Abstract

Immunoglobulin E (IgE) functions as a first-line defense against parasitic infections. However, aberrant production of IgE is known to be associated with various life-threatening allergic diseases. Superoxide dismutase 3 (SOD3) has been found to suppress IgE in various allergic diseases such as allergic conjunctivitis, ovalbumin-induced allergic asthma, and dust mite-induced atopic dermatitis-like skin inflammation. However, the role of SOD3 in the regulation of IgE production in B cells remains elusive. In this study, we investigated the effect of SOD3 on LPS/IL-4 and anti-CD40/IL-4-mediated secretion of IgE in murine B cells. Our data showed that SOD3 can suppress both LPS/IL-4 and antiCD40/IL-7-induced IgE secretion in B cells isolated from both wild-type (SOD3^+/+) and SOD3 knock-out (SOD3^−/−) mice. Interestingly, B cells isolated from SOD3^−/− mice showed higher secretion of IgE, whereas, the use of DETCA, a known inhibitor of SOD3 activity, reversed the inhibitory effect of SOD3 on IgE production. Similarly, SOD3 found to reduce the proliferation, IgE isotype switch, ROS level, and CCL17 and CCL22 productions in B cells. Furthermore, SOD3 was found to suppress both LPS/IL-4 and anti-CD40/IL-4-mediated activation of downstream signaling such as JAK1/JAK3, STAT6, NF-κB, p38, and JNK in B cells. Taken together, our data showed that SOD3 can be used as an alternative therapy to restrict IgE-mediated allergic diseases.

Introduction

Immunoglobulin E (IgE) is the immunoglobulin type that acts as a first-line defense against parasitic infections. However, inappropriate regulation of IgE is found to be associated with various allergic diseases and can lead to severe life-threatening anaphylaxis. Serum IgE levels are found to be elevated in various allergic diseases such as asthma, allergic rhinitis, atopic dermatitis, contact dermatitis, and urticaria. The production of IgE is tightly regulated by class switch recombination (CSR) and requires major two signals: T helper cell-B cell interaction through CD40L/CD40 accompanied by IL-4 secreted by activated T cells. The interaction of CD40L and CD40 leads to the activation of nuclear factor κB (NFκB), p38 mitogen-activated protein kinase (p38), and c-jun-NH2-kinase (JNK) whereas binding of IL-4 to its receptor complexes activates downstream Janus kinases (JAK1/JAK3) and the following signal transducer and activator of transcription 6 (STAT6) phosphorylation. These signals work synergistically for the transcription and synthesis of IgE. Therefore, NF-κB, p38, JNK, and JAK-STAT signaling pathway can be targeted to alleviate the inappropriate production of IgE and hyper IgE-mediated allergic syndrome.

Superoxide dismutase 3 (SOD3), also known as extracellular superoxide dismutase are responsible for the maintenance of redox homeostasis in the extracellular matrix of various tissues. Along with antioxidative properties, the anti-inflammatory function of SOD3-mediated through both enzymatic and non-enzymatic manner have been well established in various disease models. In addition, some studies also revealed the anti-allergic function of SOD3 in various allergic conditions. In experimental allergic conjunctivitis and ovalbumin-induced allergic asthma murine models, treatment with SOD3...
showed reduced serum level of OVA-induced IgE\(^9,12\). Similarly, treatment with SOD3 also found to suppress the serum IgE levels in house dust mite-induced atopic dermatitis-like skin inflammation\(^13\). Thus, SOD3 found to regulate the production of IgE during various allergic conditions. However, the direct role of SOD3 in regulating the production of IgE is still unclear.

In this study, we aimed to determine the effect of SOD3 on IgE production in B cells. Primary naive B cells were differentiated for IgE production and the effects of SOD3 on IgE production and underlying effects on signaling were investigated. Our data showed that SOD3 limits the IgE production in B cells with reduced proliferation and IgE isotype class switching. Thus, our study provides supportive information regarding the use of SOD3 in hyper-IgE-mediated allergic conditions.

