Filling boundaries of coarse manifolds in semisimple and solvable arithmetic groups

Received June 20, 2011 and in revised form March 3, 2012

Abstract. We provide partial results towards a conjectural generalization of a theorem of Lubotzky–Mozes–Raghunathan for arithmetic groups (over number fields or function fields) that implies, in low dimensions, both polynomial isoperimetric inequalities and finiteness properties.

As a tool in our proof, we establish polynomial isoperimetric inequalities and finiteness properties for certain solvable groups that appear as subgroups of parabolic groups in semisimple groups, thus generalizing a theorem of Bux.

We also develop a precise version of reduction theory for arithmetic groups whose proof is, for the most part, independent of whether the underlying global field is a number field or a function field.

Our main result is Theorem 4 below. Before stating it, we provide some background.

0.1. Arithmetic groups

Let $K$ be a global field (number field or function field), and let $S$ be a nonempty set of finitely many inequivalent valuations of $K$ including one from each class of archimedean valuations. The ring $\mathcal{O}_S \subseteq K$ will denote the corresponding ring of $S$-integers.

For any $v \in S$, we let $K_v$ be the completion of $K$ with respect to $v$ so that $K_v$ is a locally compact field.

Let $\mathbf{G}$ be a noncommutative, absolutely almost simple, $K$-isotropic $K$-group. Let $G$ be the semisimple Lie group

$$G = \prod_{v \in S} \mathbf{G}(K_v)$$

endowed with a left-invariant metric. Notice that $|S|$ is the number of simple factors of $G$.

Under the diagonal embedding, the arithmetic group $\mathbf{G}(\mathcal{O}_S)$ is a lattice in $G$. The lattice being noncocompact is equivalent to the assumption that $\mathbf{G}$ is $K$-isotropic. The metric on $G$ restricts to a metric on $\mathbf{G}(\mathcal{O}_S)$.

Denote the Euclidean, or geometric, rank of $G$ by $k(\mathbf{G}, S)$, so that

$$k(\mathbf{G}, S) = \sum_{v \in S} \text{rank}_{K_v} \mathbf{G}.$$
0.2. Word metric for higher rank arithmetic groups

If $k(G, S) \geq 2$, then $G(\mathcal{O}_S)$ is well-known to be finitely generated. Thus, $G(\mathcal{O}_S)$ can be endowed with a proper left-invariant word metric. Lubotzky–Mozes–Raghunathan [13] showed that the word metric is determined by $G$ by proving

**Theorem 1.** The diagonal embedding $G(\mathcal{O}_S) \hookrightarrow G$ is a quasi-isometric embedding when $k(G, S) \geq 2$.

Bux–Wortman conjectured a natural generalization to the above theorem in [7]. We introduce a slight reformulation of that conjecture as Conjecture 2 below. The reformulated version better illustrates the lack of dependence on whether the local fields $K_v$ are archimedean.

Before stating the conjecture, we must introduce the notion of a coarse manifold.

0.3. Coarse manifolds

A coarse manifold $\Sigma$ in a metric space $X$ is a function from the vertices of a triangulated manifold $M$ into $X$. In a slight abuse of language, we refer to the image of a coarse manifold as a coarse manifold, thus a coarse manifold in $X$ will be regarded as a subset of $X$.

Given a coarse manifold $\Sigma$, we define $\partial \Sigma$ as the restriction of the function defining $\Sigma$ to $\partial M$.

We say $\Sigma$ has scale $r > 0$ if every pair of adjacent vertices in $M$ map to within distance $r$ of each other in $X$. We define the volume of $\Sigma$ to be the number of vertices in $M$.

If $M$ is an $n$-manifold, we call $\Sigma$ a coarse $n$-manifold. If $\Sigma'$ is a coarse manifold as well whose domain is the triangulated manifold $M'$, then we say that $\Sigma$ and $\Sigma'$ have the same topological type if $M$ and $M'$ are homeomorphic.

0.4. Expanding on Lubotzky–Mozes–Raghunathan

Having introduced the proper terminology, we state

**Conjecture 2.** Given $G(\mathcal{O}_S)$ as above and a scale factor $r_1$, there exists a linear polynomial $f$ and a scale factor $r_2$ such that if $\Sigma \subseteq G$ is a coarse $n$-manifold of scale $r_1$, with $\partial \Sigma \subseteq G(\mathcal{O}_S)$, and $n < k(G, S)$, then there is a coarse $n$-manifold $\Sigma' \subseteq G(\mathcal{O}_S)$ of scale $r_2$, with the same topological type as $\Sigma$, and such that $\partial \Sigma' = \partial \Sigma$ and $\text{vol}(\Sigma') \leq f(\text{vol}(\Sigma))$.

The bound of $n < k(G, S)$ is known to be sharp in many cases. Indeed, Bux–Wortman showed the bound is sharp when $K$ is a function field [7], Taback showed it is sharp when $G(\mathcal{O}_S) = \text{SL}_2(\mathbb{Z}[1/p])$ [18], and Wortman showed it was sharp if every place in $S$ is archimedean and the $K$-type of $G$ is $A_n$, $B_n$, $C_n$, $D_n$, $E_6$ or $E_7$ [19]. The bound was conjectured to be sharp in general in [7].
Notice that Lubotzky–Mozes–Raghunathan (Theorem 1) would quickly follow from Conjecture 2. Indeed, let \( \gamma_1, \gamma_2 \in G(O_S) \). Because \( G \) is quasi-isometric to a product of symmetric spaces and Euclidean buildings, there exist \( r_1 > 0, L \geq 1, \) and \( C \geq 0 \) (that depend only on \( G \)) and a coarse path \( \Sigma \subseteq G \) of scale \( r_1 \) such that \( \partial \Sigma = \{ \gamma_1, \gamma_2 \} \) and the volume of \( \Sigma \) is bounded above by \( Ld(\gamma_1, \gamma_2) + C \). We let \( r_2 \) and \( f \) be as in Conjecture 2, so there is a coarse path \( \Sigma \subseteq G(O_S) \) of scale \( r_2 > 0 \) and volume bounded above by \( f(Ld(\gamma_1, \gamma_2) + C) \). We may assume the finite generating set of \( G(O_S) \) contains all elements of \( G(O_S) \) whose distance from 1 is less than \( r_2 \), so the theorem follows.

0.5. Isoperimetric inequalities

Recall that a group \( \Gamma \) is of type \( F_n \) if there is a \( K(\Gamma, 1) \) with finite \( n \)-skeleton.

If a group \( \Gamma \) is of type \( F_n \), then we let \( X \) be an \( (n - 1) \)-connected CW-complex that \( \Gamma \) acts on cellularly, properly, and cocompactly. Suppose \( 1 \leq m \leq n - 1 \). If there are constants \( L, t \geq 1 \) and \( C \geq 0 \) such that for any cellular \( m \)-sphere \( \Sigma \subseteq X \) there is a cellular \( (m + 1) \)-disk \( D \subseteq X \) such that \( \partial D = \Sigma \) and \( \text{vol}(D) \leq L \text{vol}(\Sigma) + C \), then we say that \( \Gamma \) satisfies a polynomial \( m \)-dimensional isoperimetric inequality. (Here the volume of \( \Sigma \) and \( D \) are the numbers of cells they contain.)

If in the above \( t \) can be taken to be \( (m + 1)/m \), then we say that \( \Gamma \) satisfies a Euclidean \( m \)-dimensional isoperimetric inequality.

Satisfying a polynomial or Euclidean \( m \)-dimensional isoperimetric inequality is well-known to be a quasi-isometry invariant, so it is independent of the choice of the space \( X \).

Using a similar argument to that given in the proof above that Conjecture 2 implies Theorem 1, we can take any coarse sphere \( \Sigma \subseteq G(O_S) \) of dimension \( m \leq k(G, S) - 2 \), find a coarse \( (m + 1) \)-disk in \( G \) whose boundary is \( \Sigma \) and whose volume is Euclidean with respect to \( \Sigma \) (\( G \) is quasi-isometric to a product of symmetric spaces and Euclidean buildings so this is always possible), and then use Conjecture 2 to find a corresponding coarse \( (m + 1) \)-disk in \( G(O_S) \) whose boundary is \( \Sigma \) and whose volume is Euclidean with respect to \( \Sigma \). This brief sketch of a proof will be made precise in Section 7, and it proves that Conjecture 2 would imply

**Conjecture 3.** \( G(O_S) \) satisfies a Euclidean \( m \)-dimensional isoperimetric inequality if \( m \leq k(G, S) - 2 \). In particular, the Dehn function for \( G(O_S) \) is quadratic if \( k(G, S) \geq 3 \).

Thurston’s conjecture that \( \text{SL}_3(\mathbb{Z}) \) has a quadratic Dehn function is a special case of Conjecture 3 since \( \text{rank}_R \text{SL}_3 = 3 \).

As evidence for Conjecture 3, Drutu [8] proved that \( G(O_S) \) has a Dehn function that is bounded above by the function \( x \mapsto x^{2+R} \) for any \( 0 < R < 0 \) if \( S \) contains only archimedean valuations, the \( K \)-rank of \( G \) equals 1, and \( k(G, S) \geq 3 \).

Young [21] proved that if \( G(O_S) = \text{SL}_n(\mathbb{Z}) \), then \( G(O_S) \) has a quadratic Dehn function if \( n \geq 5 \). The condition \( n \geq 5 \) implies \( k(G, S) \geq 4 \).

The work of Drutu and Young contains the only results in the literature that establish polynomial \( m \)-dimensional isoperimetric inequalities for noncocompact arithmetic groups when \( m \leq k(G, S) - 2 \).
0.6. Main result

The main result proved in this paper is partial progress in proving Conjecture 2. Namely:

**Theorem 4.** Given $G(O_S)$ as above and a scale factor $r_1$, there exists a polynomial $f$ and a scale factor $r_2$ such that if $\Sigma \subseteq G$ is a coarse $n$-manifold of scale $r_1$, with $\partial \Sigma \subseteq G(O_S)$, and $n < |S|$, then there is a coarse $n$-manifold $\Sigma' \subseteq G(O_S)$ of scale $r_2$, with the same topological type as $\Sigma$, and such that $\partial \Sigma' = \partial \Sigma$ and $\text{vol}(\Sigma') \leq f(\text{vol}(\Sigma))$.

If $n = 1$, then $f$ can be taken to be linear.

If $K$ is the algebraic closure of $K$, then for any $v \in S$ we have $\text{rank}_{K_v} G \leq \text{rank}_K G$, and it is a consequence of $G$ being $K$-isotropic that $1 \leq \text{rank}_{K_v} G$ for all $v \in S$. (In other words, each simple factor of $G$ has positive Euclidean rank.) Therefore,

$$|S| \leq k(G, S) = \sum_{v \in S} \text{rank}_{K_v} G \leq |S| \text{rank}_K G$$

and the inequalities above are sharp.

Applying the argument above that Conjecture 2 implies Lubotzky–Mozes–Raghunathan (Theorem 1), we see that Theorem 4 implies Lubotzky–Mozes–Raghunathan for those arithmetic groups for which $|S| \geq 2$.

In higher dimensions—and similar to the reasoning above that Conjecture 2 implies Conjecture 3—Theorem 4 implies

**Corollary 5.** $G(O_S)$ satisfies a polynomial $m$-dimensional isoperimetric inequality when $m \leq |S| - 2$. In particular, the Dehn function of $G(O_S)$ is bounded above by a polynomial if $|S| \geq 3$.

0.7. Finiteness properties

One cannot inquire about the word metric of a group if the group in question is not finitely generated. Similarly, $m$-dimensional isoperimetric inequalities only make sense for groups that are of type $F_{m+1}$. Thus, in order for Theorem 1, Conjecture 3, and Corollary 5 to be well-posed, we need to know that $G(O_S)$ is of type $F_{|S|-1}$, and this is known to be true. Indeed, Raghunathan [16] proved that $G(O_S)$ is of type $F_n$ for all $n$ when $S$ consists of only archimedean places, Borel–Serre [4] established that $G(O_S)$ is of type $F_n$ for all $n$ when $K$ is a number field, and Bux–Köhler–Witzel [6] recently established that $G(O_S)$ is of type $F_{|S|-1}$ in the case when $K$ is a function field.

But while the finiteness properties of $G(O_S)$ that are needed for Theorem 1 and Corollary 5 to be well-posed are known—that $G(O_S)$ is of type $F_{|S|-1}$—our proof makes no use of these finiteness properties, not even of finite generation. Rather, the needed finiteness properties can be quickly derived as a corollary from Theorem 4.

We illustrate here a quick proof that Theorem 4 implies that $G(O_S)$ is of type $F_{|S|-1}$: Suppose $G(O_S)$ and $r_1 > 0$ are given. For $s > 0$ we let $R(s)$ be the simplicial complex formed by declaring $(k + 1)$-tuples of points in $G(O_S)$ to be a simplex if each pair of points in the $(k + 1)$-tuple are within distance $s$ of each other. Then $R(\infty)$ is contractible,
and the natural action of $G(O_S)$ on $R(\infty)$ has finite cell stabilizers. Let $m \leq |S| - 2$. Any $m$-sphere in $R(r_1)$ corresponds naturally to a coarse $m$-sphere in $G(O_S)$ of scale $r_1$, and Theorem 4 implies the existence of an $(m + 1)$-disk in $R(r_2)$ that fills that sphere. Thus $G(O_S)$ is of type $F_{|S|-1}$ by Brown’s criterion (see e.g. [9, Theorem 7.4.1]).

Notice that the proof in the previous paragraph does not use Theorem 4 in its fullest, as the volumes of the filling disks used in the proof are irrelevant.

Using a similar proof, Conjecture 2 would imply that $G(O_S)$ is of type $F_{|S| - 1}$ when $K$ is a function field. Thus, Conjecture 2 would imply the strongest possible finiteness result for $G(O_S)$ that is independent of whether the global field $K$ is a number field or a function field.

0.8. Solvable groups

Our proof of Theorem 4 proceeds by first studying the large scale geometry of certain solvable groups. We prove the following generalization of Gromov’s result that certain solvable Lie groups of the form $\mathbb{R}^{n-1} \rtimes \mathbb{R}^n$ satisfy a quadratic Dehn function if $n \geq 3$:

**Theorem 6.** Let $Q$ be a proper $K$-parabolic subgroup of $G$. Let $U_Q$ be the unipotent radical of $Q$ and let $A_Q$ be the maximal $K$-split torus in the center of a $K$-Levi subgroup of $Q$.

