\rangle = \sum_\nu q^{N(\lambda,\nu)} |\nu\rangle, \text{ sum over all partitions } \nu \text{ such that } \nu/\lambda \text{ is a } i\text{-node},\]
\[e_i|\nu\rangle = \sum_\lambda q^{-N(\lambda,\nu)} |\lambda\rangle, \text{ sum over all partitions } \lambda \text{ such that } \nu/\lambda \text{ is a } i\text{-node}.\]

It is easy to see that \(\mathcal{F}\) is an integrable \(U_q(\widehat{\mathfrak{sl}}_n)\)-module. It is not irreducible. Actually it decomposes as
\[\mathcal{F} \cong \bigoplus_{k \geq 0} M(\Lambda_0 - k\delta)^{\oplus p(k)}.\]

Obviously, the empty partition \(|0\rangle\) is a highest weight vector of weight \(\Lambda_0\). The submodule \(U_q(\widehat{\mathfrak{sl}}_n)|0\rangle\) is isomorphic to \(M(\Lambda_0)\), also called the basic representation of \(U_q(\widehat{\mathfrak{sl}}_n)\). Again, one can identify \(\mathcal{F}\) with \(\text{Sym}\) (with coefficients in \(\mathbb{Q}(q)\)) and interpret \(|\lambda\rangle\) as \(s_\lambda\). Then, a natural \(q\)-analog of (18) gives a basis of highest weight vectors for \(U_q(\widehat{\mathfrak{sl}}_n)\) in \(\mathcal{F}\):

**Proposition 5.2** Define a linear operator \(\psi^n_q\) on \(\text{Sym}\) by
\[\psi^n_q(h_\mu) = \sum_{T \in \text{Tab}_n(\cdot,\mu)} (-q)^{-2s(T)} s_T.\]

Then, its image \(\psi^n_q(\text{Sym})\) is the space \(S^{(n)}\) of highest weight vectors of \(U_q(\widehat{\mathfrak{sl}}_n)\) in \(\text{Sym}\).

**Example 5.3** The plethysm \(\psi^2(h_{21})\) is given by the following domino tableaux

\[
\begin{array}{c}
1 & 1 & 2 \\
1 & 1 \\
2 \\
1 & 1
\end{array}
\quad
\begin{array}{c}
1 & 1 & 2 \\
1 & 1 \\
2 \\
1 & 1
\end{array}
\quad
\begin{array}{c}
1 & 2 \\
1 & 2 \\
1 & 1 \\
2 & 1 & 1
\end{array}
\]

and the corresponding highest weight vector of \(U_q(\widehat{\mathfrak{sl}}_2)\) is
\[\psi^2_q(h_{21}) = s_6 - q^{-1}s_{51} + (1 + q^{-2})s_{42} - q^{-1}s_{411} - (q^{-1} + q^{-3})s_{33} + q^{-2}s_{3111} + q^{-2}s_{222} - q^{-3}s_{2211}\]

The proposition is a consequence of the following more precise statement.
Theorem 5.4 Let $U_k$, $V_k$ ($k \geq 1$) be the linear operators defined by

$$V_k s_\lambda = \sum_\mu \left( \sum_{T \in \text{Tab}_n(\mu/\lambda(k))} (-q)^{-2s(T)} \right) s_\mu ,$$

$$U_k s_\lambda = \sum_\nu \left( \sum_{T \in \text{Tab}_n(\lambda/\nu(k))} (-q)^{-2s(T)} \right) s_\nu ,$$

so that $V_k$ is a $q$-analog of $f \mapsto \psi^n(h_k)f$, and $U_k$ is its adjoint. Then, $U_k$ and $V_k$ commute with the action of $U_q(\widehat{\mathfrak{sl}_n})$. In particular, each $\psi^n_q(h_\mu) = V_{\mu_r} \cdots V_{\mu_1}|0\rangle$ is a highest weight vector.

This result can be obtained by a direct verification, using formula (12). However, a more illuminating approach comes from comparison with a recent construction of Stern [17] and Kashiwara, Miwa and Stern [16]. These authors construct the $q$-analog of the Fock representation by means of a $q$-deformation of the wedge product, defined in terms of an action of the affine Hecke algebra $\widehat{H}_N(q^{-2})$ on a tensor product $V(z)^{\otimes n}$ of evaluation modules.

Here, $V(z)$ is $C(Z)$ realized as

$$\left( \bigoplus_{i=1}^n C v_i \right) \otimes C[z, z^{-1}] ,$$

where $z^i v_j$ is identified with $u_{j-i}$, endowed with an appropriate $q$-analog of the action of $\mathfrak{sl}_n$ on $V$.

Writing $z^r_1 v_{m_1} \otimes \cdots \otimes z^r_N v_{m_N}$ as $v_m z^r = v_{m_1} \otimes \cdots \otimes v_{m_N} \cdot z^r_1 \cdots z^r_N$, the right action of $\widehat{H}_N(q^{-2})$ on $V(z)^{\otimes n}$ is described by the following formulas [17, 16]:

$$y_i \text{ acts as } z_i^{-1} \quad \text{and}$$

$$(v_m \cdot z^r)T_i = \begin{cases} -q^{-1} v_{m_\sigma i} \cdot \sigma_i(z^r) + (q^{-2} - 1)v_m \cdot \partial_i(z_i z^r) & \text{if } m_i < m_{i+1} \\ -v_m \cdot \sigma_i(z^r) + (q^{-2} - 1)v_m \cdot z_i \partial_i(z^r) & \text{if } m_i = m_{i+1} \\ -q^{-1} v_{m_\sigma i} \cdot \sigma_i(z^r) + (q^{-2} - 1)v_m \cdot z_i \partial_i(z^r) & \text{if } m_i > m_{i+1} \end{cases} \quad (19)$$

where $m\sigma = (m_{\sigma(1)}, \ldots, m_{\sigma(N)})$ and $\partial_i$ is the divided difference operator $f(z) \mapsto (f - \sigma_i(f))/(z_i - z_{i+1})$. This action can be regarded as a generalization of the one given in [3], which would correspond to the degenerate case $n = 1$.