**Results**

**Effect of SOD3 on IgE production in LPS/IL-4 and anti-CD40/IL-4-stimulated B cells**

Previously, SOD3 was found to suppress the serum IgE level during various allergic conditions\(^9,12,13\). Thus, we first aimed to determine the effect of SOD3 on IgE production in \textit{in vitro}. Here, we found that SOD3 significantly suppresses the production of IgE in B cells under both LPS/IL-4 and anti-CD40/IL-4 conditions (Fig. 1A and B). To further determine SOD3-mediated inhibition of IgE production, we isolated the B cells from whole body SOD3 knock-out (\(SOD3^{-/-}\)) mice and also used DETCA, a known inhibitor of SOD3 activity. Our data showed that the IgE production was relatively higher in B cells isolated from \(SOD3^{-/-}\) mice compared to wild-type (\(SOD3^{+/+}\)) mice and the use of SOD3 downregulates the release of IgE in both \(SOD3^{-/-}\) and \(SOD3^{+/+}\) mice. In addition, DETCA rescued the inhibitory effect of SOD3 on IgE production in both \(SOD3^{+/+}\) and \(SOD3^{-/-}\) mice under LPS/IL-4 and anti-CD40/IL-4 conditions (Fig. 1C and D).

**Effect of SOD3 on proliferation in LPS/IL-4 and anti-CD40/IL-4-stimulated B cells**

We next aimed to determine the effect of SOD3 on B cell proliferation as activated B cells are known to undergo proliferation. Here, we found that SOD3 significantly suppresses the B cell proliferation under both LPS/IL-4 and anti-CD40/IL-4 conditions (Fig. 2A and B). In addition, B cells isolated from \(SOD3^{-/-}\) mice were highly proliferative as compared to \(SOD3^{+/+}\) mice. The use of SOD3 inhibited the proliferation of B cells isolated from \(SOD3^{-/-}\) and \(SOD3^{+/+}\) mice. Moreover, DETCA reversed the inhibitory effect of SOD3 on B cell proliferation (Fig. 2C and D).
Effect of SOD3 on IgE class switch recombination in LPS/IL-4 and anti-CD40/IL-4-stimulated B cells

B cells undergo class switch recombination (CSR) process for IgE production. Thus, we next aimed to determine the effect of SOD3 on germline gene transcript (GLT), switch class transcript (SCT), and activation-induced cytidine deaminase (AID) at mRNA levels. Our data showed that SOD3 can significantly inhibit the B cells undergoing IgE isotype switching through the suppressed expression of GLT, SCT and AID (Fig. 3A and B). In addition, B cells isolated from SOD3−/− mice showed higher expression of CSR genes than that of SOD3+/+ mice. Moreover, SOD3 suppressed the expressions of genes involved in CSR, and DETCA tried to nullify the effect of SOD3 in both SOD3−/− and SOD3+/+ mice (Fig. 3C and D).

Effect of SOD3 on IgE secreting cells and ROS production in LPS/IL-4 and α-CD40/IL-4-stimulated B cells

Upon encountering with antigen and IL-4, activated B cells are known to differentiate into IgE secreting plasma cells. Thus, we evaluated the effect of SOD3 on the number of IgE secreting cells by ELISPOT assay. Here, we found that the number of IgE secreting cells was lower in SOD3-treated groups compared to both LPS/IL-4 and anti-CD40/IL-4 groups, whereas the number of IgE secreting cells were comparatively higher in DETCA-treated group than that of SOD3-treated groups (Fig. 4A and B). Engagement of B cell receptors with its ligand results in the production of ROS and can activate the downstream signaling for B cell activation and differentiation. Thus, we next determined the effect of SOD3 on superoxide anion produced during B cell activation. Our data showed that SOD3 significantly downregulates LPS/IL-4 and anti-CD40/IL-4-induced superoxide anions in B cells (Fig. 4C and D).

