Korn’s inequality and John domains

Renjin Jiang and Aapo Kauranen

June 21, 2017

Abstract: Let $\Omega \subset \mathbb{R}^n$, $n \geq 2$, be a bounded domain satisfying the separation property. We show that the following conditions are equivalent:

(i) $\Omega$ is a John domain;

(ii) for a fixed $p \in (1, \infty)$, the Korn inequality holds for each $u \in W^{1,p}(\Omega, \mathbb{R}^n)$ satisfying $\int_{\Omega} \frac{\partial u_i}{\partial x_j} - \frac{\partial u_j}{\partial x_i} \, dx = 0$, $1 \leq i, j \leq n$,

$$(K_p) \quad \|D u\|_{L^p(\Omega)} \leq C_K(\Omega, p) \|\varepsilon(u)\|_{L^p(\Omega)};$$

(ii') for all $p \in (1, \infty)$, $(K_p)$ holds on $\Omega$;

(iii) for a fixed $p \in (1, \infty)$, for each $f \in L^p(\Omega)$ with vanishing mean value on $\Omega$, there exists a solution $v \in W^{1,p}_0(\Omega, \mathbb{R}^n)$ to the equation $\text{div} \, v = f$ with

$$(DE_p) \quad \|v\|_{W^{1,p}(\Omega, \mathbb{R}^n)} \leq C(\Omega, p) \|f\|_{L^p(\Omega)};$$

(iii') for all $p \in (1, \infty)$, $(DE_p)$ holds on $\Omega$.

For domains satisfying the separation property, in particular, for finitely connected domains in the plane, our result provides a geometric characterization of the Korn inequality, and gives positive answers to a question raised by [Costabel & Dauge, Arch. Ration. Mech. Anal. 217 (2015), 873-898] and a question raised by [Russ, Vietnam J. Math. 41 (2013), 369-381]. For the plane, our result is best possible in the sense that, there exist infinitely connected domains which are not John but support Korn’s inequality.

1 Introduction

Let $\Omega$ be a bounded domain in $\mathbb{R}^n$, $n \geq 2$. Throughout the paper, a domain is a connected, open and proper subset of $\mathbb{R}^n$, $n \geq 2$. Let $p \in (1, \infty)$. For each vector field $v = (v_1, \cdots, v_n) \in W^{1,p}(\Omega, \mathbb{R}^n)$, let $Dv$ denotes its (distributional) gradient matrix, $\varepsilon(v)$ denotes the symmetric part of $Dv$, i.e., $\varepsilon(v) = (\varepsilon_{ij}(v))_{1 \leq i, j \leq n}$ with

$$\varepsilon_{ij}(v) = \frac{1}{2} \left( \frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i} \right).$$

- Key words and phrases. Korn inequality, John domain, separation property, divergence equation
and \(\kappa(v) = \{\kappa_{i,j}(v)\}_{1 \leq i,j \leq R}\) be the anti-symmetric part of \(Dv\) as \(\frac{1}{2}(Dv - Dv^T)\).

Korn’s (second) inequality states that, if each \(\kappa_{i,j}(v)\) is of vanishing mean value on \(\Omega\), then there exists \(C_K > 0\) such that

\[
(K_p) \quad \|Dv\|_{L^p(\Omega)} \leq C_K \|\varepsilon(v)\|_{L^p(\Omega)}.
\]

The Korn inequality \((K_p)\) is a fundamental tool in the theory of elasticity and fluid mechanics; we refer the reader to \([1, 8, 10, 12, 14, 19, 25]\) and the references therein.

The study of Korn inequality on domains has a long history. Friedrichs \([14]\) proved the Korn inequality \((K_p)\) for \(p = 2\) on domains with a finite number of corners or edges on \(\partial\Omega\). Nečas \([30]\) proved the Korn inequality on bounded Lipschitz domains. Kondratiev and Oleinik \([25]\) studied the Korn inequality \((K_2)\) on star-shaped domains. Recently, Acosta, Durán and Muschietti \([1]\) proved the Korn inequality (in a different form than \((K_p)\)) holds for all \(p \in (1, \infty)\) on John domains (see Definition 1.3 below). We refer the reader to \([2, 3, 7, 8, 11, 21, 29, 31, 37]\) for more studies on the Korn inequality. It is worth to mention that the Korn inequality \((K_p)\) fails for \(p = 1\) even on a cube; see the examples from \([9, 33]\).

Recently, there have been some studies concerning the Korn inequality for more irregular domains, such as Hölder domains and \(s\)-John domains with \(s > 1\). It turns out the Korn inequality \((K_p)\) does not hold for any \(1 < p < \infty\) on these domains, and instead there are weighted versions of the Korn inequality; see \([2, 3, 21]\) for instance.