Given $r_1 > 0$, there exists $r_2 > 0$ and a polynomial $f$ such that any coarse $m$-sphere $\Sigma \subseteq (U_Q A_Q)(O_S)$ of scale $r_1$ can be realized as the boundary of a coarse $(m + 1)$-ball in $(U_Q A_Q)(O_S)$ of scale $r_2$ whose volume is bounded above by $f(\text{vol}(\Sigma))$ as long as $m \leq |S| - 2$.

In particular, $(U_Q A_Q)(O_S)$ is of type $F_{|S|-1}$ and satisfies a polynomial $m$-dimensional isoperimetric inequality if $m \leq |S| - 2$.

As a special case of the above proposition, if $G$ is $K$-split and $B$ is a $K$-defined Borel subgroup of $G$, then $U_B B = B$, so $B(O_S)$ is of type $F_{|S|-1}$. Thus, Theorem 6 generalizes “half” of Bux’s theorem [5]:

**Theorem 7.** Suppose $K$ is a function field, that $G$ is $K$-split, and that $B \leq G$ is a $K$-defined Borel subgroup. Then $B(O_S)$ is of type $F_{|S|-1}$ but not of type $F_{|S|}$.

Bux’s theorem is proved using piecewise linear Morse theory. It is the most prominent result in the mostly unexplored field of finiteness properties of solvable arithmetic groups over function fields.

Wortman [20] proves a converse to Theorem 6 by showing that $(U_Q A_Q)(O_S)$ is not of type $F_{|S|}$ if $K$ is a function field, and that $(U_Q A_Q)(O_S)$ has an exponential $(|S| - 1)$-dimensional Dehn function if $K$ is a number field, thus generalizing the “other half” of Bux’s theorem.
0.9. Outline of proof

The plan for our proof was motivated by the unpublished Abels–Margulis proof of the Lubotzky–Mozes–Raghunathan theorem.

Section 1 of this paper contains some preliminary material and notation, and Section 2 displays an example that readers can use to guide themselves through the proofs in this paper.

In Section 3 we state the precise version of reduction theory (Proposition 9) that we will use in our proof of Theorem 4. We give a proof of Proposition 9 in an appendix (Section 8). Aside from starting with the well-known result that there are finitely many equivalence classes of minimal $K$-parabolic subgroups of $G$ modulo $G(O_S)$, our proof is independent of the characteristic of $K$.

The proof of our main result, Theorem 4, follows quickly from reduction theory (Proposition 9) and Proposition 17 which states that “boundaries of parabolic regions” have nice filling properties. On a first reading, the reader may wish to read the statement of Proposition 17 from Section 5, along with Section 3, before proceeding to Section 6 for a short proof of our main result.

Section 4 contains a proof of our theorem on fillings in solvable arithmetic groups (Theorem 6), which is equivalently stated as Proposition 10. It is used in Section 5 to prove our result on filling in boundaries of parabolic regions (Proposition 17).

Section 7 contains a short proof that our main result implies the isoperimetric inequalities stated in Corollary 5.

1. Preliminaries

Let $K$, $O_S$, and $G$ be as above. Because $G$ is $K$-isotropic, it has a minimal $K$-parabolic subgroup $P$. Let $A$ be a maximal $K$-torus in $P$.

We denote the root system for $(G, A)$ by $\Phi$. A positive set $\Phi^+$ is defined by $P$. We let $\Delta \subseteq \Phi^+$ be the set of simple roots.

For $I \subseteq \Delta$, we let $[I] \subseteq \Phi$ be the linear combinations generated by $I$, and we let $\Phi(I)^+ = \Phi^+ - [I]$ and $[I]^+ = [I] \cap \Phi^+$.

If $\alpha \in \Phi$, we let $U_{(\alpha)}$ be the root group corresponding to $\alpha$. For any set $\Psi \subseteq \Phi^+$ that is closed under addition, we let $U_{\Psi}$ be the group $\prod_{\alpha \in \Psi} U_{(\alpha)}$. The topological group $\prod_{\alpha \in \Delta} U_{\Psi}(K_v)$ is naturally identified topologically—but not necessarily algebraically—with a product of topological vector spaces that we endow with a norm $\| \cdot \|$.

If $I \subseteq \Delta$, then we let $A_I$ be the connected component of the identity in $\bigcap_{\alpha \in I} \ker(\alpha)$. We let $Z_G(A_I)$ be the centralizer of $A_I$ in $G$ so that $Z_G(A_I) = M_I A_I$ where $M_I$ is a reductive $K$-group with $K$-anisotropic center. We denote by $P_I$ the parabolic group $U_{\Phi(I)^+} M_I A_I$. The Levi subgroup $M_I A_I$ normalizes the unipotent radical $U_{\Phi(I)^+}$, and elements of $A_I$ commute with those of $M_I$.

Note that if $\alpha \in \Delta$, then $P_{\Delta - \alpha}$ is a maximal proper $K$-parabolic subgroup of $G$, and that $P_\emptyset = P$. To ease notation a bit, we will also denote $U_{\Phi(\emptyset)^+} = U_{\Phi^+}$, $M_\emptyset$, and $A_\emptyset$ at times as $U$, $M$, and $A$ respectively.
In the remainder of this paper we denote the product over $S$ of local points of a $K$-group by “unbolding”, so that, for example,

$$G = \prod_{v \in S} G(K_v).$$

**The metric on $G$.** Suppose $S = \{v\}$. Let $Q$ be a minimal $K_v$-parabolic subgroup of $G$ with maximal $K_v$-torus $A_v$ and unipotent radical $U_v$. Then there is a compact set $B \subseteq G$ such that $U_v A_v B = G$ and thus the left-invariant metric on $U_v A_v$ is quasi-isometric to $G$.

It follows that $A_v$ with the restricted metric from $G$ is quasi-isometric to Euclidean space. Also, if $u \in U_v$ then there is some $L > 0$ such that

$$\left(\frac{1}{L}\right) \log(\|u\| + 1) \leq d(1, u) \leq L \log(\|u\| + 1).$$

The properties of the metric on $G$ that we will use in this paper are deduced from this paragraph after taking the product metric in the case when $|S| > 1$.

**Bruhat decomposition.** We let $W \subseteq G(K)$ be a set of coset representatives, including 1, for the Weyl group $N_G(A)/Z_G(A)$ where $N_G(A)$ is the normalizer of $A$ in $G$. Then $G(K)$ is a disjoint union $\bigsqcup_{w \in W} P(K)wP(K)$.

**Conjugation.** If $g, h \in G$ and $H \subseteq G$, then we denote $ghg^{-1}$ as $^g h$ and $gHg^{-1}$ as $^g H$.

**Bounds.** Throughout, we write $a = O(c)$ to mean that there is some constant $\kappa$ depending only on $G$ and $G(O_S)$ such that $a \leq \kappa c$.

### 2. An example to follow throughout

In this section we provide an example of an arithmetic group $G(O_S)$ that those less familiar with arithmetic groups may prefer to focus on while reading the rest of this paper. The example we provide is the arithmetic group $\text{SL}_3(\mathbb{Z}[1/p_1, \ldots, 1/p_k])$ where $p_1, \ldots, p_k$ are prime numbers. It is an example that is simple enough that most of this paper can be read with it in mind and without any knowledge of the general properties of semisimple groups, but it is complicated enough to illustrate all of the important features and techniques of our general proof.

Although we do provide explicit examples in this section of $K, G, G(O_S)$, etc., these examples are particular only to this section, and nowhere in the remainder of the paper is any part of our proof restricted to this particular example.

#### 2.1. Global field, valuations, and $S$-integers

For our example we take $K$ to be the field $\mathbb{Q}$ of rational numbers.

Let $v_\infty$ be the archimedean valuation on $\mathbb{Q}$. That is, $v_\infty$ endows $\mathbb{Q}$ with the restriction of the standard norm on the real numbers, and the completion $K_{v_\infty}$ is the field $\mathbb{R}$ of real numbers.

Given a prime number $p$, there is also a $p$-adic valuation on $\mathbb{Q}$, denoted $v_p$, whose completion yields the locally compact field $\mathbb{Q}_p$ of $p$-adic numbers. What is important to
know about the $p$-adic norm is that the norm of $p$ is less than 1, and hence the $p$-adic norm of $1/p$ is greater than 1.

The archimedean and $p$-adic valuations are the only valuations that exist for $\mathbb{Q}$ up to scale.

We can take for a set of valuations $S = \{v_\infty, v_{p_1}, \ldots, v_{p_k}\}$ where each $p_i$ is a distinct prime. Thus, $|S| = k + 1$.

The ring of $S$-integers $O_S$ in this example is the ring $\mathbb{Z}[1/p_1, \ldots, 1/p_k]$. Notice that this ring has as units the elements of $\mathbb{Q}$ whose numerators and denominators are products of the primes $p_1, \ldots, p_k$ and their negatives.

It is a good exercise to check that $\mathbb{Z}[1/p_1, \ldots, 1/p_k]$ embedded diagonally into the product $\mathbb{R} \times \mathbb{Q}_{p_1} \times \cdots \times \mathbb{Q}_{p_k}$ is a discrete and cocompact subring.

2.2. Simple group and resulting arithmetic group and semisimple Lie group

We take for our example of $G$ the group $SL_3(\mathbb{C})$ of $3 \times 3$ matrices with entries in $\mathbb{C}$ whose determinants equal 1.

In what follows, if $R$ is a subring of $\mathbb{C}$, then $G(R)$ is understood to be the group $SL_3(R)$. In particular, the algebraic closures of $\mathbb{R}$ and $\mathbb{Q}_p$ are isomorphic to $\mathbb{C}$, so we can consider $\mathbb{R}$ and $\mathbb{Q}_p$ to be subrings of $\mathbb{C}$ and then the Lie group $G$ is the product $SL_3(\mathbb{R}) \times SL_3(\mathbb{Q}_{p_1}) \times \cdots \times SL_3(\mathbb{Q}_{p_k})$.

The arithmetic group $G(O_S)$ in this example is $SL_3(\mathbb{Z}[1/p_1, \ldots, 1/p_k])$. Embedded diagonally into $G$, it is a discrete subgroup.

More generally, we regard elements of $G(\mathbb{Q}) = SL_3(\mathbb{Q})$ as elements of $G$ via the diagonal embedding.

The number $\text{rank}_{\mathbb{Q}} SL_3(\mathbb{C})$ is the maximal dimension of a subgroup of $SL_3(\mathbb{C})$ that is diagonal after being conjugated by an element of $SL_3(\mathbb{R})$. Thus, $\text{rank}_{\mathbb{Q}} SL_3(\mathbb{C}) = 2$. Similarly, $\text{rank}_{\mathbb{Q}_p} SL_3(\mathbb{C}) = 2$ for any prime $p$, so for our choice of $G(O_S)$ we have $k(G, S) = \sum_{v \in S} \text{rank}_{K_v} SL_3(\mathbb{C}) = \sum_{v \in S} 2 = 2|S|$.

2.3. Roots

We let $P$ be the upper-triangular subgroup of $SL_3(\mathbb{C})$ whose entries below the diagonal all equal 0, and let $A$ be the 2-dimensional group of all diagonal matrices in $SL_3(\mathbb{C})$.

The choice of $P$ and $A$ provides us with the set of six roots $\Phi = \{\lambda_{ij} \mid 1 \leq i, j \leq 3 \text{ and } i \neq j\}$

where each $\lambda_{ij} : A \to \mathbb{C}^\times$ is defined by $\lambda_{ij}(a_1, a_2, a_3) = a_i/a_j$ if $(a_1, a_2, a_3) \in A$ is the matrix whose three diagonal entries are given by $a_1$, $a_2$, and $a_3$ respectively.

The operation of pointwise multiplication of roots is written additively, so that for example, $\lambda_{12} + \lambda_{23} = \lambda_{13}$ and $-\lambda_{ij} = \lambda_{ji}$. With this structure $\Phi = \{\lambda_{12}, \lambda_{23}, \lambda_{12} + \lambda_{23}, -\lambda_{12}, -\lambda_{23}, -\lambda_{12} - \lambda_{23}\}$.
The set of positive roots (consistent with our choice of $P$) is
\[ \Phi^+ = \{ \lambda_{12}, \lambda_{23}, \lambda_{12} + \lambda_{23} \} \]
and the set of simple roots is
\[ \Delta = \{ \lambda_{12}, \lambda_{23} \} . \]
The “highest root” is $\lambda_{13} = \lambda_{12} + \lambda_{23}$.

2.4. Subgroups of $G$ defined by roots

The group $A_{\{\lambda_{12}\}} \leq A$ is given by the group of diagonal matrices $(a_1, a_2, a_3)$ where $a_1 = a_2$. The group $A_{\{\lambda_{23}\}} \leq A$ is given by the group of diagonal matrices $(a_1, a_2, a_3)$ where $a_2 = a_3$. The group $A_{\emptyset}$ equals $A$.

Notice that the multiplicative group $A_{\{\lambda_{12}\}}(O_S)$ is virtually isomorphic to $\mathbb{Z}^k$, as is $A_{\{\lambda_{23}\}}(O_S)$. The group $A(O_S)$ is virtually isomorphic to $\mathbb{Z}^{2k}$.

The group $M_{\{\lambda_{12}\}} \cong \text{SL}_2(\mathbb{C})$ is the set of matrices in $\text{SL}_3(\mathbb{C})$ that can be written in the form
\[
\begin{pmatrix}
* & * & 0 \\
* & * & 0 \\
0 & 0 & 1
\end{pmatrix} .
\]
The group $M_{\{\lambda_{23}\}} \cong \text{SL}_2(\mathbb{C})$ consists of all matrices in $\text{SL}_3(\mathbb{C})$ that can be written in the form
\[
\begin{pmatrix}
1 & 0 & 0 \\
0 & * & * \\
0 & * & *
\end{pmatrix} .
\]
The group $M = M_{\emptyset}$ is trivial. For $I \subseteq \Delta$, elements of $M_I$ commute with elements of $A_I$.

For any $\lambda_{ij} \in \Phi$, the root group $U_{(\lambda_{ij})}$ is the subgroup of $\text{SL}_3(\mathbb{C})$ that equals the identity matrix in every entry except for perhaps the entry in the $i$-th row and $j$-th column. Notice that if $u \in U_{(\lambda_{ij})}$ and $a \in A$ then $aua^{-1} = \lambda_{ij}(a)u$.

Notice that $U_{(\lambda_{ij})}(\mathbb{R})$ is isomorphic to the additive group $\mathbb{R}$, and thus $U_{(\lambda_{ij})}(\mathbb{R})$ has a natural structure of a normed 1-dimensional vector space with an obvious choice of norm. Likewise $U_{(\lambda_{ij})}(\mathbb{Q}_p)$ is isomorphic to the normed vector space $\mathbb{Q}_p$. The group $U_{(\lambda_{ij})}$ is isomorphic to the product $\mathbb{R} \times \mathbb{Q}_p \times \cdots \times \mathbb{Q}_p$.