Effect of SOD3 on chemokines production in B cells

Naïve B cells are also known to release chemokines such as CCL22 and CCL17 upon activation. Thus, we next determined the effect of SOD3 on chemokines produced by activated B cells. Here, we found that SOD3 suppressed the expression levels of CCL17 and CCL22 chemokine in both LPS/IL-4 and anti-CD40/IL-4-stimulated B cells (Fig. 5A-D).

Effect of SOD3 on downstream signaling pathways

The interactions of IL-4 with its receptor are known to activate JAK-STAT signaling pathways, and the engagement of anti-CD40 and LPS with their respective receptors are known to activate multiple downstream signals. Thus, we examined the effect of SOD3 on various downstream signals. Here, we found that SOD3 suppressed IL-4-mediated activation of JAK1, JAK3, and STAT6 signals in B cells.
Similarly, we also determined the effect of SOD3 on LPS or anti-CD40-mediated activation of p38, JNK and NF-κB, and found that SOD3 significantly downregulates the activation of those molecules (Fig. 6A and B).

Discussion

Despite the important role of IgE in confronting helminthic infection, aberrant production of IgE found to be associated with several allergic diseases. The crosslinking of allergens to IgE antibodies on tissue mast cells or blood basophils results into the degranulation of these cells, and the release of inflammatory mediators, cytokines, and enzymes which mediate the clinical manifestation of various allergic conditions. Previously, SOD3 has been shown to reduce the serum IgE levels in various allergic diseases. However, the direct role of SOD3 in the production of IgE in B cells was not investigated. Here, we investigate the effect of SOD3 on IgE production and the effects on underlying signaling in B cells.

For the activation and differentiation of B cells into IgE secreting B cells, we used two different types of antigens. Lipopolysaccharides at high concentrations are capable of T-independent activation of B cells and the use of anti-CD40 ligand activates the B cells in T-dependent manner. The use of IL-4 stimulates the class switching from IgM to IgE producing B cells. In this study, we found that SOD3 significantly suppresses the release of IgE in B cells under both LPS/IL-4 and anti-CD40/IL-4 stimulating conditions. The higher production of IgE in B cells isolated from global SOD3 knock-out (SOD3−/−) mice compared to SOD3+/+ and the use of SOD3 limiting the release of IgE in both SOD3−/− and SOD3+/+ mice emphasized the important role of SOD3 in regulating the production of IgE. Similarly, the use of SOD3 activity inhibitor DETCA tried to rescue the inhibitory effect of SOD3 on IgE production in B cells isolated from both SOD3−/− and SOD3+/+ mice. However, DETCA could not completely reverse the inhibitory effect of SOD3 as SOD3 is also known to possess some effect in a non-enzymatic manner either through interacting with receptors or inhibiting the recruitment of NF-κB to the promoter site of target genes or inhibiting the translocation of TLR4 into lipid rafts.

SOD3 has been shown to suppress the proliferation of Th17 cells. Similarly, Th17 from SOD3−/− mice showed more proliferation than SOD3+/+ mice. In addition, cell cycle genes in MSCs under serum starvation and UVB-induced proliferation of melan-a cells were suppressed on SOD3 treatment. These studies emphasized the importance of SOD3 in the regulation of proliferation. The cross-linking of anti-CD40 ligand and LPS with their respective receptors induces a proliferative response in B cells. Upon antigenic stimulation, resting B cells promote from G0 and enter into G1 and S phase of the cell cycle, and undergo rapid proliferation. The antigenic-induced cell cycle entries are tightly regulated by MAPK and NF-κB signaling pathways. Our data showed that SOD3 can suppress the antigenic-mediated proliferation in B cells. However, these inhibitory effects of SOD3 on B cell proliferation may be
mediated through controlled regulation of downstream signaling pathways such as MAPK and NF-κB required for cell cycle progression.