Then one may wonder, is John condition also necessary for domains to support the Korn inequality? Generally speaking, one may ask the following question.

**Question 1.1.** What is the geometric counterpart of the Korn inequality \((K_p)\)? Is there a necessary and sufficient geometric condition on the domain under consideration for the Korn inequality to hold?

On the other hand, there are some inequalities that are known to be equivalent to the Korn inequality, on (regular) planar domains; cf. \([10, 20, 36]\). In \([20]\), Horgan and Payne proved that on simply connected regular domains in the plane, the Korn inequality \((K_2)\), the Friedrichs inequality, and the Babuška-Aziz inequality are equivalent to each other with equivalence of constants.

In what follows, for each \(p \in (1, \infty)\) the space \(L^p_0(\Omega)\) denotes the collection of all \(L^p\)-integrable functions on \(\Omega\) with vanishing mean value. Recall that, the Friedrichs inequality states that for all conjugate harmonic functions \(h, g\) on a plane domain \(\Omega\), if \(h, g \in L^2_0(\Omega)\), then it holds

\[
\|h\|_{L^2(\Omega)} \leq C\|g\|_{L^2(\Omega)};
\]

cf. \([10, 20, 36]\). The Babyška-Aziz inequality (cf. \([5, 10, 20]\)) for the divergence equation states that, for each \(f \in L^2_0(\Omega)\) there exists a solution \(v \in W^{1,p}_0(\Omega, \mathbb{R}^2)\) to the equation \(\text{div } v = f\) with

\[
\|v\|_{W^{1,2}(\Omega, \mathbb{R}^2)} \leq C\|f\|_{L^2(\Omega)}.
\]

Recently, Costabel and Dauge \([10]\) verified the equivalence of the Friedrichs inequality and the Babuška-Aziz inequality with equality of constants on bounded domains, without requiring any (smooth) regularity of the domain, and they asked the following question:
Question 1.2. Is Korn’s inequality equivalent to the Babuška-Aziz inequality, without requiring a priori (smooth) regularity on the domain under consideration?

The implication of Korn’s inequality from the Babuška-Aziz inequality is well-known (cf. [1, 10]), while the reverse part remains open.

Nečas [30] had proved $L^p$-version of the Babuška-Aziz inequality for $1 < p < \infty$ on Lipschitz domains. Acosta, Durán and Muschietti [1] extended solvability of the divergence equation on John domains in $\mathbb{R}^n$, $n \geq 2$, via a constructive approach. By developing a decomposition technique for John domains, Diening, Ružička and Schumacher [11] further obtained solvability of the divergence equation in weighted cases, and also weighted Korn’s inequality. Russ [34] asked if one can characterize domains for which the divergence equation with Dirichlet boundary condition is solvable. In [22], the authors with P. Koskela showed that on a bounded simply connected domain $\Omega$ in $\mathbb{R}^2$, the divergence equation is solvable in $W^{1,p}_0(\Omega, \mathbb{R}^2)$ ($1 < p < \infty$), if and only if $\Omega$ is a John domain. This implies that, in particular, on a bounded simply connected plane domain, the Babuška-Aziz inequality holds if and only if the domain is John.

Therefore, if Korn’s inequality is equivalent to the Babuška-Aziz inequality, then the domain in some sense has to be a John domain, and this will also answer our Question A. The main aim of this paper is to provide positive answers to Questions A and B, if the domain additionally satisfies a condition known as the separation property. This condition, which is defined below, is valid on every finitely connected plane domain.

Before moving further, let us first recall the definition of a John domain. This terminology was introduced in [28], but these domains were studied already by F. John [23]. In what follows, for each $x \in \Omega$, we denote by $\rho(x)$ the distance of $x$ to the boundary of $\Omega$, i.e., $d(x, \partial \Omega)$.

**Definition 1.3 (John domain).** A bounded domain $\Omega \subset \mathbb{R}^n$ with a distinguished point $x_0 \in \Omega$ is a John domain if there exists a constant $C_J > 0$ such that for all $x \in \Omega$, there is a curve $\gamma : [0, l(\gamma)] \to \Omega$ parametrised by arclength such that $\gamma(0) = x$, $\gamma(l(\gamma)) = x_0$, and $\rho(\gamma(t)) \geq C_J t$.

The definition says that each point in a John domain can be joined to the center point with a twisted cone. Clearly, the requirements for being a John domain are much weaker than that for being Lipschitz domains. In particular, every Lipschitz domain is a John domain and John domains may have fractal boundary (e.g., Von Koch snowflake domain).