Following the notation from the previous section, we have $\Phi((\lambda_{12}))^+ = \{ \lambda_{13}, \lambda_{23} \}$, $\Phi((\lambda_{23}))^+ = \{ \lambda_{12}, \lambda_{13} \}$, and $\Phi(\emptyset)^+ = \{ \lambda_{12}, \lambda_{13}, \lambda_{23} \}$. From this, and the fact that for $I \subseteq \Delta$ the group $U_{\Phi(I)^+}$ is simply the product of those $U_{(\lambda_{ij})}$ with $\lambda_{ij} \in \Phi(I)^+$, one can easily see that each $U_{\Phi(I)^+}$ has the topological structure of a product of normed vector spaces (each of dimension 2 or 3 depending on the cardinality of $I$) and we endow each $U_{\Phi(I)^+}$ with a norm that we denote simply as $\| \cdot \|$, ignoring the set $I$ in our notation for the norm. The group structure on $U_{\Phi(I)^+}$ is also of a product of vector spaces if $I = \{ \lambda_{12} \}$ or if $I = \{ \lambda_{23} \}$. If $I = \emptyset$ then the group structure on $U = U_{\Phi(\emptyset)^+}$ is nilpotent, but not abelian.
It is easy to form explicitly the parabolic groups $P_I = U_{\Phi_I} \cdot M_I A_I$ for $I \subseteq \Delta$. The group $P_{\{\lambda_{12}\}}$ is the set of matrices in $SL_3(\mathbb{C})$ of the form

$$\begin{pmatrix} * & * & * \\ * & * & * \\ 0 & 0 & * \end{pmatrix} = \begin{pmatrix} 1 & 0 & * \\ 0 & 1 & * \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} a_1 & 0 & 0 \\ 0 & a_1 & 0 \\ 0 & 0 & a_1^{-2} \end{pmatrix}.$$

Elements of $P_{\{\lambda_{23}\}}$ have the form

$$\begin{pmatrix} * & * & * \\ 0 & * & * \\ 0 & * & * \end{pmatrix}$$

and elements of $P = P_{\emptyset}$ have the form

$$\begin{pmatrix} * & * & * \\ 0 & * & * \\ 0 & 0 & * \end{pmatrix}.$$

It is easy to check that $U_{\Phi_I}$ is a normal subgroup of $P_I$.

There is an automorphism of $SL_3(\mathbb{C})$ that restricts to an isomorphism between $P_{\{\lambda_{12}\}}$ and $P_{\{\lambda_{23}\}}$. Much of the proof in this paper is considered by examining parabolic groups (or spaces associated with them) in the different cases enumerated by proper subsets $I \subseteq \Delta$. Thus, when considering our proof as it applies to the particular example from this section, one can often restrict to just two cases: $I = \{\lambda_{12}\}$ and $I = \emptyset$.

2.5. Parabolic regions

In the next section, “parabolic regions” will be defined. They will be denoted as $R_I$ for $I \subseteq \Delta$.

Very nearly, $R_I$ is the space

$$P_I(\mathbb{Z}[1/p_1, \ldots, 1/p_k]) A_I^+$$

or equivalently

$$U_{\Phi_I}(\mathbb{Z}[1/p_1, \ldots, 1/p_k]) M_I(\mathbb{Z}[1/p_1, \ldots, 1/p_k]) A_I^+$$

where $A_I^+$ is defined in the next section as those $a \in A$ such that $a$ commutes with elements of $M_I(\mathbb{Z}[1/p_1, \ldots, 1/p_k])$ and such that, up to multiplying $a$ by an element of $A(\mathbb{Z}[1/p_1, \ldots, 1/p_k])$, $\|a^{-1}ua\| \leq \|u\|$ for any $u \in U_{\Phi_I}(\mathbb{Z}[1/p_1, \ldots, 1/p_k]) \leq U_{\Phi_I}$.

Since $U_{\Phi_I}(\mathbb{Z}[1/p_1, \ldots, 1/p_k])$ is a cocompact lattice in $U_{\Phi_I}$, and because we are only interested in the large scale geometry of $R_I$, the actual definition of a parabolic region that we will use is

$$R_I = U_{\Phi_I} M_I(\mathbb{Z}[1/p_1, \ldots, 1/p_k]) A_I^+.$$

We make this substitution only to ease notation a bit.
2.6. Weyl group and cusps

We let $W \subseteq \text{SL}_3(\mathbb{C})$ be the set of six matrices that permute the standard coordinate vectors $e_1, e_2, e_3 \in \mathbb{C}^3$. The elements of $W$ normalize $A$, and they are representatives for the Weyl group which is defined as the normalizer of $A$ modulo $A$.

The “longest element” of the Weyl group is represented by the transposition that interchanges $e_1$ and $e_3$ and fixes $e_2$.

The set $F$ from Theorem 8 below as it applies to the example illustrated in this section consists of only the identity element. That is, the double coset space

$$\text{SL}_3(\mathbb{Z}[1/p_1, \ldots, 1/p_k]) \backslash \text{SL}_3(\mathbb{Q}) / \mathcal{P}(\mathbb{Q})$$

is a single point. Indeed, it is well known that

$$\text{SL}_3(\mathbb{Z}) \backslash \text{SL}_3(\mathbb{Q}) / \mathcal{P}(\mathbb{Q})$$

is a single point, as this is equivalent to the assertion that $\text{SL}_3(\mathbb{Z})$ acts transitively on complete flags in $\mathbb{Q}^3$.

2.7. End of example

We have now concluded our example, and in the remainder of the paper we will return to our more general notation where $K$ is an arbitrary global field, $G$ is an arbitrary non-commutative, absolutely almost simple, $K$-isotropic $K$-group, $\mathcal{P}$ is an arbitrary minimal $K$-parabolic subgroup of $G$, and so on.

3. Parabolic regions and the pruning of $G$ to $G(\mathcal{O}_S)$

This section contains the precise statement from reduction theory that our proof requires. We begin by recalling the “finiteness of cusps” theorem from reduction theory.

**Theorem 8.** There exists a finite set $F \subseteq G(K)$ of coset representatives for $G(\mathcal{O}_S) \backslash G(K) / \mathcal{P}(K)$.

**Proof.** Restriction of scalars applied to Proposition 15.6 of Borel’s book [3] on arithmetic groups gives the result when $\mathcal{O}_S$ is the ring of integers in a number field. The general case for number fields is immediate since any ring of $S$-integers contains the ring of integers.

When $K$ is a function field, this theorem is Behr’s [1, Satz 8]. Behr’s proof needs a technical hypothesis (used for [1, Satz 5]). However, Harder has removed the need for that hypothesis: [12, Korollar 2.2.7] can be used as a replacement for [1, Satz 5] in the proof. \qed
3.1. Parabolic regions

If \( Q \) is a proper \( K \)-parabolic subgroup of \( G \), then \( Q \) is conjugate over \( G(K) \) to \( P_I \) for some proper subset \( I \subseteq \Delta \). We let

\[
\Lambda_Q = \{ \gamma f \in G(O_S)F \mid \gamma f P_I = Q \text{ for some } I \subseteq \Delta \}
\]

where \( F \) is as in Theorem 8. Notice that Theorem 8 ensures that \( \Lambda_Q \) is nonempty.

Given any \( a = (a_v)_{v \in S} \in A \), and any \( \alpha \in \Phi \), we let

\[
|\alpha(a)| = \prod_{v \in S} |\alpha(a_v)|_v
\]

where \( |\cdot|_v \) is the \( v \)-adic norm on \( K_v \).

Given any \( t > 0 \) and any \( I \subseteq \Delta \) we let

\[
A_I^+(t) = \{ a \in A_I \mid |\alpha(a)| \geq t \text{ if } \alpha \in \Delta - I \}
\]

and we let \( A_I^+(t) = A_I^+(1) \).

For \( t > 0 \), we let

\[
R_Q(t) = \Lambda_Q U_{\Phi(I)} \cdot M_I(O_S) A_I^+(t).
\]

We call any such subset of \( G \) a parabolic region. We set \( R_Q = R_Q(1) \).

**Boundaries of parabolic regions.** We let \( \partial A_I^+(t) \) be the set of all \( a \in A_I(t) \) such that there exists \( \alpha \in \Delta - I \) with \( |\alpha(a)| \leq |\alpha(b)| \) for all \( b \in A_I(t) \). Then we define the boundary of a parabolic region as

\[
\partial R_Q(t) = \Lambda_Q U_{\Phi(I)} \cdot M_I(O_S) \partial A_I^+(t).
\]

3.2. Pruning \( G \) to \( G(O_S) \)

Given \( 0 \leq n < |\Delta| \), we let \( \mathcal{P}(n) \) be the set of \( K \)-parabolic subgroups of \( G \) that are conjugate over \( G(K) \) to some \( P_I \) with \( |I| = n \).

We will directly apply the following result from reduction theory to our proof of Theorem 4.

**Proposition 9.** There exists a bounded set \( B_0 \subseteq G \), and given a bounded set \( B_n \subseteq G \) and any \( N_n \geq 0 \) for \( 0 \leq n < |\Delta| \), there exists \( t_n > 1 \) and a bounded set \( B_{n+1} \subseteq G \) such that

(i) \( G = \bigcup_{Q \in \mathcal{P}(0)} R_Q B_0 \);
(ii) if \( Q, Q' \in \mathcal{P}(n) \) and \( Q \neq Q' \), then the distance between \( R_Q(t_n) B_n \) and \( R_{Q'}(t_n) B_n \) is at least \( N_n \);
(iii) \( G(O_S) \cap R_Q(t_n) B_n = \emptyset \) for all \( n \);
(iv) if \( n \leq |\Delta| - 2 \) then \( \bigcup_{Q \in \mathcal{P}(n)} R_Q B_n = \bigcup_{Q \in \mathcal{P}(n+1)} R_Q B_{n+1} \).
(v) \( \bigcup_{Q \in \mathcal{P}(|\Delta|-1)} R_Q B_{|\Delta|-1} \) is contained in \( G(\mathcal{O}_S) B_{|\Delta|-1} \); and

(vi) if \( Q \in \mathcal{P}(n) \), then there is an \((L, C)\) quasi-isometry \( R_Q(t_n) B_n \to U_{\Phi(I)^+} M_I(\mathcal{O}_S) A_I^+ \) for some \( I \subseteq \Delta \) with \(|I| = n\). The quasi-isometry restricts to an \((L, C)\) quasi-isometry \( \partial R_Q(t_n) B_n \to U_{\Phi(I)^+} M_I(\mathcal{O}_S) \partial A_I^+ \) where \( L \geq 1 \) and \( C \geq 0 \) are independent of \( Q \).

Proposition 9 can be deduced from the Borel–Harish-Chandra–Behr–Harder reduction theory. The case when \( K \) is a number field can be deduced from work of Borel ([3] and [2]) and the case when \( K \) is a function field can be shown using Harder’s work [12].

In the appendix (Section 8), we give a more unified proof of Proposition 9.

4. Filling spheres in solvable groups

In this section we will prove

**Proposition 10.** Let \( I \subseteq \Delta, 0 < n \leq |S| - 2 \), and \( r > 0 \). There are \( m \in \mathbb{N} \) and \( r' > 0 \) such that if \( \Sigma \) is an \( r \)-coarse \( n \)-sphere in \( U_{\Phi(I)^+} A_I(\mathcal{O}_S) \), then there is an \( r' \)-coarse \((n + 1)\)-ball in \( U_{\Phi(I)^+} A_I(\mathcal{O}_S) \) whose volume is \( O(\text{vol}(\Sigma)^m) \) and whose boundary is \( \Sigma \).

Proposition 10 will be used to prove Proposition 17 in the next section. Our proof of Proposition 10 is motivated by a proof of Gromov’s that certain solvable Lie groups have simply connected asymptotic cones ([11, 2.B.f]).

4.1. Reducing to cells in slices

Before the next lemma, we need a couple of definitions.

Given a coarse manifold \( \Sigma \) that is the image under a function \( f \) of the vertices of a triangulated manifold \( M \), a coarse (polysimplicial) subdivision of \( \Sigma \) is an extension of \( f \) to the vertices of a (polysimplicial) subdivision of \( M \).

A \( k \)-slice in \( U_{\Phi(I)^+} A_I(\mathcal{O}_S) \) is a left coset of

\[
\left[ \prod_{v \in S'} U_{\Phi(I)^+}(K_v) \right] A_I(\mathcal{O}_S)
\]

for some \( S' \subseteq S \) with \(|S'| = k\).

**Lemma 11.** Given \( r > 0 \) and \( n \in \mathbb{N} \), there is some \( r' > 0 \) such that any coarse \( n \)-sphere \( \Sigma \subseteq U_{\Phi(I)^+} A_I(\mathcal{O}_S) \) of scale \( r \) can be subdivided into a coarse polysimplicial \( n \)-sphere \( \Sigma' \) of scale \( r' \) such that every coarse \( k \)-cell in \( \Sigma' \) is contained in a \( k \)-slice, and such that \( \text{vol}(\Sigma') = O(\text{vol}(\Sigma)) \).

**Proof.** Let \( \pi_v : U_{\Phi(I)^+} A_I(\mathcal{O}_S) \to U_{\Phi(I)^+}(K_v) \) and \( \pi_A : U_{\Phi(I)^+} A_I(\mathcal{O}_S) \to A_I(\mathcal{O}_S) \) be the obvious projection maps.
Let $\sigma \subseteq \Sigma$ be a $k$-simplex and let $x_1, \ldots, x_{k+1}$ be its vertices. For each $v \in S$, we form an abstract $k$-simplex with vertices $\pi_v(x_1), \ldots, \pi_v(x_{k+1})$. Call this simplex $Z_{\sigma,v}$. Let $Z_{\sigma,A}$ be the abstract $k$-simplex with vertices $\pi_A(x_1), \ldots, \pi_A(x_{k+1})$.