Upon activation by antigen, stimulated B cells undergo class switch recombination (CSR) process in which the immunoglobulin heavy μ constant region exons (Cμ) are deleted and replaced by one of several sets of CH exons (e.g., Cγ, Cα, and Cε) to alter the isotype of the antibodies, resulting in the production of specific antibodies \(^{31,32}\). To undergo isotype switching for IgE production, B cells require two distinct signals \(^5\). The first signal is provided through binding of IL-4 to its receptor on the B cell which induces Cε germline transcripts (GLTs) \(^{25}\). The second signal is provided through ligation of CD40 on the B cell surface by CD40 ligand of T cells and triggers the deletional switch recombination to IgE \(^{33}\). Stimulation of B cells with anti-CD40 and IL-4 results into the activation of NF-κB and STAT6 transcription factors respectively, and functions to induce the production of Cε GLTs \(^{14,34}\). The Iε promoter contains the binding sites for STAT6 and NF-κB, and the binding of these transcription factors to the promoter results in the induction of Cε germline transcripts \(^6\). The activation-induced cytidine deaminase (AID) enzyme is required for CSR \(^{35}\). Ligations of CD40-induced NF-κB synergize with IL-4-induced STAT6 stimulates the expression of AID gene and proteins \(^{36}\). Our data showed that SOD3 significantly downregulates the expression levels of genes involved in CSR and AID. However, this inhibitory effect of SOD3 on IgE switch recombination may be mediated through reduced activation of downstream NF-κB and STAT6 transcription factors.

Upon activation, B cell is not much known to secrete various cytokines as T cells. The main cytokines produced by B cells are the chemokines such as CCL17 and CCL22 \(^{16–18}\). These chemokines function to recruit Th2 cells and in turn, Th2 cells produce cytokines required for B cell differentiation and antibody production \(^{37}\). Here, we found that treatment with SOD3 suppressed the secretion of chemokines CCL17 and CCL22 in B cells. This result illustrates the possible mechanism of reduced expression of IgE levels in vivo, where cytokines produced by Th2 cells and B cells work synergistically for the secretion of IgE.

Activated B cells are known to differentiate into antibody-secreting cells, leading to adaptive immune response through secretion of antibodies. Following ligand interaction with either Toll-like receptor (TLR) or with B cell receptor, B cells rapidly undergo proliferation and differentiate into antibody-secreting cells \(^{24,30}\). Our data showed that treatment with SOD3 inhibited both LPS/IL-4 and anti-CD40/IL-4-driven differentiation of IgE secreting cells analyzed with ELISpot assays. Similarly, engagement of B cell antigen receptors results into the upregulation of ROS, and the production of ROS is important for the differentiation and activation of downstream signaling events \(^{38,39}\). Here, we found that SOD3 suppressed the ROS levels in B cells. Thus, the inhibition of IgE secreting cells may be mediated through controlled regulation of LPS/IL-4 or anti-CD40/IL-4-induced activation of downstream signaling events.

Ligation of LPS and CD40 ligand with TLR4 and CD40 receptors respectively on B cells are known to activate downstream signaling pathways such as MAPK and NF-kB, and subsequently leads to the activation and proliferation of B cells \(^4,40\). Similarly, engagement of IL-4 with IL-4 receptor on B cells
recruit Janus kinases, JAK1 and JAK3, which causes the activation and nuclear translocation of STAT6 transcription factor $^{20,41}$. Binding of NF-κB and STAT6 transcription factors to their promoter regulate AID induction and IgE class switching $^{14,34}$. Several studies showed that SOD3 can significantly modulate the activation of cellular signaling events through both enzymatic and non-enzymatic manner $^{8–10,12,42}$. A study by Kwon et al showed that SOD3 inhibits the translocation of TLR4 into lipid rafts in dendritic cells (DCs) and also inhibited the recruitment of NF-κB to the promoter site of target genes in macrophages $^8$. Interestingly, we have shown that SOD3 can interact with IL-4 receptor in Th2 cells $^{11}$. Thus, suppressed activation of IL-4-mediated JAK-STAT signaling pathways may be mediated through interaction of SOD3 with IL-4 receptor. Taken together, we believe that SOD3 can modulate the activation of these signaling events and thereby controls the production of IgE and chemokines secretion in B cells (Fig. 7).