An additional requirement on the domain, which we will rely on heavily, is the following separation property, which was introduced by Buckley and Koskela [6], where the separation property was used to prove the geometric counterpart of Sobolev-Poincaré inequalities.

**Definition 1.4 (Separation property).** A domain $\Omega \subset \mathbb{R}^n$ with a distinguished point $x_0$ has the separation property if there is a constant $C_S \geq 1$ such that the following holds: for each $x \in \Omega$, there is a curve $\gamma : [0, 1] \to \Omega$ with $\gamma(0) = x$, $\gamma(1) = x_0$, and such that for each $t$ either $\gamma([0, t]) \subset B := B(\gamma(t), C_S \rho(\gamma(t)))$ or each $\gamma \in \gamma([0, t]) \setminus B$ belongs to a different component of $\Omega \setminus \partial B$ than $x_0$. In the latter case, we call $B$ a separating ball, and call the union of components of $\Omega \setminus B$ not containing $x_0$ as $B$-end and denoted by $E_B$.

The domains satisfying this separation property cannot have a lot of boundary components, and they may have long tentacles but one cannot have flat cusps (see Section 6).
Notice that if a domain $\Omega$ has the separation property for some $C_s \geq 1$, then it has the separation property for any constant larger than $C_s$. It follows from the definitions that every John domain has the separation property. More generally, it is proved in [6] that, every domain $\Omega$, which is quasiconformally equivalent to a uniform domain (cf. Jones [24] or Section 6) has the separation property. In particular, any finitely connected plane domain has the separation property; see [6, p. 583] and Corollary 6.2.

Our main result below gives positive answers to Question 1.1, Question 1.2 and [34, Question 3], if the domain additionally satisfies the separation property.

**Theorem 1.5.** Let $\Omega$ be a bounded domain of $\mathbb{R}^n$, $n \geq 2$. Suppose that $\Omega$ satisfies the separation property. Then the following statements are equivalent:

(i) $\Omega$ is a John domain;

(ii) for a fixed $p \in (1, \infty)$, the Korn inequality holds for each $u \in W^{1,p}(\Omega, \mathbb{R}^n)$ satisfying

$$\int_\Omega k_{i,j}(u) \, dx = 0, \; 1 \leq i, j \leq n, \text{ as}$$

$$(K_p) \quad \|Du\|_{L^p(\Omega)} \leq C_K \|e(u)\|_{L^p(\Omega)};$$

(ii') the Korn inequality $(K_p)$ holds for each $p \in (1, \infty)$;

(iii) for a fixed $p \in (1, \infty)$, for all $u \in W^{1,p}(\Omega, \mathbb{R}^n)$ it holds that

$$(\tilde{K}_p) \quad \|Du\|_{L^p(\Omega)} \leq C_K \left\{ \|e(u)\|_{L^p(\Omega)} + \|Du\|_{L^p(\Omega)} \right\},$$

where $Q$ is a fixed cube compactly supported in $\Omega$;

(iii') the Korn inequality $(\tilde{K}_p)$ holds for each $p \in (1, \infty)$;

(iv) for a fixed $p \in (1, \infty)$, for each $f \in L^p_0(\Omega)$, there exists a solution $v \in W^{1,p}_0(\Omega, \mathbb{R}^n)$ to the equation $\text{div} v = f$ with

$$(DE_p) \quad \|v\|_{W^{1,p}(\Omega, \mathbb{R}^n)} \leq C_d \|f\|_{L^p(\Omega)};$$

(iv') $(DE_p)$ holds for each $p \in (1, \infty)$.

We want to stress that the statement of Theorem 1.5 does not hold without some additional assumption on the domain; see Example 1.7 and Example 1.8 below.

Notice that $(K_p)$ is equivalent to the following Korn inequality for all $u \in W^{1,p}(\Omega, \mathbb{R}^n)$,

$$(\tilde{K}_p) \quad \inf_{S=-S} \|Du - S\|_{L^p(\Omega)} \leq C_K \|e(u)\|_{L^p(\Omega)}.$$

The implication $(K_p) \Rightarrow (\tilde{K}_p)$ follows by applying $(K_p)$ to $u - s x$ for each $u \in W^{1,p}(\Omega, \mathbb{R}^n)$, where the elements $s_{i,j}$ of $S$ are chosen as $\int_\Omega k_{i,j}(u) \, dx$; the converse implication follows by noticing that for $u \in W^{1,p}(\Omega, \mathbb{R}^n)$ with $\int_\Omega k_{i,j}(u) \, dx = 0$, $\|k_{i,j}(u)\|_{L^p(\Omega)} \leq C(\Omega, p)\|k_{i,j}(u) - a\|_{L^p(\Omega)}$ for any $a \in \mathbb{R}$.