Let

$$Z_\sigma = \left( \prod_{v \in \Sigma} Z_{\sigma,v} \right) \times Z_{\sigma,A}. \text{ Notice that } Z_\sigma \text{ is a polysimplicial complex that is homeomorphic to a } (|S| + 1)k\text{-ball, and that the number of cells in } Z_\sigma \text{ is bounded by a constant depending only on } k \text{ and } |S|. \text{ There is also an obvious function from the vertices of } Z_\sigma \text{ into } U_{\Phi(I)} + A_I(\mathcal{O}_S), \text{ which we will denote as } h. \text{ Because } \Sigma \text{ has scale } r, \text{ there is some } r' > 0 \text{ depending only on } r \text{ and } n \text{ such that if } u \text{ and } w \text{ are vertices in } Z_\sigma, \text{ then the distance between } h(u) \text{ and } h(w) \text{ is at most } r'. \text{ Thus, the vertices of any } k\text{-cell in } Z_\sigma \text{ maps via } h \text{ to a coarse } k\text{-cell in } U_{\Phi(I)} + A_I(\mathcal{O}_S) \text{ of diameter at most } r'. \text{ Furthermore, any such coarse } k\text{-cell must be contained in a } k\text{-slice, since it projects to a positive-dimensional simplicial in at most } k \text{ of the } Z_{\sigma,v} \text{ factors.} \text{ Vertices of } \Sigma \text{ are clearly contained in } 0\text{-slices. Suppose } \sigma \subseteq \Sigma \text{ is a coarse } 1\text{-simplex. Its faces—that is, its endpoints—are represented by vertices in } Z_\sigma. \text{ Connect them to a path } \tilde{\sigma} \text{ in the } 1\text{-skeleton of } Z_\sigma. \text{ Since the number of edges in } Z_\sigma \text{ is bounded, } \tilde{\sigma} \text{ consists of a bounded number of edges. Map the vertices of } \tilde{\sigma} \text{ into } U_{\Phi(I)} + A_I(\mathcal{O}_S) \text{ via } h, \text{ and we have subdivided } \sigma \text{ into a uniformly bounded number of coarse } 1\text{-polysimplices of scale } r' \text{ such that each coarse } 1\text{-polysimplex is contained in a } 1\text{-slice.} \text{ We continue by induction.} \text{ Let } \sigma \text{ now be a coarse } k\text{-simplex in } \Sigma. \text{ By induction hypothesis we may assume that the faces of } \sigma, \text{ named } \tau_1, \ldots, \tau_{k+1}, \text{ have been subdivided into coarse } (k-1)\text{-polysimplices of scale } r' \text{ that are contained in } (k-1)\text{-slices.} \text{ The subdivided } \tau_i \text{ are represented by complexes } \tilde{\tau}_i \subseteq Z_{\sigma}. \text{ Since } \tau_i \subseteq \sigma, \text{ we have } Z_{\tau_i} \subseteq Z_{\sigma}, \text{ and } \bigcup_i \tilde{\tau}_i \subseteq Z_{\sigma} \text{ is the continuous image of a } (k-1)\text{-sphere.} \text{ Because } Z_\sigma \text{ has a uniformly bounded number of polysimplices, there is a topological } k\text{-ball } \tilde{\sigma} \subseteq Z_{\sigma} \text{ whose boundary is } \bigcup_i \tilde{\tau}_i \subseteq Z_{\sigma} \text{ and such that via } h, \text{ the vertices of } \tilde{\sigma} \text{ represent a coarse polysimplicial } k\text{-ball of scale } r' \text{ in } U_{\Phi(I)} + A_I(\mathcal{O}_S), \text{ whose volume is bounded by a constant depending on } n \text{ and } |S|, \text{ and such that each coarse } k\text{-polysimplex in the coarse ball is contained in a } k\text{-slice.} \text{ The result is a coarse polysimplicial subdivision of } \Sigma \text{ all of whose coarse } k\text{-polysimplices are contained in } k\text{-slices.} \text{ □} \text{ 4.2. The geometry of slices} \text{ The convenience of reducing the problem of filling spheres in } U_{\Phi(I)} + A_I(\mathcal{O}_S) \text{ to filling spheres in } k\text{-slices of } U_{\Phi(I)} + A_I(\mathcal{O}_S) \text{ is that } k\text{-slices are negatively curved in some sense. Our proof of Lemma 13 makes these remarks more precise, but first we will need} \text{ Lemma 12. If } I \subseteq \Delta \text{ and } S' \text{ is a proper subset of } S, \text{ then the projection of } A_I(\mathcal{O}_S) \text{ into } \prod_{v \in S'} A_I(K_v) \text{ is a finite Hausdorff distance from } \prod_{v \in S'} A_I(K_v).
Proof. It suffices to prove the lemma when \( S' = S - \{w\} \) for some \( w \in S \).

Notice that the geometric dimension of \( A_f(\mathcal{O}_S) \) equals \( (|S| - 1)(|\Delta - I|) \) (by Dirichlet’s units theorem), as does \( \prod_{i \in S'} A_f(K_v) \). So it suffices to check that the kernel of the projection \( A_f(\mathcal{O}_S) \to \prod_{i \in S'} A_f(K_v) \) is bounded. But if \( a \in A_f(\mathcal{O}_S) \) is trivial in \( A_f(K_v) \) for each \( v \in S' \), then by the product formula, \( a \) has trivial norm in \( A_f(K_w) \), and thus \( a \) is bounded in \( A_f \). \( \square \)

Lemma 13. Let \( I \subseteq \Delta \), let \( k < |S| \), and let \( n, r \geq 0 \). Then there is some \( r' > 0 \) such that any coarse polysimplicial \( n \)-sphere \( \Sigma \) of scale \( r \) that is contained in a \( k \)-slice of \( U_{\Phi(I)^+} A_f(\mathcal{O}_S) \) bounds a coarse polysimplicial \((n + 1)\)-ball, denoted \( D \), which is of scale \( r' \) and is contained in the same \( k \)-slice with \( \text{vol}(D) = O(\text{diam}(\Sigma)^{n+1} + \text{vol}(\Sigma)\text{diam}(\Sigma)) \).

Proof. After left translation, we may assume

\[
1 \in \Sigma \subseteq \prod_{v \in S'} U_{\Phi(I)^+}(K_v)A_f(\mathcal{O}_S)
\]

where \( |S'| = k \).

Let \( L \) be the diameter of \( \Sigma \), and choose \( u \in \prod_{v \in S'} U_{\Phi(I)^+}(K_v) \) and \( a \in A_f(\mathcal{O}_S) \) such that \( |a\alpha| < L \) and \( |u| = O(e^L) \).

By the previous lemma, there is some \( b \in A_f(\mathcal{O}_S) \) such that \( |\alpha(b)| < 1 \) for all \( \alpha \in \Delta - I \) and \( v \in S' \). Therefore, \( \beta(b)|_v < 1 \) for all \( \beta \in \Phi(I)^+ \) and \( v \in S' \). The choice of \( b \) depends on \( S' \) and is independent of \( \Sigma \).

Notice that for \( N = O(L) \), \( d(ab^N, uab^N) = d(1, b^{-N}(a^{-1}ua)b^N) \leq 1 \). Thus, we may assume that \( \Sigma b^N \) is contained in \( A_f(\mathcal{O}_S) \), which is quasi-isometric to Euclidean space and thus there is an \( r \)-coarse polysimplicial ball \( D' \subseteq A_f(\mathcal{O}_S) \) whose volume is \( O(L^{n+1}) \) and whose boundary is \( \Sigma b^N \). Therefore, we can let

\[
D = D' \cup \bigcup_{i=0}^{N} \Sigma b^N.
\]

Notice that the volume of a coarse 0 sphere equals 2, and if \( n > 0 \), then the diameter of an \( r \)-coarse \( n \)-sphere is bounded by \( r(\text{vol}(\Sigma)) \). Thus from Lemma 13 we have the following two corollaries.

Corollary 14. Let \( I \subseteq \Delta \), let \( k < |S| \). Then there is some \( r' > 0 \) such that if \( x \) and \( y \) are any two points in a \( k \)-slice of \( U_{\Phi(I)^+} A_f(\mathcal{O}_S) \), then \( x \) and \( y \) are the endpoints of an \( r' \)-coarse path whose volume (or length) is \( O(d(x, y)) \).

Corollary 15. Let \( I \subseteq \Delta \), and let \( k < |S| \), and let \( n, r > 0 \). Then there is some \( r' > 0 \) such that any coarse polysimplicial \( n \)-sphere of scale \( r \) contained in a \( k \)-slice of \( U_{\Phi(I)^+} A_f(\mathcal{O}_S) \) bounds a coarse polysimplicial \((n + 1)\)-ball of scale \( r' \) in the same \( k \)-slice with \( \text{vol}(D) = O(\text{vol}(\Sigma)^{n+1}) \).
4.3. Filling spheres that are piecewise in slices

We use the negative curvature of \( k \)-slices to prove

**Lemma 16.** For \( r > 0 \) and \( n \leq |S| - 2 \), there are \( m \in \mathbb{N} \) and \( r' > 0 \) such that if \( \Sigma \subseteq U_{\Phi(I)^+}A_I(O_S) \) is an \( r \)-coarse polysimplicial \( n \)-sphere all of whose coarse \( k \)-cells are contained in \( k \)-slices (for all \( k \leq n \)), then there is an \( r' \)-coarse polysimplicial \((n+1)\)-ball \( D \) such that \( \partial D = \Sigma \) and \( \text{vol}(D) = O(\text{vol}(\Sigma)^m) \).

**Proof.** We may assume that \( 1 \in \Sigma \).

Fix \( w \in S \) and let
\[
\pi : U_{\Phi(I)^+}A_I(O_S) \to \left[ \prod_{v \in (S-w)} U_{\Phi(I)^+}(K_v) \right] A_I(O_S)
\]
be the obvious projection onto the \((|S| - 1)\)-slice.

Let
\[
D' \subseteq \prod_{v \in S-w} U_{\Phi(I)^+}(K_v)A_I(O_S)
\]
be the coarse polysimplicial \((n+1)\)-ball with \( \partial D' = \pi(\Sigma) \) that is given by Corollary 15.

If \( x \) is a vertex in \( \Sigma \), then by Corollary 14 we can connect \( x \) to \( \pi(x) \) with a coarse path of length \( O(\text{vol}(\Sigma)) \) contained in the 1-slice that is the coset of \( U_{\Phi(I)^+}(K_w)A_I(O_S) \) containing \( x \) and \( \pi(x) \). Call this path \( p_x \).

Given a coarse 1-cell \( \sigma \subseteq \Sigma \) with endpoints \( x_1 \) and \( x_2 \), notice that
\[
\sigma \cup \pi(\sigma) \cup p_{x_2} \cup p_{x_1}
\]
is a coarse loop contained in a 2-slice, since \( \sigma \) is contained in a 1-slice. Therefore, by Corollary 15 there is a coarse polysimplicial 2-disk \( D_\sigma \) contained in the 2-slice whose volume is \( O(\text{vol}(\Sigma)^2) \) and whose boundary is the loop above.

We continue by induction. If \( \sigma \subseteq \Sigma \) is a coarse \( k \)-cell with faces \( \tau_1, \ldots, \tau_m \), then
\[
\sigma \cup \pi(\sigma) \cup \bigcup_{i=1}^m D_{\tau_i}
\]
is a coarse polysimplicial \( k \)-sphere contained in a \((k+1)\)-slice. Since \( k \leq n \), we have \( k + 1 \leq |S| - 1 \), and thus by Corollary 15, there is a coarse polysimplicial \((k+1)\)-disk \( D_\sigma \) contained in the \((k+1)\)-slice whose volume is polynomial in \( \text{vol}(\Sigma) \), and whose boundary is the above coarse polysimplicial \( k \)-sphere.

Let \( C \) be the set of all \( n \)-cells in \( \Sigma \). Then
\[
D = D' \cup \bigcup_{\sigma \in C} D_\sigma
\]
satisfies the lemma. \( \Box \)
Proof of Proposition 10.} Subdivide $\Sigma$ to $\Sigma'$ using Lemma 11. Then $\Sigma'$ bounds a coarse polysimplicial ball $D$ by Lemma 16.

Since the Hausdorff distance between $\Sigma$ and $\Sigma'$ is bounded, we may use $D$ and the quasi-isometry from $G$ to its associated product of symmetric spaces and Euclidean buildings to realize the desired coarse $(n+1)$-ball in $U_{\Phi(I)^+}A_I(O_S)$.

Proof of Theorem 6. The theorem follows immediately from Proposition 10. Indeed, we may assume that $Q = P_I$ for some proper subset $I \subseteq \Delta$. Thus, $U_Q = U_{\Phi(I)^+}$, any $K$-Levi subgroup of $P_I$ is conjugate over $P_I(K)$ to $M_I A_I$, and the maximal $K$-split torus of the center of $M_I A_I$ is $A_I$. Furthermore, since $U_{\Phi(I)^+}$ is unipotent, $U_{\Phi(I)^+}(O_S)$ is a cocompact lattice in, and thus is quasi-isometric to, $U_{\Phi(I)^+}$.

5. Filling manifolds in the boundaries of parabolic regions

For a proper subset $I \subseteq \Delta$, we let $A_I^+ = A_I^+(1)$, $R_I = U_{\Phi(I)^+} M_I(O_S) A_I^+$, and $\partial R_I = U_{\Phi(I)^+} M_I(O_S) \partial A_I^+$.

In this section we use Proposition 10 to prove that a coarse manifold in the boundary of a parabolic region has a polynomially efficient filling in the same boundary. The precise statement is given as

**Proposition 17.** There is some $m \in \mathbb{N}$, and given $r > 0$, there is some $r' > 0$ such that the following holds:

If $n \leq |S| - 1$ and $\Sigma \subseteq R_I$ is an $r$-coarse $n$-manifold whose volume and maximum distance from 1 are bounded by $d > 0$, and whose boundary components are contained in $\partial R_I$, then there is an $r'$-coarse $n$-manifold $\Sigma' \subseteq \partial R_I$ of the same topological type as $\Sigma$, with $\partial \Sigma' = \partial \Sigma$ and

$$\text{vol}(\Sigma') = O(d^m).$$

**Proof.** The quotient map

$$R_I \to M_I(O_S) A_I^+$$

is distance nonincreasing.

Choose a Lipschitz map $A_I^+ \to \partial A_I^+$ that is the identity on $\partial A_I^+$. Because $M_I$ and $A_I$ commute, $M_I(O_S) A_I^+$ is a metric direct product, the induced map

$$M_I(O_S) A_I^+ \to M_I(O_S) \partial A_I^+$$

is Lipschitz.

We define $q_I$ to be the composition

$$R_I \to M_I(O_S) A_I^+ \to M_I(O_S) \partial A_I^+$$

so that $q_I$ is Lipschitz, and takes values in $\partial R_I$.

Suppose $x_i \in \partial \Sigma$. Then $x_i = u_i m_i a_i$ for some $u_i \in U_{\Phi(I)^+}$, $m_i \in M_I(O_S)$, and $a_i \in \partial A_I^+$. 