The important point is that this action commutes with $U_q(\widehat{\mathfrak{sl}_n})$. Let $A^{(N)} = \sum_{\sigma \in S_N} T_\sigma$. This is a $q$-analog of the total antisymmetrizer of $S_N$, since signs have been incorporated in formulas (19) in such a way that $T_\sigma$ acts as a $q$-analog of $-\sigma_i$. Kashiwara, Miwa and Stern define then the $q$-exterior powers by $\Lambda_q^N V(z) = V(z)/\ker A^{(N)}$, and denote by $u_{i_1} \wedge_q \cdots \wedge_q u_{i_N}$ the image of $u_{i_1} \otimes \cdots \otimes u_{i_N}$ in the quotient. A basis of $\Lambda_q^N V(z)$ is formed by the normally ordered products $u_{i_1} \wedge_q \cdots \wedge_q u_{i_N}$, where $i_1 > i_2 > \ldots > i_N$, and any $q$-wedge product can be expressed on this basis, by means of the following relations iteratively applied to consecutive factors. Suppose that $\ell < m$ and that $\ell - m \mod n = i$. Set $t = q^{-1}$. Then,
— if \( i = 0 \) then \( u_{\ell} \wedge_q u_m = -u_m \wedge_q u_{\ell} \)
— otherwise, \( u_{\ell} \wedge_q u_m = -t u_m \wedge_q u_{\ell} + (t^2 - 1)(u_{m-i} \wedge_q u_{\ell+i} - t u_{m-n} \wedge_q u_{m+n} + \cdots) \)

where the only terms to be taken into account in this last expression are the normally ordered ones.

There is then a well-defined action of \( U_q(\hat{\mathfrak{sl}}_n) \) on the “thermodynamic limit” \( \mathcal{F}_q = \Lambda^\infty_q V(z) = \lim_{N \to \infty} \Lambda^N_q V(z) \), which provides another realization of the \( q \)-Fock representation.

The affine Hecke algebra does not act anymore on \( \bigwedge^N_q V(z) \), but its center does. This center is generated by the power sums

\[
p_k(Y) = \sum_{i=1}^N y_i^k \quad k = \pm 1, \pm 2, \ldots
\]

and at the thermodynamic limit, the operators

\[
B_k = \sum_{i=1}^\infty y_i^{-k}
\]

are shown in [16] to generate an action of a Heisenberg algebra on \( \mathcal{F}_q \), with

\[
[B_k, B_\ell] = k \frac{1 - q^{2nk}}{1 - q^{2k}} \cdot \delta_{k,-\ell}.
\]

(20)

If one interprets the infinite \( q \)-wedges as Schur functions, by the same rule as in the classical case, one sees that \( B_{-k} \ (k \geq 1) \) is a \( q \)-analogue of the multiplication operator \( f \mapsto p_{nk} f \), and that \( B_k \) corresponds to its adjoint \( D_{p_{nk}} \).

To connect this construction with the preceding one, take for generators of the center of the affine Hecke algebra the elementary symmetric functions in the \( y_i \) and \( y_i^{-1} \) instead of the power sums, and define operators on \( \mathcal{F}_q \) by

\[
\tilde{U}_k = e_k(y_1, y_2, \ldots), \quad \tilde{V}_k = e_k(y_1^{-1}, y_2^{-1}, \ldots).
\]

These operators commute with \( U_q(\hat{\mathfrak{sl}}_n) \), and their action can be described in terms of ribbon tableau:

**Lemma 5.5**

\[
\tilde{U}_k |\lambda\rangle = \sum_{\nu} \left( \sum_{T \in \text{Tab}_n(\lambda' / \nu', (k))} (-q)^{-2s(T)} \right) |\nu\rangle \quad (21)
\]

\[
\tilde{V}_k |\lambda\rangle = \sum_{\mu} \left( \sum_{T \in \text{Tab}_n(\mu' / \lambda', (k))} (-q)^{-2s(T)} \right) |\mu\rangle.
\]

(22)

**Proof** — It is sufficient to work with \( \Lambda^N_q V(z) \) for \( N \) sufficiently large. Then,

\[
\tilde{V}_k u_{i_1} \wedge_q \cdots \wedge_q u_{i_N} = \sum_j u_{i_1+j_1} \wedge_q \cdots \wedge_q u_{i_N+j_N}
\]
where \( J \) runs through the distinct permutations of the integer vector \((0^N-k_\mu k)\). The only reorderings needed to express a term of this sum in standard form are due to the appearance of factors of the form \( u_i \wedge q u_{j+n} \) with \( j+n > i > j \). In this case, \( u_i \wedge q u_{j+n} = -tu_{j+n} \wedge q u_i \) since the other terms \((t^2-1)(u_{j+n-a} \wedge q u_{i+a} - tu_j \wedge q u_{i+n} + \cdots)\) vanish, the residue \( a = j + n - i \mod n \) being actually equal to \( j + n - i \). The first case of the straightening rule is never encountered because \( j + n - i = 0 \mod n \) would imply \( i - j = bn \) with \( b > 0 \), so that \( j + n \neq i \).

Thus,

\[
u_{i_1+j_1} \wedge q \cdots \wedge q u_{i_N+j_N} = (-t)^{\ell(\sigma)} u_{i_{\sigma(1)}+j_{\sigma(1)}} \wedge q \cdots \wedge q u_{i_{\sigma(N)}+j_{\sigma(N)}},\]

where \( \sigma \) is the shortest permutation such that the result is normally ordered. In view of the remarks in Section 4, this gives the result for \( \tilde{V}_k \). The argument for \( \tilde{U}_k \) is similar.

**Corollary 5.6** The operators \( U_k, V_k \) of Theorem 5.4 act on \( \mathcal{F}_q \) as \( h_k(y_1, y_2, \ldots) \) and \( h_k(y_1^{-1}, y_2^{-1}, \ldots) \) respectively. In particular, \([U_i, U_j] = [V_i, V_j] = 0\).