Along with antioxidant and anti-inflammatory functions, SOD3 also has been shown to possess immunomodulatory functions in various immune cells. SOD3 found to suppress DCs maturation through reduced expression of receptor proteins $^8$. Similarly, SOD3 also found to restrict T helper cell activation and differentiation $^{9,26}$. In addition, SOD3 found to inhibit the cathelicidin- and IgE-mediated degranulation of mast cells $^{13,42}$. These studies along with our current study emphasized the importance of SOD3 in regulating the immunomodulatory functions. However, extensive studies must be carried out for the effective use of SOD3 as an alternative treatment for IgE-mediated allergic conditions.

**Materials And Methods**

**B cell isolation and treatment**

All procedure of animal research were performed in accordance with the Laboratory Animals Welfare Act, the Guide for the Care and Use of Laboratory Animals and the Guidelines and Policies for Rodent experiment provided by the IACUC (Institutional Animal Care and Use Committee) in school of medicine, The Catholic University of Korea (Approval number: CUMS-2019-0285-03). Following the approval from The Catholic Ethics Committee of Catholic University of Korea, primary B cells were isolated from mouse spleen of C57/BL6 wild-type (SOD3$^{+/+}$) and whole body SOD3 knock-out (SOD3$^{-/-}$) mice using the MACS B cell isolation kit (130-090-862, Miltenyi Biotec, Teterow, Germany) following manufacturer instructions. Purified B cells were then rested at least two hours on ice and then $2 \times 10^5$ B cells were cultured in flat-bottom 96-well plates. The cells were cultured in Roswell Park Memorial Institute (RPMI)-1640 medium (CA059-050; Gendepot, Houston, Tx) supplemented with 10 % fetal bovine serum, 100 U/mL penicillin, and 100 µg/mL streptomycin (CA 005-010; Gendepot) at 37°C in a humidified incubator.

For experimental setup, isolated B cells were pre-treated with recombinant human SOD3 (rh SOD3; 100U/mL, 200U/mL, and 300U/mL) for 1 hour. The cells were then treated with a combination of either 10 µg/mL of LPS (L6529, Sigma-Aldrich) and 10 ng/mL of rh mouse IL-4 (MIL 4-25, JW CreaGene Inc.) or 5 µg/mL of anti-CD40 (Cyt-472, Prospec) and 10 ng/mL of rh mouse IL-4 (MIL 4-25, JW CreaGene Inc.) for 5 days.
ELISA of IgE production

The levels of IgE release were measured from cell-free supernatant by ELISA method using IgE mouse ELISA kit (ab157718, abcam) according to the manufacturer’s instructions. Briefly, 100 µl of each standard and samples were added into pre-coated wells and were incubated at room temperature for 30 minutes. After incubation, the contents of the well were aspirated and washed with the provided 1X wash buffer for 5 times. Following washing, 100 µl of 1X enzyme-antibody conjugated were added to each well and the plates were incubated in dark for 30 minutes. The plates were then washed and 100 µl of TMB substrate solution were added into each well and incubated in dark at room temperature for 10 minutes. After 10 minutes, 100 µl of stop solution were added into each well, and absorbance was taken at 450 nm.

Cell proliferation assay

Isolated naïve B cells were plated in 96-well plates at 2×10^5 cells/mL in 100 µL per well of culture media. Cells were then pre-treated with SOD3 for 1 hour followed by treatment with either LPS/IL-4 or anti-CD40/IL-4 for 5 days. Cell proliferation was measured with BrdU cell proliferation assay kit (Catalog No. 2750, Millipore) following the manufacturer’s instruction.