Given \( i \), choose \( w \in S \), and let \( u_w \in U_{\Phi(I)^+}(K_w) \) and \( u_{-w} \in \prod_{v \in S - w} U_{\Phi(I)^+}(K_v) \) be such that \( u_w - u_{-w} = (m_i a_i)^{-1} u_i m_j a_i \).

By Corollary 14, there is a coarse path \( f_w \subseteq U_{\Phi(I)^+}(K_w)A_f(O(S)) \) of length \( O(d) \) whose endpoints are 1 and \( u_w \). By the same corollary, there is a coarse path \( f_{-w} \subseteq \prod_{v \in S - w} U_{\Phi(I)^+}(K_v)A_f(O(S)) \) of length \( O(d) \) whose endpoints are 1 and \( u_{-w} \). We let \( f_i \subseteq U_{\Phi(I)^+}A_f(O(S)) \) be the union of \( f_w \) and \( u_{w} f_{-w} \), so that \( f_i \) is a coarse path from 1 to \( (m_i a_i)^{-1} u_i m_j a_i \) whose length is \( O(d) \).

Thus,

\[
\begin{align*}
m_i a_i f_i &\subseteq m_i a_i U_{\Phi(I)^+} A_f(O(S)) \subseteq U_{\Phi(I)^+} m_i a_i A_f(O(S)) \subseteq U_{\Phi(I)^+} m_i \partial A_f^+ \\
&\subseteq U_{\Phi(I)^+} M_f(O(S)) \partial A_f^+ \subseteq \partial R_f
\end{align*}
\]

is a path of length \( O(d) \) that connects \( m_i a_i = q_f(x_i) \) to \( u_i m_j a_i = x_i \). We name this path \( D(x_i) \).

In the remainder of this proof, we will denote a coarse \( k \)-simplex in \( \partial \Sigma \) by the \((k+1)\)-tuple of its vertices.

We claim that for any coarse simplex \((x_1, \ldots, x_k)\) in \( \partial \Sigma \), there is a coarse \( k \)-disk \( D(x_1, \ldots, x_k) \) such that

(i) \( D(x_1, \ldots, x_k) \subseteq m_i a_i U_{\Phi(I)^+} A_f(O(S)) B_k \) for any \( 1 \leq i \leq k \) and some compact set \( B_k \subseteq G \) of radius depending on \( k \) with \( 1 \in B_k \).

(ii) \( \partial D(x_1, \ldots, x_k) \) is the union

\[
(x_1, \ldots, x_k) \cup q_f(x_1, \ldots, x_k) \cup \bigcup_{i=1}^{k} D(x_1, \ldots, \hat{x}_i, \ldots, x_k)
\]

where \((x_1, \ldots, \hat{x}_i, \ldots, x_k)\) denotes the simplex obtained by removing the vertex \( x_i \) from the simplex \((x_1, \ldots, x_k)\).

(iii) The volume of \( D(x_1, \ldots, x_k) \) is \( O(d^m) \) for some \( m \) depending on \( k \).

We prove our claim by induction on \( k \). The case when \( k = 1 \) is resolved, so we assume our claim is true for \( k \) and assume that \((x_1, \ldots, x_{k+1})\) is a coarse simplex in \( \partial \Sigma \).

Let \( s(x_1, \ldots, x_{k+1}) \) be the union of \((x_1, \ldots, x_k)\), \( q_f(x_1, \ldots, x_{k+1})\), and \( \bigcup_{i=1}^{k+1} D(x_1, \ldots, \hat{x}_i, \ldots, x_{k+1}) \). By the induction hypothesis, \( s(x_1, \ldots, x_{k+1}) \) is a coarse sphere of dimension \( k \leq |S| - 2 \).

If \( B \subseteq G \) is the ball of radius \( r \) around 1, and \( 1 \leq i, j \leq k+1 \), then \((m_i a_i)^{-1} m_j a_j \in B \) by our assumption on the scale of \( \Sigma \).

Recall that \( m_i, m_j \in M_f \), so they commute with \( A_f(O(S)) \) and normalize \( U_{\Phi(I)^+} \), as do \( a_i \) and \( a_j \). Thus,

\[
m_j a_j U_{\Phi(I)^+} A_f(O(S)) B_k = m_i a_i U_{\Phi(I)^+} A_f(O(S)) (m_i a_i)^{-1} m_j a_j B_k \subseteq m_i a_i U_{\Phi(I)^+} A_f(O(S)) B B_k.
\]

Therefore, we let \( B_{k+1} = B B_k \) so that \( s(x_1, \ldots, x_{k+1}) \subseteq m_i a_i U_{\Phi(I)^+} A_f(O(S)) B_{k+1} \) for any \( 1 \leq i \leq k + 1 \).
By Proposition 10, there is a coarse \((k + 1)-\)ball in \(m_1 a_1 U_{\Phi(I)} + A_I(\mathcal{O}_S)B_{k+1}\) whose boundary is \(s(x_1, \ldots, x_{k+1}),\) and whose volume is bounded by a polynomial in the volume of \(s(x_1, \ldots, x_{k+1}).\) We name this ball \(D(x_1, \ldots, x_{k+1}).\) This justifies our claim.

Now let \(X\) be the union of \(D(x_1, \ldots, x_n)\) taken over maximal simplices \((x_1, \ldots, x_n)\) in \(\partial \Sigma.\) Then \(X\) is a coarse \(n\)-manifold in

\[
\mathcal{M}_I(\mathcal{O}_S)(\partial A_I^+)U_{\Phi(I)} + A_I(\mathcal{O}_S)B_n \subseteq U_{\Phi(I)} + \mathcal{M}_I(\mathcal{O}_S)\partial A_I^+ B_n \subseteq \partial R IB_n.
\]

The volume of \(X\) is \(O(d^n)\) for some \(m,\) and the boundary of \(X\) is \(\partial \Sigma \cup q_I(\partial \Sigma).\) Notice that \(X\) establishes something like a “polynomial homotopy” between \(q_I\) restricted to \(\partial \Sigma\) and the identity map restricted to \(\partial \Sigma.

We let \(\Sigma'\) be the image of \(q_I(\Sigma) \cup X\) under the obvious rough isometry \(R IB_n \to R I.\)

\(\square\)

6. Proof of main result (Theorem 4)

Let \(B_0\) be as in Proposition 9 and let \(\Sigma \subseteq G = \bigcup_{Q \in \mathcal{P}(0)} R_0B_0\) be a coarse \(n\)-manifold of scale \(r_0\) with \(\partial \Sigma \subseteq \mathcal{G}(\mathcal{O}_S)\) and \(n < |\mathcal{S}|.\)

We relabel \(\Sigma\) as \(\Sigma_0,\) and we let \(N_0 = 2r_0.\) Then let \(B_1\) and \(t_0\) be as in Proposition 9.

For \(Q \in \mathcal{P}(0),\) we define the coarse manifolds

\[
\Sigma_{0,Q} = \Sigma_0 \cap R_0(t_0)B_0 \quad \text{and} \quad \Sigma_{0,\partial} = \Sigma_0 - \bigcup_{Q \in \mathcal{P}(0)} \Sigma_{0,Q}.
\]

Notice that \(\Sigma_{0,Q} \cap \Sigma_{0,Q}' = \emptyset\) if \(Q \neq Q'\) by Proposition 9(ii).

For each \(Q \in \mathcal{P}(0)\) we may perturb the points in \(\Sigma_{0,Q}\) by distance at most \(r_0\) such that \(\partial \Sigma_{0,Q} \subseteq \partial R_0(t_0)B_0,\) the latter set being quasi-isometric (with constants independent of \(Q\)) to \(\partial R_0\) by Proposition 9(vi).

By Proposition 17, there is some \(r_1 > 0\) (that depends on the constants of the above quasi-isometry) and a coarse manifold \(\Sigma_{0,Q}' \subseteq \partial R_0(t_0)B_0\) of scale \(r_1\) for each \(Q \in \mathcal{P}(0)\) such that the coarse manifold

\[
\Sigma_1 = \Sigma_{0,\partial} \cup \bigcup_{Q \in \mathcal{P}(0)} \Sigma_{0,Q}'
\]

is of scale \(r_1,\) of the same topological type as \(\Sigma_0,\) and its volume is \(O(\text{vol}(\Sigma)^k)\) for some \(k.\)

Also note that by Proposition 9(iv),

\[
\Sigma_1 \subseteq \left( \bigcup_{Q \in \mathcal{P}(0)} R_0B_0 \right) - \left( \bigcup_{Q \in \mathcal{P}(0)} R_0(2t_0)B_0 \right) \subseteq \bigcup_{Q \in \mathcal{P}(0)} R_0B_1.
\]

Furthermore, since \(\mathcal{G}(\mathcal{O}_S) \cap R_0(t_0)B_0 = \emptyset\) by Proposition 9(iii), we have \(\partial \Sigma_0 = \partial \Sigma_1.\)
Repeat this argument with \( 1 \leq n < |\Delta| - 1 \) in place of 0 above. The result is a coarse manifold \( \Sigma_{\partial|\Delta|} \) of scale \( r_{\partial|\Delta|} \) (for some \( r_{\partial|\Delta|} > 0 \)); of the same topological type as \( \Sigma_0 \); with \( \partial \Sigma_{\partial|\Delta|} = \partial \Sigma_0 \); of volume \( O(\text{vol}(\Sigma)^k) \) for some \( k \); and contained in

\[
\left( \bigcup_{Q \in \mathcal{P}(|\Delta| - 1)} R_Q B_{|\Delta| - 1} \right) - \left( \bigcup_{Q \in \mathcal{P}(|\Delta| - 1)} R_Q (2|\Delta| - 1) B_{|\Delta| - 1} \right)
\]

and hence in \( G(O_S) B_{|\Delta|} \) by Proposition 9(\( v \)).

As \( G(O_S) B_{|\Delta|} \) is a finite Hausdorff distance from \( G(O_S) \), our proof is complete.

7. Isoperimetric inequalities

In this section, we prove that our main result implies Corollary 5. That is, we show that \( G(O_S) \) satisfies a polynomial \( m \)-dimensional isoperimetric inequality when \( m \leq |S| - 2 \).

Let \( X \) be an \((|S| - 2)\)-connected CW-complex that \( G(O_S) \) acts on, cellurally, freely, properly, and cocompactly. Choose a basepoint \( x \in X \) and let \( \phi : G(O_S) \to G(O_S) \cdot x \) be the orbit map. It is a bijective quasi-isometry where \( G(O_S) \) is endowed with the restriction of the left-invariant metric on \( G(O_S) \), and \( G(O_S) \cdot x \) is endowed with the restriction of the path metric on \( X \).

Let \( \Sigma \subseteq X \) be a cellular \( m \)-sphere for \( m \leq |S| - 2 \). Every point in \( \Sigma \) is a uniformly bounded distance from a point in the orbit \( G(O_S) \cdot x \). Thus, there exists some \( r_0 > 0 \) such that after perturbing \( \Sigma \) by a uniformly bounded amount, the Hausdorff distance between \( \Sigma \) and \( \Sigma \cap G(O_S) \cdot x \) is uniformly bounded and \( \Sigma \cap G(O_S) \cdot x \) is an \( r_0 \)-coarse \( m \)-sphere.

Therefore, \( \phi^{-1}(\Sigma \cap G(O_S) \cdot x) \) is an \( r_1 \)-coarse \( m \)-sphere in \( G(O_S) \) for some \( r_1 > 0 \) that depends only on \( r_0 \) and the quasi-isometry constants of \( \phi \).

Since \( G \) is quasi-isometric to a \( \text{CAT}(0) \) space, there is an \( r_2 \)-coarse \((m + 1)\)-disk \( D \subseteq G \) with \( \partial D = \phi^{-1}(\Sigma \cap G(O_S) \cdot x) \) and \( \text{vol}(D) = O(\text{vol}(\Sigma)^{(m+1)/m}) \).

By Theorem 4, there is some \( r_2 > 0 \) and a polynomial \( f \) such that there exists an \( r_2 \)-coarse \((m + 1)\)-disk \( D' \subseteq G(O_S) \) with \( \partial D' = \phi^{-1}(\Sigma \cap G(O_S) \cdot x) \) and \( \text{vol}(D') = f(\text{vol}(\Sigma)^{(m+1)/m}) \).

There is some \( r_3 > 0 \) depending only on \( r_2 \) and on the quasi-isometry constants of \( \phi \) such that \( \phi(D') \subseteq X \) is an \( r_3 \)-coarse \((m + 1)\)-disk with boundary \( \Sigma \cap G(O_S) \cdot x \) and \( \text{vol}(\phi(D')) = \text{vol}(D') \).

Starting with the 0-skeleton given by \( \phi(D') \), we connect adjacent vertices in the coarse manifold \( \phi(D') \) with 1-cells. If the two adjacent points are contained in \( \Sigma \cap G(O_S) \cdot x \), then we use the 1-cell that connects them in \( \Sigma \). We continue by the dimension of the skeleton to define a topological \((m + 1)\)-ball \( D'' \subseteq X \) that is a uniformly bounded Hausdorff distance from \( \phi(D') \), whose boundary is \( \Sigma \), and that contains \( O(\text{vol}(D')) \) many cells. This proves Corollary 5.

Notice that if \( f \) were a linear polynomial, the proof above establishes a Euclidean isoperimetric inequality, and thus that Conjecture 2 implies Conjecture 3.
8. Appendix: Reduction theory and a proof of Proposition 9

In this section we provide a proof of Proposition 9.

Throughout this section, \( F \) will be the set given in Theorem 8. We will also make use of the notation introduced in Section 1.

We begin with the main result from reduction theory:

**Theorem 18.** There is a bounded set \( B \subseteq G \) such that

\[
G(\mathcal{O}_S)F U M A_1^G B = G.
\]

*Proof.* Springer [17, 2.1F] provides an adelic version of this theorem. See Godement [10, Theorem 11] for the proof that the adelic version implies this theorem using Theorem 8. ([10, Theorem 11] is stated for number fields, but the proof works for an arbitrary global field.) \( \square \)

8.1. Root choice

We will need to make use of a carefully chosen positive root. We explain that choice below along with some related notation.

Given \( w \in W \) and \( \alpha \in \Phi \), we let \( a^w_\alpha \in \Phi \) be defined by \( a^w_\alpha(a) = \alpha(w^{-1} a)w \). Then we define \( \Delta^w = \{a^w_\alpha \mid \alpha \in \Delta \} \), and we let \((\Phi^w)^+\) and \((\Phi^w)^-\) be the sets of positive and negative roots respectively with respect to the simple roots \( \Delta^w \).