### 6 \( H \)-functions

Let \( \lambda \) be a partition without \( k \)-core, and with \( k \)-quotient \((\lambda^0, \ldots, \lambda^{k-1})\). For a ribbon tableau \( T \) of weight \( \mu \), let \( x^T = x_1^{\mu_1} x_2^{\mu_2} \cdots x_r^{\mu_r} \). Then, the correspondence between \( k \)-ribbon tableaux and \( k \)-tuples of ordinary tableaux shows that the generating function

\[
\mathcal{G}_\lambda^{(k)} = \sum_{T \in \text{Tab}_k(\lambda, \cdots)} x^T = \prod_{i=0}^{k-1} \sum_{t_i \in \text{Tab}(\lambda^i, \cdots)} x^{t_i} = \prod_{i=0}^{k-1} s_{\lambda^i} \quad (23)
\]

is a product of Schur functions. Introducing in this equation an appropriate statistic on ribbon tableaux, one can therefore obtain \( q \)-analogues of products of Schur functions. The statistic called \textit{cospin}, described below, leads to \( q \)-analogues with interesting properties.

For a partition \( \lambda \) without \( k \)-core, let

\[
s_k^*(\lambda) = \max\{s(T) \mid T \in \text{Tab}_k(\lambda, \cdots)\}. \quad (24)
\]

The \textit{cospin} \( \bar{s}(T) \) of a \( k \)-ribbon tableau \( T \) of shape \( \lambda \) is then

\[
\bar{s}(T) = s_k^*(\lambda) - s(T). \quad (25)
\]

Although \( s(T) \) can be a half-integer, it is easily seen that \( \bar{s}(T) \) is always an integer. Also, there is one important case where \( s(T) \) is an integer. This is when the shape \( \lambda \) of \( T \) is of the form \( k\mu = (k\mu_1, k\mu_2, \ldots, k\mu_r) \). In this case, the partitions constituting the \( k \)-quotient of \( \lambda \) are formed by parts of \( \mu \), grouped according to the class modulo \( k \) of their indices. More precisely, \( \lambda^i = \{\mu_r \mid r \equiv -i \mod k\} \).

We can now define three families of polynomials
\[
\tilde{G}_\lambda^{(k)}(X; q) = \sum_{T \in \text{Tab}_k(\lambda, \cdot)} q^{s(T)} x^T
\]  
(26)

\[
\tilde{H}_\mu^{(k)}(X; q) = \sum_{T \in \text{Tab}_k(k\mu, \cdot)} q^{s(T)} x^T = \tilde{G}_{k\mu}^{(k)}(X; q)
\]  
(27)

\[
H_\mu^{(k)}(X; q) = \sum_{T \in \text{Tab}_k(k\mu, \cdot)} q^{s(T)} x^T = q^{s(k\mu)} \tilde{H}_{\mu}^{(k)}(X; 1/q).
\]  
(28)

The parameter \(k\) will be called the \textit{level} of the corresponding symmetric functions.

**Theorem 6.1** (symmetry) \textit{The polynomials} \(\tilde{G}_\lambda^{(k)}, \tilde{H}_\mu^{(k)}\) \textit{and} \(H_\lambda^{(k)}\) \textit{are symmetric.}

This property follows from Corollary 6.3. Indeed, the commutation relation \([V_i, V_j] = 0\) proves that if \(\alpha\) is a rearrangement of a partition \(\mu\),

\[
V_{\alpha_1} \cdots V_{\alpha_r} |0\rangle = V_{\mu_r} \cdots V_{\mu_1} |0\rangle = \psi^k_q (h_\mu)
\]

which shows that for any partition \(\lambda\), the sets \(\text{Tab}_k(\lambda, \mu)\) and \(\text{Tab}_k(\lambda, \alpha)\) have the same spin polynomials.

**Remark 6.2** If one defines the linear operator \(\varphi^k_q\) as the adjoint of \(\psi^k_q\) for the standard scalar product, the \(H\)-functions can also be defined by the equation

\[
H_\lambda^{(k)}(X; q^{-2}) = \varphi^k_q (s_{k\lambda}).
\]  
(29)

There is strong experimental evidence for the following conjectures.

**Conjecture 6.3** (positivity) \textit{Their coefficients on the basis of Schur functions are polynomials with nonnegative integer coefficients.}

**Conjecture 6.4** (monotonicity) \(H_\mu^{(k+1)} - H_\mu^{(k)}\) is positive on the Schur basis.

**Conjecture 6.5** (plethysm) \textit{When} \(\mu = \nu^k\), \textit{for} \(\zeta\) \textit{a primitive} \(k\)-\textit{th root of unity,}

\[
H_\nu^{(k)}(\zeta) = (-1)^{(k-1)|\nu|} p_k \circ s_\nu
\]

and more generally, when \(d | k\) and \(\zeta\) is a primitive \(d\)-\textit{th root of unity,}

\[
H_\nu^{(k)}(\zeta) = (-1)^{(d-1)|\nu|/d} p_{k/d}^{k/d} \circ s_\nu.
\]

Equivalently,

\[
H_\nu^{(k)}(q) \mod 1 - q^k = \sum_{i=0}^{k-1} q^k \ell_k^{(i)} \circ s_\nu
\]

The following statements will be proved in the forthcoming sections.

**Theorem 6.6** \textit{For} \(k \geq \ell(\mu), H_\mu^{(k)}\) \textit{is equal to the Hall-Littlewood function} \(Q'_\mu\).
Theorem 6.7 The difference $Q'_\mu - H^{(2)}_\mu$ is nonnegative on the Schur basis.

Taking into account the results of [23, 26] and [2], this is sufficient to establish the conjectures for $k = 2$ and $k \geq \ell(\mu)$.

Example 6.8 (i) The 3-quotient of $\lambda = (3, 3, 3, 2, 1)$ is $((1), (1, 1), (1))$ and

$$G_{33321}(q) = m_{31} + (1 + q)m_{22} + (2 + 2q + q^2)m_{211} + (3 + 5q + 3q^2 + q^3)m_{1111} = s_{31} + qs_{22} + (q + q^2)s_{211} + q^3s_{1111}$$

is a $q$-analogue of the product

$$s_1s_1s_1 = s_{31} + s_{22} + 2s_{211} + s_{1111}.$$  

(ii) The $H$-functions associated to the partition $\lambda = (3, 2, 1, 1)$ are

$$H^{(2)}_{3211} = s_{3211} + q s_{322} + q s_{331} + q s_{4111} + (q + q^2) s_{421} + q^2 s_{43} + q^2 s_{511} + q^3 s_{52}$$

$$H^{(3)}_{3211} = s_{3211} + q s_{322} + (q + q^2) s_{331} + q s_{4111} + (q + 2q^2) s_{421} + (q^2 + q^3) s_{43} + (q^2 + q^3) s_{511} + 2q^3 s_{52} + q^4 s_{61}$$

$$H^{(4)}_{3211} = s_{3211} + q s_{322} + (q + q^2) s_{331} + q s_{4111} + (q + 2q^2 + q^3) s_{421} + (q^2 + q^3 + q^4) s_{43} + (q^2 + q^3 + q^4) s_{511} + (2q^3 + q^4 + q^5) s_{52} + (q^4 + q^5 + q^6) s_{61} + q^7 s_7$$

and we see that $s_{3211} < H^{(2)}_{3211} < H^{(3)}_{3211} < H^{(4)}_{3211} = Q'_{3211}$.