ELISpot assay

The number of IgE secreting cells were determined by using Mouse IgE ELISpotBASIC kit (3815-2A, MABTECH AB, USA) following the manufacturer’s instructions. Briefly, provided PVDF plates were activated with 50 µl of 70% ethanol per well for 2 minutes. The plates were washed 5 times with sterile water and incubated overnight with 100 µl of anti-IgE antibody at 4oC. Next day, coated antibody were aspirated and washed with sterile water. The wells were then blocked with 200 µl of culture medium and incubated at room temperature for 30 minutes. After blocking, cell suspension with indicated stimuli were added to each well and incubated for 5 days at 37°C in humidified chamber with 5% CO₂. After 5 days of incubation, the cells were removed and the wells were washed 5 times with 200 µl of PBS/well. Detection antibody were added to each well and incubated at room temperature for 2 hours. The wells were then incubated with 100 µl of streptavidin-ALP for 1 hour at room temperature. Substrate solution was added and developed distinct spots were analyzed with microscope.

ROS measurement

Isolated B cells were first pre-treated with 5 µM of dihydroethidium (DHE) (D1168, Invitrogen) and incubated in dark at 37°C for 30 minutes. The cells were then treated with SOD3 (200 U/mL), and LPS/IL-4 or anti-CD40/IL-4 for 10, 30, and 60 minutes. Fluorescent were measured at an excitation of 500 nm and emission of 600 nm by fluorimeter.
Western blot analysis

Cells were harvested after 5 days of incubation at 37°C in humidified incubator and were lysed in ice-cold radioimmunoprecipitation (RIPA) lysis buffer (Catalog No. 89901, Thermo Scientific, Rockford, USA) containing protease and phosphatase inhibitor cocktails (Roche Diagnostic, Germany). Protein concentrations was determined by BCA protein assay Kit (Catalog No. 23225, Thermo Scientific, Rockford, USA) as described by manufacturer instructions. Equal amounts of proteins were separated by sodiumdodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to polyvinylidene difluoride membrane (PVDF). After blocking, membranes were incubated with primary antibodies such as p-p38 (9211S, Cell Signaling), p38 (9212S, Cell Signaling), P-JNK (9251S, Cell Signaling), JNK (9252S, Cell Signaling), P-JAK1 (3331S, Cell Signaling), JAK1 (3332S, Cell Signaling), P-JAK3 (5031S, Cell Signaling), JAK3 (8863S, Cell Signaling) P-STAT6 (9361S, Cell Signaling), STAT6 (9362S, Cell Signaling), p-NF-κBp65 (SC-136548, Santa Cruz), NF-κBp65 (SC-109, Santa Cruz) and GAPDH (SC-32233, Santa Cruz) at 1:1000 dilutions for overnight at 4°C. Membranes were then washed and incubated with horseradish-peroxidase conjugated secondary antibodies (1:5000 dilutions) for 2 hours at room temperature. The blots were then detected with western blot detection kit (WesternBrightTMECL, USA).

cDNA synthesis and reverse-transcriptase PCR (RT-PCR) analysis

Total RNA was isolated from cells by using TRIzol reagent (Catalog No. 15596018, Life Technologies, Invitrogen). Complementary DNA was synthesized from 1 μg of total RNA using the PrimeScript™ RT reagent Kit (RR047A,Clontech Takara Bio INC, Japan) and RT-PCR was performed using LightCycler 96 (Roche Diagnostics, Mannheim, Germany). Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) was used as an endogenous control. The amplified products were analyzed by electrophoresis in a 2% agarose gel. The used primers and their sequences can be found in supplementary sections (Figure S5).

SOD3 purification and activity assay

SOD3 was purified as previously described 43. Briefly, SOD3 plasmids were transfected into human embryonic kidney cells (HEK293E) and media were collected after every 48 hours. The collected media were filtered and loaded on HiTrap Chelating HP column (GE Healthcare). The recombinant SOD3 was verified by western blot with SOD3 antibody as previously described 44. SOD3 activity in the culture medium was analyzed by SOD assay kit-WST as per the manufacturer's instruction (S311, Dojindo Molecular Technologies, Japan).

Statistical analysis
Statistical differences were analyzed by one-way analysis of variance (ANOVA) followed by Tukey test. All results represent three independent experiments. P <0.05 was considered statistically significant (*p < 0.05, **p < 0.01, ***p < 0.001).