The sets of roots \( \Phi^+, (\Phi^w)^+, \) and \( (\Phi^w)^- \) are closed under addition, so \( \Phi^+ \cap (\Phi^w)^+ \) and \( \Phi^+ \cap (\Phi^w)^- \) are as well. Hence, there are corresponding unipotent subgroups \( U_{\Phi^+ \cap (\Phi^w)^+}, U_{\Phi^+ \cap (\Phi^w)^-} \subseteq U_{\Phi^+} \) that we label as \( U_{w,+} \) and \( U_{w,-} \) respectively. They are each normalized by \( MA \leq Z_G(A) \) (see e.g. [3, 21.9(ii)]).

In the case \( w \neq 1 \), we have \( \Phi^+ \cap (\Phi^w)^- \neq \emptyset \), and the next lemma determines a choice of a root \( \tau_{j,I,w} \in \Phi^+ \cap (\Phi^w)^- \) that has some properties we will need later in this section. As an example of the following lemma, if \( w \) represents the longest element of the Weyl group then \( \Phi^+ \cap (\Phi^w)^- = \Phi^+ \) and \( \tau_{j,I,w} \) is the highest root with respect to \( \Phi^+ \).

**Lemma 19.** Suppose \( I, J \subseteq \Delta \), that \( w \in W \), and \( w \notin P_J(K) \). Then there is some \( \tau_{j,I,w} \in \Phi^+ \cap (\Phi^w)^- \) such that

(i) if \( \alpha \in \Phi^+ \cap (\Phi^w)^- \) then \( \alpha + \tau_{j,I,w} \notin \Phi^+ \);

(ii) if \( \alpha \in A_1^J(1) \) then \( |\tau_{j,I,w}(a)| \geq 1 \); and

(iii) for any \( r > 0 \) there is some \( t > 1 \) such that \( a \in wA_1^J(t) \) implies \( |\tau_{j,I,w}(a)| < r \).

*Proof.* Let \( \Sigma \) be the apartment of the spherical building for \( G(K) \) that corresponds to \( A \). Let \( C_\Phi, C_\Phi^-, C_\Phi^- \subseteq \Sigma \) be the simplices corresponding to \( P, P^-, \) and \( P^- \) respectively.

We write \( \Delta \) as \( (\alpha_1, \ldots, \alpha_n) \), and for each \( j \), let \( H_j \subseteq \Sigma \) be the simplicial hemisphere corresponding to \( \alpha_j \).

Either \( C_\Phi^- \not\subseteq H_j \) for some \( j \), or else \( C_\Phi^- \subseteq \bigcap_{j=1}^n H_j = C_\Phi \), which implies through the type preserving action of the Weyl group on \( \Sigma \) that \( P_J = P_J \) and thus \( w \in P_J(K) \).

By the hypotheses of the lemma, we proceed under the assumption that there is some \( j \) such that \( C_\Phi^- \not\subseteq H_j \). Then clearly \( C_\Phi \not\subseteq H_j \), so that \( \alpha_j \in \Phi^+ \cap (\Phi^w)^- \).
Let $\Delta^w = \{\beta_1, \ldots, \beta_n\}$ and choose the ordering on the roots such that $J^w = \{\beta_1, \ldots, \beta_{|J|}\}$. Because $\alpha_j \in (\Phi^w)^-$, we have $\alpha_j = \sum_i m_{0,i} \beta_i$ where $m_{0,i} \leq 0$ for all $i$.

Choose a root $\tau_1 \in \Phi^+ \cap (\Phi^w)^-$ such that $\tau_1 = \sum_i m_{1,i} \beta_i$ where $m_{1,i} \leq m_{0,i}$ for all $i$ and the coefficient $m_{1,1}$ is minimal possible.

Then choose a root $\tau_2 \in \Phi^+ \cap (\Phi^w)^-$ such that $\tau_2 = \sum_i m_{2,i} \beta_i$ where $m_{2,i} \leq m_{1,i} \leq m_{0,i}$ for all $i$ and $m_{2,2}$ is minimal. (Notice of course that $m_{2,1} = m_{1,1}$ for any choice of $\tau_2$ by our choice of $\tau_1$.)

Continue in this manner until obtaining a root $\tau_n \in \Phi^+ \cap (\Phi^w)^-$ such that $\tau_n = \sum_i m_{n,i} \beta_i$ where $m_{n,i} \leq m_{n-1,i} \leq \cdots \leq m_{0,i} \leq 0$ for all $i$ and such that if there is a root $\sum_i m_i \beta_i = \Phi^+ \cap (\Phi^w)^-$ with $m_i \leq m_{n,i}$ for all $i$, then $\sum_i m_i \beta_i = \tau_n$.

We rename $\tau_n$ as $\tau_{J_l, w}$. If $\alpha \in \Phi^+ \cap (\Phi^w)^-$, then $\alpha + \tau_{J_l, w} \notin \Phi^+ \cap (\Phi^w)^-$ by the previous paragraph. But $\Phi^+ \cap (\Phi^w)^-$ is closed under addition, so it must be that $\alpha + \tau_{J_l, w} \notin \Phi$. This is part (i) of the lemma.

Part (ii) follows from $\tau_{J, l, w} \in \Phi^+$.

For part (iii), notice that $\mathcal{C}_{\nu, p} \not\subset \mathcal{H}_J$ implies that $\alpha_j \notin [J^w]$. Therefore $\tau_{J, l, w} \not\in [J^w]$, and in particular, $m_{n,k} < 0$ for some $k > |J|$.

Let $a \in \mathcal{A}^+_x(t)$ where $t > 1$. Then $|\beta_i(a)| = 1$ if $i \leq |J|$ and $|\beta_i(a)| \geq t$ for all $i > |J|$. Therefore $|\beta_i(a)|^{m_{n,i}} \leq 1$ for all $i$ (since $m_{n,i} \leq 0$), and

$$|\tau_{J_l, w}(a)| = \prod_{v \in S} |\tau_{J_l, w}(a_v)| = \prod_{v \in S} \left( \sum_i m_{n,i} \beta_i(a_v) \right)_{|v|} = \prod_{v \in S} \prod_{i} (|\beta_i(a_v)|_{|v|})^{m_{n,i}} \leq \prod_{i} |\beta_i(a)|^{m_{n,i}} \leq t^{m_{n,k}}.$$ \hfill $\square$

8.2. Proximity to integer points

Our proof will rely on identifying certain points in $G$ that are close to points in $G(O_S)$ (Lemma 21 below), identifying certain points in $G$ that are far from points in $G(O_S)$ (Lemma 23 below), and then contrasting these two identifications.

Lemma 20. Suppose $X \subseteq G(K)$ is a finite set. Then there is a finite set $B \subseteq G$ such that $X G(O_S) \subseteq G(O_S) B$.

Proof. For $x \in X$, we let $\Gamma_x = G(O_S) \cap x G(O_S)x^{-1}$. Since $x \in G(K)$, there is a finite set $\{y_1, \ldots, y_k\}$ of right coset representatives for $\Gamma_x$ in $x G(O_S)x^{-1}$.

Thus, $x G(O_S) = x G(O_S)x^{-1} x = \bigcup \Gamma_x y_i x \subseteq G(O_S) \{y_1, \ldots, y_k\} x$. \hfill $\square$

As a consequence of the previous lemma we have

Lemma 21. There is some $C > 0$ such that any point in

$$G(O_S)^{-1} G(O_S) F G(O_S) U M W^{-1}$$

is within distance $C$ of a point in $G(O_S)$. 

Proof. Since $U$ is unipotent and $M$ is $K$-anisotropic, it follows that there is some compact set $B \subseteq UM$ such that $(UM)(O_S)B = UM$. Thus, $G(O_S)F^{-1}G(O_S)FG(O_S)UMW^{-1}$ is contained in $G(O_S)F^{-1}G(O_S)FG(O_S)BW^{-1}$ and the lemma follows from the previous lemma.

For $\tau \in \Phi$ let $A_{\tau}$ be the kernel of $\tau$ in $A$. Let

$$A(\tau, t) = \{a \in A \mid |\tau(a)| \geq t\}$$

and fix $a_{\tau} \in A$ such that $|\tau(a_{\tau})| > 1$.

**Lemma 22.** There is some $C > 0$ such that for any $k_0 \in \mathbb{N}$, there is some $t_0 > 1$ such that the Hausdorff distance between $\bigcup_{k \geq k_0} A(O_S)A_{\tau}(a_{\tau})^k$ and $A(\tau, t_0)$ is at most $C$.

**Proof.** Since $O_S \subseteq K_w$ is bounded if $w \notin S$, we see that $A(O_S) \leq A(K_w)$ is bounded. Hence the image of $A(O_S)$ under the map $g \mapsto |\tau(g)|_w$ is bounded and therefore is trivial.

For any $x \in K$, the product of $|x|_v$ over all valuations $v$ of $K$ equals 1, so it follows that $|\tau(a)| = 1$ for any $a \in A(O_S)$.

Notice also that $|\tau(a)| = 1$ for any $a \in A_{\tau}$, so $A(O_S)A_{\tau} \leq A(\tau, 1) \cap A(-\tau, 1)$ and the lemma will follow for $t_0 = |\tau(a_{\tau})^{k_0}|$ if we establish that $A(O_S)A_{\tau}$ is a finite Hausdorff distance from $A(\tau, 1) \cap A(-\tau, 1)$. This essentially follows from a dimension count. (By dimension, we mean the dimension of a quasi-isometric Euclidean space.)

The group $A_{\tau}$ is quasi-isometric to Euclidean space of dimension $|S|(\text{rank}_K(A) - 1)$. Dirichlet’s units theorem shows that the dimension of $A(O_S)$ equals $(|S| - 1)(\text{rank}_K(A)$ and that the dimension of $A_{\tau}(O_S)$ equals $(|S| - 1)(\text{rank}_K(A) - 1)$.

Since $A(O_S) \cap A_{\tau} = A_{\tau}(O_S)$, it follows that the dimension of $A(O_S)A_{\tau}$ equals

$$(|S| - 1)(\text{rank}_K(A) + |S|)(\text{rank}_K(A) - 1) - (|S| - 1)(\text{rank}_K(A) - 1).$$

The above number is $|S|\text{rank}_K(A) - 1$, which is the dimension of $A(\tau, 1) \cap A(-\tau, 1)$. Therefore, $A(O_S)A_{\tau}$ is a finite Hausdorff distance from $A(\tau, 1) \cap A(-\tau, 1)$, which proves the lemma.

We will use the previous lemma to establish the following

**Lemma 23.** Suppose $I, J \subseteq \Delta$, $w \in W$, and $w \notin P_f(K)$. Then for any $C > 0$, there exists some $t > 1$ such that any $g \in U_{w, \ldots MA(\tau_{I,J,w}, t)}$ is at distance at least $C$ from $G(O_S)$.

**Proof.** Choose $\gamma \in U_{(\tau_{I,J,w})(O_S)}$ with $\gamma \neq 1$.

For $k \in \mathbb{N}$, let

$$O_k = \{u \in U_{(\tau_{I,J,w})} \mid d(u, 1) \leq 1/k\} \quad \text{and} \quad F_k = \{g \in G \mid g^{-1}\gamma g \in O_k\}$$

so that $F_{k+1} \subseteq F_k$.

For $k$ sufficiently large, $O_k \cap G(O_S) = 1$, which implies $F_k \cap G(O_S) = \emptyset$, and in fact $\lim_{k \to \infty} d(F_k, G(O_S)) = \infty$. Let $m$ be such that the distance between $F_m$ and $G(O_S)$ is sufficiently large.
Note that \( \lim_k (a_{\tau J,w})^{-k} g(a_{\tau J,w})^k = 1 \), so there is some \( k_0 \in \mathbb{N} \) such that \( (a_{\tau J,w})^k \in F_m \) if \( k \geq k_0 \).

Let \( \alpha \in \Phi^+ \cap (\Phi^*)^- \). By Lemma 19(i), commutators of elements in \( U(\alpha) \) with elements in \( U(\tau J,w) \) are contained in \( U(\alpha + \tau J,w) = 1 \). That is, the group \( U_{\tau J,w} \) commutes with \( U(\tau J,w) \), and in particular, with \( \gamma \).

Notice that \( A_{\tau J,w} \) also commutes with \( \gamma \in U(\tau J,w) \). Therefore, if \( g \in U_{\tau J,w} - A_{\tau J,w} \) and \( k \geq k_0 \), then

\[
(a_{\tau J,w})^{-k} g^{-1} \gamma g(a_{\tau J,w})^k = (a_{\tau J,w})^{-k} \gamma (a_{\tau J,w})^k \in O_m
\]

so \( g(a_{\tau J,w})^k \in F_m \).

The distance between \( G(O_S) \) and \( \lambda F_n \) for any \( \lambda \in G(O_S) \) equals the distance between \( F_n \) and \( \lambda^{-1} G(O_S) = G(O_S) \). Therefore, the union over \( k \geq k_0 \) of the sets

\[
U_{\tau J,w} M(O_S) A(O_S) A_{\tau J,w} (a_{\tau J,w})^k = M(O_S) A(O_S) U_{\tau J,w} - A_{\tau J,w} (a_{\tau J,w})^k
\]

is a sufficiently large distance from \( G(O_S) \).

Using Lemma 22, we find that for some \( t > 1 \) there is a sufficiently large distance between \( G(O_S) \) and \( U_{\tau J,w} M(O_S) A(\tau J,w, t) \), and thus a sufficiently large distance between \( G(O_S) \) and \( U_{\tau J,w} M(O_S) A(\tau J,w, t) \) where \( B \) is a given compact set. Precisely, since \( M \) is \( K \)-anisotropic, we choose \( B \subseteq M \) to be a compact fundamental domain for \( M(O_S) \). Our lemma follows since elements of \( B \) commute with those in \( A \). \( \square \)

Notice that in the above proof, the properties of \( \tau J,w \) are used to find an integral unipotent element \( \gamma \) that commutes with the unipotent group \( U_{\tau J,w} \). Thus, if \( U_{\tau J,w} \) were replaced with the trivial group in the above lemma, we would be free to apply the resulting statement to any root \( \tau \in \Phi \). That is, the proof of the preceding lemma simplifies to prove the following

**Lemma 24.** Suppose \( \tau \in \Phi \). Then for any \( C > 0 \), there exists some \( t > 1 \) such that any \( g \in A(\tau, t) \) is at distance at least \( C \) from \( G(O_S) \).