(iii) The plethysms of $s_2$ with the cyclic characters $\ell^{(i)}_3$ are given by the reduction modulo $1 - q^3$ of

$$H^{(3)}_{322111} = q^9 s_{63} + (q + 1)q^7 s_{621} + q^6 s_{6111} + (q + 1)q^7 s_{654} + (q^3 + 2q^2 + 2q + 1)q^5 s_{531} + (q^2 + 2q + 1)q^3 s_{522} + (q^3 + 2q^2 + 2q + 1)q^4 s_{51111} + (q + 1)q^4 s_{51111}$$

$$+ (q^2 + 2q + 1)q^5 s_{4411} + (q^3 + 2q^2 + 3q + 2)q^4 s_{432} + (2q^3 + 3q^2 + 3q + 1)q^3 s_{4311} + (q^3 + 3q^2 + 3q + 2)q^3 s_{4221} + (q^3 + 2q^2 + 2q + 1)q^2 s_{42111} + q^3 s_{411111} + (q + 1)q^3 s_{333} + (2q^3 + 3q^2 + 2q + 1)q^2 s_{3321} + (q^2 + 2q + 1)q^2 s_{33111} + (q^2 + 2q + 1)q^2 s_{3222}$$

$$+ (q^3 + 2q^2 + 2q + 1)q s_{32211} + (q + 1)q s_{321111} + (q + 1)q s_{22221} + s_{222111}$$
Indeed,

\[ H^{(3)}_{221111} \mod 1 - q^3 = (2s_{5211} + s_{22221} + s_{321111} + 3s_{4311} + 2s_{32211} + 3s_{321111} + 3s_{231111} + s_{2321} + 3s_{33211} + 3s_{32111} + s_{2322} + s_{51111} + s_{522} + 3s_{432} + 3s_{42111} + s_{54} + s_{621} + s_{441})q^2 \\
+ (2s_{5211} + s_{22221} + s_{321111} + 3s_{4311} + 2s_{32211} + s_{522} + 3s_{432} + 3s_{33211} + s_{33111} + s_{3222} + s_{51111} + s_{522} + 3s_{432} + 3s_{42111} + s_{54} + s_{621} + s_{441})q \\
+ 2s_{33111} + s_{63} + s_{6111} + 2s_{3311} + 2s_{522} + 2s_{5211} + 2s_{441} + 2s_{432} + 3s_{4311} + 3s_{4221} + 2s_{42111} + s_{411111} + 2s_{333} + 2s_{3321} + 2s_{3222} + s_{222111} + 2s_{32211} \\
= q^2 \ell^{(2)}_3 \circ s_{21} + q\ell^{(1)}_3 \circ s_{21} + \ell^{(0)}_3 \circ s_{21} .
\]

7 The case of dominoes

For \( k = 2 \), the conjectures can be established by means of the combinatorial constructions of \([2]\) and \([19]\). In this case, conjectures 6.1, 6.3 and 6.5 follow directly from the results of \([2]\), and the only point remaining to be proved is Theorem 6.7.

The important special feature of domino tableaux is that there exists a natural notion of Yamanouchi domino tableau. These tableaux correspond to highest weight vectors in tensor products of two irreducible \( GL_n \)-modules, in the same way as ordinary Yamanouchi tableaux are the natural labels for highest weight vectors of irreducible representations.

The column reading of a domino tableau \( T \) is the word obtained by reading the successive columns of \( T \) from top to bottom and left to right. Horizontal dominoes, which belong to two successive columns \( i \) and \( i + 1 \) are read only once, when reading column \( i \). For example, the column reading of the domino tableau

\[
\begin{array}{c}
4 \\
3 \\
2 & 2 \\
1 & 1
\end{array}
\]

is \( \text{col} (T) = 431212 \).

A Yamanouchi word is a word \( w = x_1x_2 \cdots x_n \) such that each right factor \( v = x_i \cdots x_n \) of \( w \) satisfies \( |v|_j \geq |v|_{j+1} \) for each \( j \), where \( |v|_j \) denotes the number of occurrences of the letter \( j \) in \( v \).

A Yamanouchi domino tableau is a domino tableau whose column reading is a Yamanouchi word. We denote by \( \text{Yam}_2(\lambda, \mu) \) the set of Yamanouchi domino tableaux of shape \( \lambda \) and weight \( \mu \).
It follows from the results of [2], Section 7, that the Schur expansions of the $H$-functions of level 2 are given by

$$H^{(2)}_{\lambda} = \sum_{\mu} \sum_{T \in \text{Yam}_2(2\lambda, \mu)} q^{s(T)} s_\mu .$$

(30)

On the other hand,

$$Q'_{\lambda} = \sum_{\mu} \sum_{t \in \text{Tab} (\mu, \lambda)} q^{c(t)} s_{\mu} .$$

(31)

To prove Theorem 6.7, it is thus sufficient to exhibit an injection

$$\eta : \text{Yam}_2(2\lambda, \mu) \longrightarrow \text{Tab} (\mu, \lambda)$$

satisfying

$$c(\eta(T)) = s(T) .$$

To achieve this, we shall make use of a bijection described in [1], and extended in [19], which sends a domino tableau $T \in \text{Tab}_2(\alpha, \mu)$ over the alphabet $X = \{1, \ldots, n\}$, to an ordinary tableau $t = \phi(T) \in \text{Tab}(\alpha, \bar{\mu})$ over the alphabet $\bar{X} = \{\bar{n} < \ldots < \bar{1} < \ldots < n\}$. The weight $\bar{\mu}$ means that $t$ contains $\mu_i$ occurrences of $i$ and of $\bar{i}$. The tableau $\phi(T)$ is invariant under Schützenberger’s involution $\Omega$, and the spin of $T$ can be recovered from $t$ by the following procedure [20].

Let $\alpha = 2\lambda$, $\beta = \alpha'$, $\beta_{\text{odd}} = (\beta_1, \beta_3, \ldots)$ and $\beta_{\text{even}} = (\beta_2, \beta_4, \ldots)$. Then, there exists a unique factorisation $t = \tau_1 \tau_2$ in the plactic monoid $\text{Pl}(X \cup \bar{X})$, such that $\tau_1$ is a contetableau of shape $\alpha^1 = (\bar{\beta}_{\text{even}})'$ and $\tau_2$ is a tableau of shape $\alpha^2 = (\beta_{\text{odd}})'$. The spin of $T = \phi^{-1}(t)$ is then equal to the number $|\tau_1|_+$ of positive letters in $\tau_1$, which is also equal to the number $|\tau_2|_-$ of negative letters in $\tau_2$. Moreover, $\tau_2 = \Omega(\tau_1)$.

**Example 7.1** With the following tableau $T$ of shape $(4, 4, 2, 2)$, one finds

$$T = \begin{array}{cccc}
3 \\
2 \\
1 & 2 \\
1 & 1 \\
\end{array} \quad \begin{array}{cccc}
1 & 3 \\
1 & 2 \\
2 & 1 & 1 & 2 \\
3 & 2 & 1 & 1 \\
\end{array}$$

By *jeu de taquin*, we find that in the plactic monoid

$$t = \begin{array}{cccc}
1 & 1 & 3 \\
2 & 1 & 2 \\
2 & 1 & 2 \\
3 & 1 & 1 \\
\end{array} = \tau_1 \tau_2 .$$

The number of positive letters of $\tau_1$ and the number of negative letters of $\tau_2$ are both equal to 1, which is the spin of $T$. 

24
This correspondence still works in the general case ($\alpha$ need not be of the form $2\lambda$) and the invariant tableau associated to a domino tableau $T$ admits a similar factorisation $t = \tau_1 \tau_2$, but in general $\tau_2 \neq \Omega(\tau_1)$ and the formula for the spin is $s(T) = \frac{1}{2}(|\tau_1|_+ + |\tau_2|_-)$.

The map $\eta : \text{Yam}_2(2\lambda, \mu) \rightarrow \text{Tab} (\mu, \lambda)$ is given by the following algorithm: to compute $\eta(T)$,

1. construct the invariant tableau $t = \phi(T)$

2. apply the jeu de taquin algorithm to $t$ to obtain the plactic factorization $t = \tau_1 \tau_2$, and keep only $\tau_2$.

3. Apply the evacuation algorithm to the negative letters of $\tau_2$, keeping track of the successive stages. After all the negative letters have been evacuated, one is left with a Yamanouchi tableau $\tau$ in positive letters.

4. Complete the tableau $\tau$ to obtain the tableau $t' = \eta(T)$ using the following rule: suppose that at some stage of the evacuation, the box of $\tau_2$ which disappeared after the elimination of $\bar{i}$ was in row $j$ of $\tau_2$. Then add a box numbered $j$ to row $i$ of $\tau$.

**Theorem 7.2** The above algorithm defines an injection

$$\eta : \text{Yam}_2(2\lambda, \mu) \rightarrow \text{Tab} (\mu, \lambda)$$

satisfying $c \circ \eta = s$.

**Corollary 7.3** $H^{(2)}_\lambda \leq Q'_\lambda$

**Example 7.4** Let $T$ be the following Yamanouchi domino tableau, which is of shape $2\lambda = (6, 4, 4, 2, 2)$, of weight $\mu = (4, 3, 2)$ and has spin $s(T) = 3$

$$T = \begin{array}{|c|c|}
\hline
3 & 3 \\
\hline
2 & 2 \\
\hline
1 & 1 & 2 & 1 & 1 \\
\hline
\end{array}$$

Then,

$$\phi(T) = \begin{array}{|c|c|}
\hline
3 & 3 \\
\hline
1 & 2 \\
\hline
1 & 1 & 2 & 2 \\
\hline
2 & 2 & 1 & 1 \\
\hline
3 & 3 & 2 & 1 & 1 \\
\hline
\end{array} \equiv \begin{array}{|c|c|}
\hline
1 & 1 & 3 & 3 \\
\hline
1 & 2 & 2 \\
\hline
2 & 1 & 1 & 2 \\
\hline
2 & 2 & 1 \\
\hline
3 & 3 & 1 & 1 \\
\hline
\end{array}$$
and the successive stages of the evacuation process are

\[
\begin{array}{ccc}
3 & \times & 3 \\
2 & \times & 2 \\
1 & \times & 1 \\
\hline
3 & 3 & 2 \\
2 & 2 & 1 \\
1 & 1 & 1 \\
\end{array}
\quad \rightarrow \quad
\begin{array}{ccc}
3 & \times & 3 \\
2 & \times & 2 \\
1 & \times & 1 \\
\hline
3 & 2 & 2 \\
2 & 1 & 1 \\
1 & 1 & 1 \\
\end{array}
\quad \rightarrow \quad
\begin{array}{ccc}
3 & \times & 3 \\
2 & \times & 2 \\
1 & \times & 1 \\
\hline
3 & 1 & 1 \\
2 & 1 & 1 \\
1 & 1 & 1 \\
\end{array}
\]

so that we find

\[
\eta(T) = \begin{array}{ccc}
3 & 5 & 2 \\
1 & 1 & 1 \\
\end{array}
\]

a tableau of shape \( \mu = (4, 3, 2) \), weight \( \lambda = (3, 2, 2, 1, 1) \) and charge \( c(t') = 3 \).

8 The stable case

As the \( Q' \)-functions are known to verify all the conjectured properties of \( H \)-functions, the stable case of the conjectures will be a consequence of theorem 6.6. This result will be proved by means of Shimomura’s cell decompositions of unipotent varieties.

8.1 Unipotent varieties

Let \( u \in GL(n, \mathbb{C}) \) be a unipotent element, and let \( F^u_\nu[\mathbb{C}] \) be the variety of \( \nu \)-flags of \( \mathbb{C}^n \) which are fixed by \( u \).