As an immediate consequence of Lemma 23 we have the following

**Lemma 25.** Suppose \( I, J \subseteq \Delta \), that \( w \in W \), and \( w \notin P_j(K) \). For any bounded set \( B \subseteq G \), there is some \( s > 1 \) such that the sets \( U M A(\tau J,w, -s) B \) and \( U M A(-\tau J,w, s) B \) are disjoint.

**Proof.** Recall that \( MA \) normalizes \( U \) and \( wU \), elements of \( A \) commute with elements in \( M \), and the inverse of an element in \( A(-\tau J,w, s) \) is contained in \( A(\tau J,w, s) \).

Thus, we can multiply given elements from each of the sets in question on the left by inverses of elements in \( U M A(-\tau J,w, s) \), and on the right by inverses of elements in \( B \), to see that the lemma follows from showing that the sets \( U M A(-\tau J,w, s) \) and \( B B^{-1} \) are disjoint for some \( s > 1 \).

Recall that \( U_{w,} U_{w,-} \leq U \), \( U_{w,+} U_{w,-} = U \), and \( U_{w,+} \leq \). Thus, \( U U = U U_{w,} U_{w,-} = U U_{w,-} \), and after multiplying on the left by the inverses of elements
in \(^wu\), we are left to prove that the sets \(U_{w, -} MA(t_{J, I, w, s})\) and \(wUBB^{-1}\) are disjoint for some \(s > 1\).

But \(wU\) is a unipotent \(K\)-group, so there is some compact set \(B_w \subseteq wU\) such that \(wU = (wU)(O_3)B_w\). Thus, we need to show that the sets \(U_{w, -} MA(t_{J, I, w, s})\) and \((wU)(O_3)B_wBB^{-1}\) are disjoint for some \(s > 1\). This follows from Lemma 23. □

8.3. Disjointness of distinct parabolic regions

The goal of this subsection is to prove Lemma 32, which will quickly imply that distinct parabolic regions are—after removing a neighborhood of their boundaries—disjoint.

Given \(\gamma_1, \gamma_2, \gamma_3 \in G(O_3)\) and \(f_1, f_2 \in F\), let \(p_2wp_1 \in P(K)WP(K)\) be such that \(\gamma_3^{-1}f_2^{-1}\gamma_2 f_1 \gamma_1 = p_2wp_1\). Let \(p_i = u_im_i a_i\) for \(u_i \in U(K), m_i \in M(K)\), and \(a_i \in A(K)\).

Given \(\gamma_3^{-1}f_2^{-1}\gamma_2 f_1 \gamma_1\), our choice of group elements \(p_2, w, p_1, u_2, m_2, a_2, u_1, m_1, a_1\) will be fixed for Lemmas 26 and 27.

**Lemma 26.** Suppose \(I, J \subseteq \Delta, w \in W, \) and \(w \notin P_J(K)\). Suppose \(s > 0\) is given. Then there is some \(t > 1\) (independent of \(\gamma_3^{-1}f_2^{-1}\gamma_2 f_1 \gamma_1\)) such that

\[
a_2 wa_1 A_{J, I, w}^{-1} t^{-1} w^{-1} \subseteq \Lambda(-t_{J, I, w, s}).
\]

**Proof.** Let \(u_2 = u_2^{-1}(a_2^+)\) where \(u_2^- \in U_{w, -}\) and \(u_2^+ \in U_{w, +}\). Since \(MA\) normalizes \(U_{w, +}\) we have

\[
a_2^{-1}m_2^{-1} u_2^+ \in U_{w, +} \subseteq U_{(\Phi w)^+}.
\]

Notice that if \(\alpha \in \Phi\) and \(v \in U_{(\alpha w^{-1})}\), then \(w^{-1}v \in U_{(\alpha w^{-1})}\). Therefore

\[
(m_2 a_2 w)^{-1} u_2^+ = w^{-1}(a_2^{-1}m_2^{-1} u_2^+) \in U_{\Phi^+} = U.
\]

It follows that

\[
(u_1m_1)^{-1} [(m_2 a_2 w)^{-1} u_2^+] \in UM
\]

and thus

\[
a_1^{-1} [(u_1m_1)^{-1} [(m_2 a_2 w)^{-1} u_2^+]] \in UM
\]

since \(A\) normalizes \(UM\).

By Lemma 21, the following point is a bounded distance from \(G(O_3)\):

\[
\gamma_3^{-1}f_2^{-1}\gamma_2 f_1 \gamma_1 a_1^{-1} [(u_1m_1)^{-1} [(m_2 a_2 w)^{-1} u_2^+] w^{-1} = p_2wp_1 a_1^{-1} [(u_1m_1)^{-1} [(m_2 a_2 w)^{-1} u_2^+] w^{-1} = u_2 m_2 a_2 w (u_1m_1)^{-1} [(u_1m_1)^{-1} [(m_2 a_2 w)^{-1} u_2^+] w^{-1} = u_2 m_2 a_2 w (u_1m_1)^{-1} [(m_2 a_2 w)^{-1} u_2^+] a_1 w^{-1} = u_2 m_2 a_2 w (m_2 a_2 w)^{-1} u_2^+ a_1 w^{-1} = u_2 u_2 m_2 a_2 w a_1 w^{-1} = (u_2 m_2) a_2 w a_1 w^{-1}.
\]
By Lemma 23, there is some \( r > 1 \) that is independent of \( a_2(wa_1w^{-1}) \in A \) and such that \( |\tau_{J,I,w}(a_2wa_1w^{-1})| < r \).

By Lemma 19(iii) there is some \( t > 1 \) such that \( |\tau_{J,I,w}(a)| < 1/sr \) for any \( a \in wA_\gamma^+(t) \).

Therefore,

\[
|\tau_{J,I,w}(a_2wa_1w^{-1})a| = |\tau_{J,I,w}(a_2wa_1w^{-1})||\tau_{J,I,w}(a)| < 1/s
\]

and thus \( |\tau_{J,I,w}(a_2wa_1w^{-1})a| > s \).

\[
\text{Lemma 27. Suppose } I, J \subseteq \Delta. \text{ For any bounded set } B \subseteq G \text{ there is some } t > 1 \text{ (independent of } \gamma_3 \text{)} \text{ such that if } \gamma_3^{-1}f_2^{-1}\gamma_2f_1\gamma_1 \in G(\mathcal{O}_S)F^{-1}G(\mathcal{O}_S)FG(\mathcal{O}_S) \text{ is not contained in } \mathcal{P}_J(K) \text{, then the sets } \gamma_3^{-1}f_2^{-1}\gamma_2f_1\gamma_1UMA_\gamma^+(t)B \text{ and } UMA_\gamma^+(t)B \text{ are disjoint.}
\]

\[
\text{Proof. If } \gamma_3^{-1}f_2^{-1}\gamma_2f_1\gamma_1 \text{ is not contained in } \mathcal{P}_J(K) \text{ then } w \notin \mathcal{P}_J(K).
\]

The group \( A \) commutes with \( M \) and it normalizes \( U \) and \( wU \). The group \( M \) normalizes \( U \) and \( wU = M \). Thus,

\[
\gamma_3^{-1}f_2^{-1}\gamma_2f_1\gamma_1UMA_\gamma^+(t)B = p_2wpa_1UMA_\gamma^+(t)B = p_2wUMa_1A_\gamma^+(t)B
\]

By Lemma 25, there is some \( s > 1 \) such that \( UMA(\tau_{J,I,w}, 1)[B \cup wB] \) is disjoint from \( wUMA(\tau_{J,I,w}, s)B \cup wB \).

By Lemma 19, \( A_\gamma^+(1) \subseteq A(\tau_{J,I,w}, 1) \). By Lemma 26, there is some \( t > 1 \) such that \( a_2wa_1A_\gamma^+(t)w^{-1} \subseteq A(\tau_{J,I,w}, s) \). Therefore, \( u_\gamma^{-1}UMA_\gamma^+(1)B \) is disjoint from \( wUMa_2wa_1A_\gamma^+(t)B \), which proves the lemma.

\[
\text{Lemma 28. Suppose } I, J \subseteq \Delta \text{ with } |I| = |J| \text{ and } I \neq J. \text{ For any bounded set } B \subseteq G \text{ there is some } t > 1 \text{ (independent of } \gamma_3 \text{)} \text{ such that if } \gamma_3^{-1}f_2^{-1}\gamma_2f_1\gamma_1 \in G(\mathcal{O}_S)F^{-1}G(\mathcal{O}_S)FG(\mathcal{O}_S) \text{ is contained in } \mathcal{P}_J(K) \text{ and } \mathcal{P}_I(K), \text{ then the sets } \gamma_3^{-1}f_2^{-1}\gamma_2f_1\gamma_1A_\gamma^+(t)B \text{ and } A_\gamma^+(t)B \text{ are disjoint.}
\]

\[
\text{Proof. We let } p = \gamma_3^{-1}f_2^{-1}\gamma_2f_1\gamma_1 \text{. Notice that } p \in \mathcal{P}_{I\cap J}(K) \text{ so that } p = uma \text{ where } a \in A_{I\cap J}.
\]

Elements of \( A_I \leq A_{I\cap J} \) commute with \( ma \), and they normalize \( U_{\Phi(I\cap J)^+} \). Therefore, \( A_\gamma^+(t)^{-1}p \subseteq U_{\Phi(I\cap J)^+}pA_\gamma^+(t)^{-1} \). Hence,

\[
A_\gamma^+(t)^{-1}pA_\gamma^+(t)B \subseteq U_{\Phi(I\cap J)^+}pA_\gamma^+(t)^{-1}A_\gamma^+(t)B
\]

and the lemma will follow if we show that \( p^{-1}U_{\Phi(I\cap J)^+}BB^{-1} \) is disjoint from \( A_\gamma^+(t)^{-1}A_\gamma^+(t) \).

Since \( U_{\Phi(I\cap J)^+} \) is a unipotent \( K \)-group, there is some compact set \( B_{I\cap J} \subseteq U_{\Phi(I\cap J)^+} \) such that \( U_{\Phi(I\cap J)^+}(\mathcal{O}_S)B_{I\cap J} = U_{\Phi(I\cap J)^+} \). Therefore, \( p^{-1}U_{\Phi(I\cap J)^+}BB^{-1} \) is contained in

\[
G(\mathcal{O}_S)FG(\mathcal{O}_S)F^{-1}G(\mathcal{O}_S)U_{\Phi(I\cap J)^+}(\mathcal{O}_S)B_{I\cap J}BB^{-1}
\]

and thus is contained in a metric neighborhood of \( G(\mathcal{O}_S) \) by Lemma 21.
The set \([I] \cap \Phi(J)^+\) is nonempty since \(J\) does not contain \(I\), and we choose \(\tau \in [I] \cap \Phi(J)^+\). Thus \(A_1^{-1}(t)A_1^{-1}(t) \subseteq A(t, t)\) and the lemma follows from Lemma 24.

**Lemma 29.** Suppose \(I, J \subseteq \Delta\) with \([I] = [J]\). Let \(B \subseteq G\) be a bounded set. There is a \(t > 1\) such that if \(f_2^{-1} \gamma_2 f_1 \in F^{-1}G(O_S)F\) and either \(f_2^{-1} \gamma_2 f_1 \notin P_I(K)\), \(f_2^{-1} \gamma_2 f_1 \notin P_I(K)\), or \(J \neq I\), then the sets \(f_2^{-1} \gamma_2 f_1 P_I(O_S)A_1^{-1}(t)B\) and \(P_I(O_S)A_1^{-1}(t)B\) are disjoint.

**Proof.** By the previous two lemmas there is some \(\tau > 1\) such that for any \(\gamma_3 \in P_I(O_S)\) and \(\gamma_1 \in P_I(O_S)\), we have that \(f_3^{-1} \gamma_2 f_1 \gamma_1 A_1^{-1}(t)B\) is disjoint from \(A_1^{-1}(t)B\) as long as either \(\gamma_3^{-1} f_2^{-1} \gamma_2 f_1 \gamma_1 \notin P_I(K)\), \(\gamma_1^{-1} f_2^{-1} \gamma_2 f_3 \gamma_3 \notin P_I(K)\), or \(I \neq J\).

If \(I = J\) and \(\gamma_1 f_2^{-1} \gamma_2 f_1 \gamma_1 \in P_I(K)\), then \(f_2^{-1} \gamma_2 f_1 \gamma_1 \in P_I(K)\), \(\gamma_1^{-1} f_2^{-1} \gamma_2 f_3 \gamma_3 \notin P_I(K)\), or \(I \neq J\).

If \(I = J\) and \(\gamma_1 f_2^{-1} \gamma_2 f_3 \gamma_3 \notin P_I(K)\), then \(f_2^{-1} \gamma_2 f_2 \in \gamma_1 P_I(K)\) disjoint from \(A_1^{-1}(t)B\), and hence \(f_2^{-1} \gamma_2 f_1 \in P_I(K)\).

At this point, we have done most of the work that was required in this subsection. The next three lemmas provide some cosmetic reformulation of what we have done.

We let \(A_1^{-1}(t) = \{a \in A_I \mid |\alpha(a)|_w \geq t \text{ if } a \in \Delta - I\text{ and } v \in S\}\).

**Lemma 30.** For \(I \subseteq \Delta\) there is some bounded set \(B_{A_I} \subseteq A_I\) containing 1 such that for any \(t > 1\), \(A_1^{-1}(t) \subseteq A_I(O_S)A_1^{-1}(\sqrt{t})B_{A_I}\).

**Proof.** If \(|S| = 1\), then \(A_1^{-1}(t) = A_1^{-1}(t)\) and the lemma follows.

If \(|S| > 1\), then let \(a \in A_1^{-1}(t)\) and choose \(w \in S\) such that \(|\alpha(a)|_w \geq |\alpha(a)|_v\) for \(v \in S - \{w\}\).

By Lemma 12, there is some \(a_0 \in A_I(O_S)\) such that \(|\alpha(a_0a)|_w \geq \sqrt{t}\) for all \(v \in S - \{w\}\) and the distance between \(|\alpha(a_0a)|_w\) and \(\sqrt{t}\) is uniformly bounded. Thus, there is some bounded \(a_0 \in A_I\) such that \(a_0 a_0 a_0 \in A_1^{-1}(\sqrt{t})\). Hence, \(a \in a_0^{-1} A_1^{-1}(\sqrt{t}) B_{A_I}\). □

For \(c > 0\) we let \(B_I(c) = \{u \in U_{\Phi(I)^+} \mid \|u\| \leq c\}\). Note that \(B_I(c)\) is compact, and since \(U_{\Phi(I)^+}\) is unipotent, there is some \(c_0\) such that \(U_{\Phi(I)^+} B_I(c_0) = U_{\Phi(I)^+}\).