It has been shown by N. Shimomura (145, see also [12]) that the variety \( F^u_\nu[\mathbb{C}] \) admits a cell decomposition, involving only cells of even real dimensions. More precisely, this cell decomposition is a partition in locally closed subvarieties, each being algebraically isomorphic to an affine space. Thus, the odd-dimensional homology groups are zero, and if

\[
\Pi_{\nu \mu}(t^2) = \sum_i t^{2i} \dim H_{2i}(F^u_\nu, \mathbb{Z})
\]

is the Poincaré polynomial of \( F^u_\nu[\mathbb{C}] \), one has \( |F^u_\nu[F_q]| = \Pi_{\nu \mu}(q) \). But this is also equal to \( \tilde{G}_{\nu \mu}(q) \), and as this is true for an infinite set of values of \( q \), one has \( \Pi_{\nu \mu}(z) = \tilde{G}_{\nu \mu}(z) \) as polynomials. That is, the coefficient of \( \tilde{Q}'_\mu \) on the monomial function \( m_\nu \) is the Poincaré polynomial of \( F^u_\nu \), for a unipotent \( u \) of type \( \mu \).

Writing

\[
\tilde{Q}'_\mu = \sum_{\lambda, \nu} \tilde{K}_{\lambda \mu(q)} K_{\lambda \nu} m_\nu ,
\]

one sees that

\[
\tilde{G}_{\nu \mu}(q) = \sum_{(t_1, t_2) \in \text{Tab}(\lambda, \mu) \times \text{Tab}(\nu, \mu)} q^{\tilde{c}(t)} .
\]
Knuth’s extension of the Robinson-Schensted correspondence \cite{22} is a bijection between the set
\[ \prod_{\lambda} \text{Tab} (\lambda, \mu) \times \text{Tab} (\lambda, \nu) \]
of pairs of tableaux with the same shape, and the double coset space \( S_\mu \backslash S_n / S_\nu \) of the symmetric group \( S_n \) modulo two parabolic subgroups. Double cosets can be encoded by two-line arrays, integer matrices with prescribed row and column sums, or by tabloids.

Let \( \nu \) and \( \mu \) be arbitrary compositions of the same integer \( n \). A \( \mu \)-tabloid of shape \( \nu \) is a filling of the diagram of boxes with row lengths \( \nu_1, \nu_2, \ldots, \nu_r \), the lowest row being numbered 1 (French convention for tableaux), such that the number \( i \) occurs \( \mu_i \) times, and such that each row is nondecreasing. For example,
\[
\begin{array}{ccc}
3 & & \\
1 & 1 & 1 \\
1 & 1 & 3 \\
2 & 3 & \\
\end{array}
\]
is a \((5, 1, 3)\)-tabloid of shape \((2, 3, 3, 1)\).

We denote by \( L(\nu, \mu) \) the set of tabloids of shape \( \nu \) and weight \( \mu \). A tabloid will be identified with the word obtained by reading it from left to right and top to bottom. Then,
\[
\tilde{G}_{\nu\mu}(q) = \sum_{T \in L(\nu, \mu)} q^{\tilde{c}(T)}.
\]

**Example 8.1** To compute \( \tilde{G}_{42,321}(q) \) one lists the elements of \( L((4, 2), (3, 2, 1)) \), which are
\[
\begin{array}{cccc}
2 & 3 & & \\
1 & 1 & 1 & 2 \\
1 & 1 & 1 & 3 \\
1 & 1 & 2 & 2 \\
1 & 1 & 2 & 3 \\
1 & 1 & 2 & 2 & 3 \\
\end{array}
\]
Reading them as prescribed, we obtain the words
\[
231112 \quad 221113 \quad 131122 \quad 121123 \quad 111223
\]
whose respective charges are 2, 1, 3, 2, 4. The cocharge polynomial is thus \( \tilde{G}_{42,321}(q) = 1 + q + 2q^2 + q^3 \).

In Shimomura’s decomposition of the fixed point variety \( F_\mu^\nu \) of a unipotent of type \( \nu \), the cells are indexed by tabloids of shape \( \nu \) and weight \( \mu \). The dimension \( d(T) \) of the cell \( c_T \) indexed by \( T \in L(\nu, \mu) \) is computed by an algorithm described below, and gives another combinatorial interpretation of the polynomial \( \tilde{G}_{\nu\mu}(q) \), exchanging the roles of shape and weight:
\[
\tilde{G}_{\mu\nu} = \sum_{T \in L(\mu, \nu)} q^{\tilde{c}(T)} = \sum_{T \in L(\nu, \mu)} q^{d(T)}.
\]
The dimensions \( d(T) \) are given by the following algorithm.
1. If $T \in L(\nu, (n))$ then $d(T) = 0$;

2. If $\mu = (\mu_1, \mu_2)$ has exactly two parts, and $T \in L(\nu, \mu)$, then $d(T)$ is computed as follows. A box $\alpha$ of $T$ is said to be special if it contains the rightmost 1 of its row. For a box $\beta$ of $T$, put $d(\beta) = 0$ if $\beta$ does not contain a 2, and if $\beta$ contains a 2, set $d(\beta)$ equal to the number of nonspecial 1’s lying in the column of $\beta$, plus the number of special 1’s lying in the same column, but in a lower position. Then

$$d(T) = \sum_\beta d(\beta) .$$

3. Let $\mu = (\mu_1, \ldots, \mu_k)$ and $\mu^* = (\mu_1, \ldots, \mu_{k-1})$. For $T \in L(\nu, \mu)$, let $T_1$ be the tabloid obtained by changing the entries $k$ into 2 and all the other ones into 1. Let $T_2$ be the tabloid obtained by erasing all the entries $k$, and rearranging the rows in the appropriate order. Then,

$$d(T) = d(T_1) + d(T_2) .$$

Example 8.2 With $T = \begin{array}{c c c}
1 & 1 & 1 \\
4 & 2 & 3 \\
1 & 1 & 2
\end{array} \in L(332, 4211)$, one has

$T_1 := \begin{array}{c c c}
1 & 2 \\
1 & 1 & 1 \\
1 & 1 & 1
\end{array}$

$T_2 = \begin{array}{c c c}
1 & 2 \\
1 & 1 & 2 \\
1 & 1 & 1
\end{array}$

$T_{21} = \begin{array}{c c c}
1 & 2 \\
1 & 1 & 1 \\
1 & 1 & 1
\end{array}$

$T_{22} = \begin{array}{c c c}
1 & 2 \\
1 & 1 & 1
\end{array}$

where the special entries are printed in boldtype. Thus, $d(T) = t(T_1) + d(T_2) = 2 + d(T_{21}) + d(T_{22}) = 4$.

We shall need a variant of this construction, in which the shape $\nu$ is allowed to be an arbitrary composition, and where in step 3, the rearranging of the rows is suppressed. Such a variant has already been used by Terada [48] in the case of complete flags.

That is, we associate to a tabloid $T \in L(\nu, \mu)$ an integer $e(T)$, defined by

1. For $T \in L(\nu, (n))$, $e(T) = d(T) = 0$;
2. For $T \in L(\nu, (\mu_1, \mu_2))$, $e(T) = d(T)$;
3. Otherwise $e(T) = e(T_1) + e(T_2)$ where $T_1$ is defined as above, but this time $T_2$ is obtained from $T$ by erasing the entries $k$, without reordering.

Lemma 8.3 Let $\lambda = (\lambda_1, \ldots, \lambda_r)$ be a partition, and let $\nu = \lambda \cdot \sigma = (\lambda_{\sigma(1)}, \ldots, \lambda_{\sigma(r)})$, $\sigma \in S_r$. Then, the distribution of $e$ on $L(\nu, \mu)$ is the same as the distribution of $d$ on $L(\lambda, \mu)$. That is,

$$D_{\lambda\mu}(q) = \sum_{T \in L(\lambda, \mu)} q^{d(T)} = E_{\nu\mu}(q) = \sum_{T \in L(\nu, \mu)} q^{e(T)} .$$

In particular, $D_{\lambda\mu}(q) = E_{\lambda\mu}(q)$.
Proof — This could be proved by repeating word for word the geometric argument of [13]. We give here a short combinatorial argument. As the two statistics coincide on tabloids whose shape is a partition and whose weight has at most two parts, the only thing to prove, thanks to the recurrence formula, is that $e$ has the same distribution on $L(\beta, (\mu_1, \mu_2))$ as on $L(\alpha, (\mu_1, \mu_2))$ when $\beta$ is a permutation of $\alpha$. The symmetric group being generated by the elementary transpositions $\sigma_i = (i, i+1)$, one may assume that $\beta = \alpha \sigma_i$. We define the image $T\sigma_i$ of a tabloid $T \in L(\alpha, (\mu_1, \mu_2))$ by distinguishing among the following configurations for rows $i$ and $i+1$:

1. $x_1 \ldots x_k 2 2^r \sigma_i x_1 \ldots x_k 2 2^s$
   $1 \ldots 1 1 2^s \quad \longrightarrow \quad 1 \ldots 1 1 2^r$

2. $x_1 \ldots x_k 2 2^s \sigma_i 1 \ldots 1 1 2^r$
   $1 \ldots 1 1 2^r \quad \longrightarrow \quad x_1 \ldots x_k 2 2^s$

3. In all other cases, the two rows are exchanged:
   $x_1 \ldots x_r \sigma_i y_1 \ldots y_s$
   $y_1 \ldots y_s \quad \longrightarrow \quad x_1 \ldots x_r$

From this definition, it is clear that $e(T\sigma_i) = e(T)$. Moreover, it is not difficult to check that this defines an $e$-preserving action of the symmetric group $S_m$ on the set of $\mu$-tabloids with $m$ rows, such that $L(\alpha, \mu)\sigma = L(\alpha \sigma, \mu)$ (the only point needing a verification is the braid relation $\sigma_i \sigma_{i+1} \sigma_i = \sigma_{i+1} \sigma_i \sigma_{i+1}$).

Thus, for a partition $\lambda$ and a two-part weight $\mu = (\mu_1, \mu_2)$, $d$ and $e$ coincide on $L(\lambda, \mu)$, and for $\sigma \in S_m$, $E_{\lambda, \mu, \sigma}(q) = D_{\lambda, \mu}(q)$. Now, by induction, for $\mu = (\mu_1, \ldots, \mu_k)$,

$$D_{\lambda, \mu}(q) = \sum_{T \in L(\lambda, \mu)} q^{d(T_1)} q^{d(T_2)}$$

$$= \sum_{\lambda=\text{shape}(T_1)} q^{d(T_1)} D_{\lambda, \mu^*}(q) = \sum_{\lambda=\text{shape}(T_1)} e^{e(T_1)} E_{\lambda, \mu^*}(q) = E_{\lambda, \mu}(q).$$

Example 8.4 Take $\lambda = (3, 2, 1)$, $\mu = (4, 2)$ and $\nu = \lambda \sigma_1 \sigma_2 = (3, 1, 2)$. The $\mu$-tabloids of shape $\lambda$ are

$$T \quad d(T)$$

|   |   |   |   |   |   |
|---|---|---|---|---|---|
| 2 | 1 | 2 | 1 | 1 | 1 |
| 1 | 1 | 1 | 1 | 2 | 1 |
| 2 | 2 | 1 | 1 | 1 | 1 |
| 1 | 1 | 1 | 1 | 1 | 2 |

The $\nu$-tabloids of shape $\lambda$ are

$$T \quad e(T)$$

|   |   |   |   |   |   |
|---|---|---|---|---|---|
| 2 | 2 | 1 | 1 | 1 | 1 |
| 1 | 1 | 1 | 1 | 1 | 1 |
| 1 | 1 | 1 | 1 | 1 | 1 |
| 2 | 1 | 1 | 1 | 1 | 1 |
| 2 | 2 | 1 | 1 | 1 | 1 |
| 1 | 1 | 2 | 1 | 1 | 1 |

29
Thus, $D_{\lambda\mu}(q) = E_{\nu\mu}(q) = 1 + q + 2q^2 + q^3 = \tilde{G}_{\mu \lambda}(q)$. The tabloids contributing a term $q^2$ are apparied in the following way:

Remark 8.5 The only property that we shall need in the sequel is the equality $D_{\lambda\mu}(q) = E_{\lambda\mu}(q)$. However, it is possible to be more explicit by constructing a bijection exchanging $d$ and $e$. The above action of $S_m$ can be extended to tabloids with arbitrary weight, still preserving $e$. Suppose for example that we want to apply $\sigma_i$ to a tabloid $T$ whose restriction to rows $i, i+1$ is