We let \(B_I = B_I(c_0)\). Notice that if \(a \in A_1^{-1}(1)\) and \(b \in B_I\) then \(a^{-1}ba \in B_I\) so that \(B_I A_1^{-1}(t) \subseteq A_1^{-1}(t)B_I\) when \(t > 1\).

**Lemma 31.** Given \(I \subseteq \Delta\) there is some bounded set \(B \subseteq G\) such that if \(t > 1\) then

\[U_{\Phi(I)^+} A_I(O_S) A_1^{-1}(t) \subseteq P_I(O_S) A_1^{-1}(\sqrt{t}) B_I.\]

**Proof.** Because \(U_{\Phi(I)^+}\) is normalized by \(M_I(O_S) \leq M_I\) and \(A_I(O_S) \leq A_I\), Lemma 30 yields the following inclusions of sets:

\[U_{\Phi(I)^+} M_I(O_S) A_1^{-1}(t) \subseteq U_{\Phi(I)^+} M_I(O_S) A_I(O_S) A_1^{-1}(\sqrt{t}) B_{A_I}\]
\[= M_I(O_S) A_I(O_S) U_{\Phi(I)^+} A_1^{-1}(\sqrt{t}) B_{A_I}\]
\[= M_I(O_S) A_I(O_S) U_{\Phi(I)^+} (O_S) B_I A_1^{-1}(\sqrt{t}) B_{A_I}\]
\[\subseteq P_I(O_S) A_1^{-1}(\sqrt{t}) B_I B_{A_I}.\] □

And now we have the lemma that this subsection was devoted to:
Lemma 32. Let $I, J \subseteq \Delta$ with $|I| = |J|$. Let $B \subseteq G$ be a bounded set. There is a $t > 1$ such that if $f_2^{-1} \gamma_2 f_1 \in F^{-1}G(O_S)F$ and either $f_2^{-1} \gamma_2 f_1 \notin P_J(K)$, $f_2^{-1} \gamma_2 f_1 \notin P_I(K)$, or $J \neq I$, then the sets $f_2^{-1} \gamma_2 f_1 U_{\Phi(J)} A_J^+(t) B$ and $U_{\Phi(I)} A_I^+(t) B$ are disjoint.

Proof. As $A_J^+(\sqrt{t})$ is contained in $A_J^+(t)$, the proof is a straightforward combination of Lemmas 29 and 31. \hfill \square

8.4. Coarse stabilization of parabolic regions under parabolic translations

In the next lemma we will prove that translating the parabolic region associated to $P_J$ by elements of $P_J(K) \cap F^{-1}G(O_S)F$ stabilizes the parabolic region up to a bounded Hausdorff distance.

Lemma 33. Let $J \subseteq \Delta$. There is a bounded set $B \subseteq G$ such that if $t > 1$ and $f_2^{-1} \gamma f_1 \in F^{-1}G(O_S)F$ with $f_2^{-1} \gamma f_1 \in P_J(K)$, then the set $f_2^{-1} \gamma f_1 U_{\Phi(J)} A_J^+(t) B$ is contained in $U_{\Phi(J)} A_J^+(t) B$.

Proof. Notice that $f_2^{-1} \gamma f_1 P_J = P_J$ and hence $\gamma f_1 P_J = f_2 P_J$.

Let $\gamma_0$ be a fixed element of $G(O_S)$ with $f_2^{-1} \gamma_0 f_1 \in P_J(K)$. Then $\gamma_0 f_1 P_J = f_2 P_J$, and by letting $\lambda = \gamma_0^{-1}$ we have

$$\lambda f_2 P_J = \gamma f_1 P_J = f_2 P_J,$$

which implies that $\lambda \in (f_2 P_J)(O_S)$.

Let $\Lambda_1 \subseteq P_J(O_S)$ be a finite index subgroup such that $(\gamma_0 f_1) \Lambda_1 (\gamma_1 f_1)^{-1}$ is contained in $(\gamma f_1 P_J)(O_S)$ and let $g_1, \ldots, g_m$ be a set of right coset representatives for $\Lambda_1$ in $P_J(O_S)$.

Let $\Lambda_2 \subseteq (f_2 P_J)(O_S)$ be a finite index subgroup such that $f_2^{-1} \Lambda_2 f_2$ is contained in $P_J(O_S)$ and let $h_1, \ldots, h_l$ be a set of right coset representatives for $\Lambda_2$ in $(f_2 P_J)(O_S)$.

Each $g_i$ is in $P_J(K)$, $\gamma f_1 P_J = f_2 P_J$, and $h_j \in (f_2 P_J)(K)$ for all $j$. Therefore, $f_2^{-1} h_j (\gamma_0 f_1) g_i$ normalizes, and hence is contained in, $P_J(K)$. We choose a bounded set $B' \subseteq P_J$ such that

$$\bigcup_{i,j} f_2^{-1} h_j (\gamma_0 f_1) g_i \subseteq B'.$$

As in the comments preceding Lemma 31, we may assume that

$$B' A_J^+(\sqrt{t}) \subseteq A_J^+(\sqrt{t}) B'.$$
We have the following inclusions of sets:

\[ f_2^{-1} \gamma f_1 \mathbf{P}_J(O_3)A^+_J((8\sqrt{I})) = f_2^{-1} \lambda (\gamma_0 f_1) \mathbf{P}_J(O_3)A^+_J((8\sqrt{I})) \]
\[ = \bigcup_i f_2^{-1} \lambda (\gamma_0 f_1) A_1 g_i A^+_J((8\sqrt{I})) = \bigcup_i f_2^{-1} \lambda (\gamma_0 f_1) A_1 (\gamma_0 f_1)^{-1} (\gamma_0 f_1) g_i A^+_J((8\sqrt{I})) \]
\[ \subseteq \bigcup_i f_2^{-1} \lambda (\gamma_0 f_1) \mathbf{P}_J(O_3)(\gamma_0 f_1) g_i A^+_J((8\sqrt{I})) = \bigcup_i f_2^{-1} \lambda (f_2 \mathbf{P}_J)(O_3)(\gamma_0 f_1) g_i A^+_J((8\sqrt{I})) \]
\[ = \bigcup_i f_2^{-1} (f_2 \mathbf{P}_J)(O_3)(\gamma_0 f_1) g_i A^+_J((8\sqrt{I})) = \bigcup_i f_2^{-1} A_2 f_2^{-1} h_j (\gamma_0 f_1) g_i A^+_J((8\sqrt{I})) \]
\[ = \bigcup_i f_2^{-1} A_2 f_2^{-1} h_j (\gamma_0 f_1) g_i A^+_J((8\sqrt{I})) = \bigcup_i \mathbf{P}_J(O_3) f_2^{-1} h_j (\gamma_0 f_1) g_i A^+_J((8\sqrt{I})) \]
\[ \subseteq \mathbf{P}_J(O_3) B'_J((8\sqrt{I})) \subseteq \mathbf{P}_J(O_3) A^+_J((8\sqrt{I})) B'. \]

Let \( B \) be as in Lemma 31. Then

\[ f_2^{-1} \gamma f_1 U_{\Phi(J)} \cdot \mathbf{M}_J(O_3)A^+_J(t) \subseteq f_2^{-1} \gamma f_1 \mathbf{P}_J(O_3)A^+_J((8\sqrt{I})) B \subseteq \mathbf{P}_J(O_3) A^+_J((8\sqrt{I})) B' B \]
\[ \subseteq U_{\Phi(J)} \cdot \mathbf{M}_J(O_3)A^+_J(t) B' B. \]

**Proof of Proposition 9.** For part (i), notice that \( \mathbf{M} \) is \( K \)-anisotropic. Therefore there is a bounded set \( B_M \subseteq M \) such that \( M = \mathbf{M}(O_3)B_M \). If \( B \) is as in Theorem 18, then we let \( B_0 = B_M B \). Thus,

\[ \mathbf{G}(O_3) F U M(O_3) A^+_M B_0 = \mathbf{G}(O_3) F U M(O_3) A^+_M B_M B = \mathbf{G}(O_3) F U M(O_3) B_M A^+_M B \]
\[ = \mathbf{G}(O_3) F U M A^+_M B = G. \]

For (ii), suppose \( B_n \) and \( N_n \) are given. Let \( Q = \gamma f_1 \mathbf{P}_J \) and \( Q' = \gamma f_1 \mathbf{P}_J \). Assume that \( Q \neq Q' \) and \( |I| = |J| = n \).

Let \( \gamma f \in A_Q \). If \( t > 1 \), then Lemma 33 shows that there is some bounded set \( B \subseteq G \) such that \( \gamma f U_{\Phi(J)} \cdot \mathbf{M}_J(O_3)A^+_J(t) B_n \) is contained in \( \gamma f_1 U_{\Phi(J)} \cdot \mathbf{M}_J(O_3)A^+_J(t) B_n \).

Therefore, \( R_Q(t) B_n \) is contained in \( \gamma f_1 U_{\Phi(J)} \cdot \mathbf{M}_J(O_3)A^+_J(t) B_n \).

Similarly, \( R_Q(t) B_n \) is contained in \( \gamma f_2 U_{\Phi(J)} \cdot \mathbf{M}_J(O_3)A^+_J(t) B_n \).

If \( f_2^{-1} f_2^{-1} \gamma f_1 \in \mathbf{P}_J(K) \) and \( I = J \) then \( f_2^{-1} f_2^{-1} \gamma f_1 \mathbf{P}_J = \mathbf{P}_J \), which contradicts that \( Q \neq Q' \). Thus, we can apply Lemma 32 to find some \( t_n > 1 \) such that \( f_2^{-1} f_2^{-1} \gamma f_1 \mathbf{P}_J(t_n) B_n \) is disjoint from \( f_2^{-1} f_2^{-1} \gamma f_1 \mathbf{P}_J(t_n) B_n \) where \( B_n \) is a neighborhood of \( 1 \) in \( G \) of radius \( N_n \).

For (iii), notice in the above that we could choose \( t_n \) to be arbitrarily large.

Let \( w \in W \) represent the longest element of the Weyl group so that \( \tau_{I,J,w} \) is the highest root with respect to \( \Phi^+ \) and \( U_{w,-} = U \). Then by Lemma 23, there is some \( t_n > 1 \) such that \( U_{\Phi(J)} \cdot A(\tau_{I,J,w}, t_n) \) is arbitrarily far from \( \mathbf{G}(O_3) \). Hence, \( U_{\Phi(J)} \cdot A^+_J(t_n) \), and thus \( \mathbf{M}_J(O_3)U_{\Phi(J)} \cdot A^+_J(t_n) \), is arbitrarily far from \( \mathbf{G}(O_3) \). Then by Lemma 20, \( U_{\Phi(J)} \cdot \mathbf{M}_J(O_3)A^+_J(t_n) \) is arbitrarily far from \( F^{-1} \mathbf{G}(O_3) \mathbf{G}(O_3) \), which proves this part of the proposition.
For (iv) and (v), let \( I \subseteq \Delta \). Let \( \gamma \in G(O_S), f \in F, u \in U_{\Phi(I)^+}, m \in M_I(O_S), \)
\( a \in A_I^+, \) and \( b \in B_n \). Furthermore, assume that \(|\alpha(a)| < 2n\) for some \( \alpha \in \Delta - I \). Let \( J = I \cup \alpha \).

There is a bounded neighborhood of the identity \( B_{I,\alpha} \subseteq A \) depending on \( 2n \) such that \( a \in A_J^+ B_{I,\alpha} \). Thus,

\[
\gamma f u m a b \in \gamma f U_{\Phi(I)^+} M_I(O_S) A_J^+ B_{I,\alpha} B_n.
\]

The \( K \)-group \( U_{\Phi(I)^+ \cap [J]^+} \) is unipotent, so there is some bounded set \( B_I \subseteq U_{\Phi(I)^+ \cap [J]^+} \)
\( \subseteq M_J \) containing the identity such that \( U_{\Phi(I)^+ \cap [J]^+} (O_S) B_J = U_{\Phi(I)^+ \cap [J]^+} \). Recall that \( M_I(O_S) \) normalizes \( U_{\Phi(I)^+} \). Therefore,

\[
U_{\Phi(I)^+} M_I(O_S) = M_I(O_S) U_{\Phi(I)^+} = M_I(O_S) U_{\Phi(I)^+} U_{\Phi(I)^+ \cap [J]^+} = U_{\Phi(I)^+} M_I(O_S) U_{\Phi(I)^+ \cap [J]^+} = U_{\Phi(I)^+} M_I(O_S) U_{\Phi(I)^+ \cap [J]^+} B_J = U_{\Phi(I)^+} M_I(O_S) B_J.
\]

Since \( B_J \subseteq M_J \) commutes with \( A_J^+ \), we have

\[
\gamma f u m a b \in \gamma f U_{\Phi(I)^+} M_J(O_S) A_J^+ B_J B_{I,\alpha} B_n.
\]

If we let \( B' \) be the product over \( I \) and \( \alpha \) of the sets \( B_J B_{I,\alpha} \), then we can let \( B_{n+1} = B' B_n \).

In the case when \( |I| = |\Delta| - 1 \), notice that for \( |J| = |\Delta| \) the groups \( U_{\Phi(J)^+} \) and \( A_J^+ \)
are trivial and \( M_J = G \), so

\[
\gamma f u m a b \in \gamma f G(O_S) B_{|\Delta|}.
\]

The lemma follows after enlarging \( B_{|\Delta|} \) in view of Lemma 20.

For (vi), suppose \( Q = \gamma f P_I \) for some \( \gamma \in G(O_S) \) and \( f \in F \). As in the proof
of (ii), Lemma 33 implies that there is a bounded set \( B \subseteq G \) such that \( R_Q(t_n) B_n \) is
contained in \( \gamma f U_{\Phi(I)^+} M_I(O_S) A_J^+ (t_n) B B_n \), and there is an obvious quasi-isometry from
\( \gamma f U_{\Phi(I)^+} M_I(O_S) A_J^+ (t_n) B B_n \) to the space \( U_{\Phi(I)^+} M_I(O_S) A_J^+ \) that satisfies the proposition.

\( \square \)

Acknowledgments. The original blueprint for this proof was developed at an AIM workshop in
September 2008. We would like to thank AIM as well as the co-organizers of that workshop, Nathan
Broaddus and Tim Riley, and the rest of the participants. We would also like to thank Shahar Mozes
for helpful conversations during that workshop.

Moreover, we thank Kai-Uwe Bux, Brendan Kelly, Amir Mohammadi, Dave Morris, and
Robert Young for helpful conversations, and the referee for pointing out some corrections.

Finally, we gratefully acknowledge the support of the National Science Foundation.