One first determines the positions of the greatest entries, which are the 9's, in $T\sigma_i$. Starting with an empty diagram of the permuted shape (10, 7), one constructs $T_1$ as above by converting all the entries 9 of $T$ into 2 and the remaining ones into 1. Then we apply $\sigma_i$ to $T_1$, and the positions of the 2 in $T_1\sigma_i$ give the positions of the 9 in $T\sigma_i$. Then, the entries 9 are removed from $T$ ad the procedure is iterated until one reaches a tabloid whose rows $i$ and $i+1$ are of equal lengths. This tabloid is then copied (without permutation) in the remaining part of the result. On the example, this gives
8.2 Labelling of cells by ribbon tableaux

A tabloid $t$ of shape $\nu = (\nu_1, \ldots, \nu_k)$ can be identified with a $k$-tuple $(w_1, \ldots, w_k)$ of words, $w_i$ being a row tableau of length $\nu_i$. The Stanton-White correspondence $\psi$ associates to such a $k$-tuple of tableaux a $k$-ribbon tableau $T = \psi(t)$. Thus, the cells of a unipotent variety $F^u_\mu$ (where $u$ is of type $\nu$) are labelled by $k$-ribbon tableaux of a special kind. The following theorem, which implies the stable case of the conjectures, shows that this labelling is natural from a geometrical point of view.

**Theorem 8.6** The Stanton-White correspondence $\psi$ sends a tabloid $t \in L(\nu, \mu)$ onto a ribbon tableau $T = \psi(t)$ whose cospin is equal to the dimension of the cell $c_t$ of $F^u_\mu$ labelled by $t$, when one uses the modified indexation for which the dimension of $c_t$ is $e(t)$ (see Section 3). That is,

$$\tilde{s}(\psi(t)) = e(t).$$

The proof, which is just a direct verification, will not be given here.

At this point, it is useful to observe, following [18], that the $e$-statistic can be given a nonrecursive definition, as a kind of inversion number. Let $t = (w_1, \ldots, w_k)$ be a tabloid, identified with a $k$-tuple of row tableaux. Let $y$ be the $r$-th letter of $w_i$ and $x$ be the $r$-th letter of $w_j$, and suppose that $x < y$. Then, the pair $(y, x)$ is said to be an $e$-inversion if either

(a) $i < j$

or

(b) $i > j$ and there is on the right of $x$ in $w_j$ a letter $u < y$

Then $e(t)$ is equal to the number of inversions $(y, x)$ in $t$.

**Example 8.7** Let $t \in L((2, 3, 2, 1), (2, 3, 1, 1, 1))$ be the following tabloid (the number under a letter $y$ is the number of $e$-inversions of the form $(y, x)$):

$$t = \left(\begin{array}{c|ccc} 2 & 3 & \hline 1 & 1 & 2 \end{array}, \begin{array}{c|ccc} 4 & 5 \hline 3 & 1 \end{array}, \begin{array}{c} 2 \end{array}\right)$$

so that $e(t) = 7$. Its image under the SW-correspondence is the 4-ribbon tableau

$$\begin{array}{c|c|c|c} & & & \\
\hline 4 & 5 & \hline 2 & 3 & 5 & \hline 1 & 2 \end{array}$$

whose cospin is equal to 7.
8.3 Atoms

The $H$-functions indexed by columns can also be completely described in terms of Hall-Littlewood functions.

**Proposition 8.8** Let $n = sk + r$ with $0 \leq r < k$, and set $\lambda = ((s+1)^r, s^{k-r})$. Then,

$$H_{(1^n)}^{(k)} = \omega \left( \tilde{Q}_\lambda \right)$$

where $\omega$ is the involution $s_\lambda \mapsto s_{\lambda'}$.

The $k$-quotient of $(k^n)$ is $(1^s, \ldots, 1^s, 1^{s+1}, \ldots, 1^{s+1})$, where the partition $(1^s)$ is repeated $k - r$ times. Thus, a $k$-ribbon tableau is mapped by the Stanton-White correspondence to a $k$-tuple of columns, which can be interpreted as a tabloid, and the result follows again from Shimomura’s decomposition.

The partitions arising in Proposition 8.8 have the property that, if $\leq$ denotes the natural order on partitions,

$$\alpha \leq \lambda \iff \ell(\alpha) \leq \ell(\mu).$$

There are canonical injections

$$\iota_{\alpha\beta} : \text{Tab}(\cdot, \alpha) \rightarrow \text{Tab}(\cdot, \beta)$$

when $\alpha \leq \beta$ (cf. [31, 24]). The atom $A(\mu)$ is defined as the set of tableaux in $\text{Tab}(\cdot, \mu)$ which are not in the image of any $\iota_{\alpha\mu}$. Define the symmetric functions (cocharge atoms)

$$\tilde{A}_\mu(X; q) = \sum_\lambda \left( \sum_{t \in A(\mu) \cap \text{Tab}(\lambda, \mu)} q^{\tilde{c}(t)} \right) s_\lambda(X). \quad (37)$$

Proposition 8.8 can then be rephrased as

$$H_{(1^n)}^{(k)} = \omega \left( \sum_{\ell(\mu) \leq k} \tilde{A}_\mu \right). \quad (38)$$

It seems that the difference between the stable $H$-functions and the immediately lower level can also be described in terms of atoms. For $\ell(\lambda) = r$, set

$$\tilde{D}_\lambda(q) = \tilde{H}_\lambda^{(r)} - \tilde{H}_\lambda^{(r-1)}.$$

These functions seem to be sums of cocharge atoms over certain intervals in the lattice of partitions.

**Conjecture 8.9** For any partition $\lambda$, there exists a partition $f(\lambda)$ such that

$$\tilde{D}_\lambda = \sum_{\mu \leq f(\lambda)} \tilde{A}_\mu.$$

**Example 8.10** In weight 6, the partition $f(\lambda)$ is given by the following table:

| $\lambda$  | (51) | (42) | (411) | (33) | (321) | (3111) | (222) | (2211) | (21111) | (111111) |
|-------------|------|------|-------|------|-------|--------|-------|-------|--------|----------|
| $f(\lambda)$ | (6)  | (51) | (51)  | (42) | (42)  | (411)  | (321) | (321) | (3111) | (21111)  |