By [6, Theorem 1.1], any of the above seven conditions is further equivalent to a Sobolev-Poincaré inequality, as

$$\left( \int_\Omega |u - u_\Omega|^{p(p - 3)} \, dx \right)^{(n - p)/np} \leq C \left( \int_\Omega |\nabla u|^p \, dx \right)^{1/p},$$
for some $p \in [1, n)$, where $u_\Omega$ denotes the average of integral of $u$ on $\Omega$.

The implication $(i) \implies (iv)$ was proved in [1], where the separation property is not required. In [22], with Koskela, the authors have proven $(iv) \implies (i)$, except for $p = n \geq 2$, directly by using Poincaré inequality and Hardy inequality. Therefore, Theorem 1.5 improves also this result slightly.

The implication $(vi) \implies (ii), (iii)$ is well-known, we include a proof for completeness in Section 2. The main achievement of this paper is that we show that $(ii), (iii) \implies (i)$ is also true, if the domain satisfies the separation property, which holds in particular on finitely connected domain $\Omega$ in the plane by Corollary 6.2 below.

**Corollary 1.6.** Let $\Omega$ be a bounded finitely connected domain in $\mathbb{R}^2$. Then the following statements are equivalent:

(i) $\Omega$ is a John domain;

(ii) the Korn inequality $(K_p)$ holds for some $p \in (1, \infty)$;

(ii') the Korn inequality $(\tilde{K}_p)$ holds for each $p \in (1, \infty)$;

(iii) the Korn inequality $(\hat{K}_p)$ holds for some $p \in (1, \infty)$;

(iii') the Korn inequality $(\hat{K}_p)$ holds for each $p \in (1, \infty)$;

(iv) $(DE_p)$ holds for some $p \in (1, \infty)$;

(iv') $(DE_p)$ holds for each $p \in (1, \infty)$.

The result in dimension two is best possible in the sense that, our characterization of domains for the Korn inequality works for any finitely connected domains, meanwhile, one has

**Example 1.7.** There exist infinitely connected plane domains $\Omega$, which are not John domains, but the Korn inequalities $(K_p)$ and $(\tilde{K}_p)$ hold on $\Omega$ for all $p \in (1, \infty)$.

We remark that one cannot hope for exact analogues of Corollary 1.6 in dimensions $n \geq 3$, since the connectivity property is a much weaker condition in higher dimensions than it is in dimension two, and $\mathbb{R}^n$ is highly rigid when $n \geq 3$. This phenomenon happens in many areas, for instance, the problem for Sobolev extension domains, the Schoenfliess theorem fails in $\mathbb{R}^3$ and there are very few (quasi)conformal mappings in dimensions $n \geq 3$; see Jones [24]. Indeed, the following example shows even simple connectivity is not sufficient to deduce analogues of Corollary 1.6 in higher dimensions.

**Example 1.8.** There exist simply connected domains $\Omega \subset \mathbb{R}^n, n \geq 3$, which are not John domains, but the Korn inequalities $(K_p)$ and $(\tilde{K}_p)$ hold on $\Omega$ for all $p \in (1, \infty)$.

The above two examples are based on domains constructed in Buckley-Koskela [6], details will be given in Section 6.

Corollary 1.6 together with [10, Theorem 2.1] shows

**Corollary 1.9.** Let $\Omega$ be a bounded finitely connected domain in $\mathbb{R}^2$. Then the following statements are equivalent:

(i) $\Omega$ is a John domain;

(ii) The Korn inequality $(K_2)$ holds;

(iii) The Babuška-Aziz inequality holds;

(iv) The Friedrichs inequality holds.
Recall that, in [20], Horgan and Payne verified the equivalence of (ii), (iii), (iv) on simply connected regular domains in the plane, Costabel and Dauge [10] showed the equivalence of (iii), (iv) on bounded domains without any a priori regularity assumption. Our result above requires finite connectivity of underlying domains, and provides the extra geometric equivalence (i). However, the advantage of [10, 20] is that they have also the equivalence of constants.

The proof of Theorem 1.5, in particular, the proof of (ii), (iii) $\implies$ (i), will be divided into two steps. In the first step, we will give a geometric characterization of the John domains via controlling the measure of ends by separating balls. We expect such a geometric characterization will have independent interest. In the second step, we first construct good test functions, and then use the Korn inequalities and this characterization of John domains to conclude the claim.

The paper is organized as follows. In Section 2, we recall some known results on the divergence equation, and provide the proofs for the implications \((DE_p) \implies (K_q), (\tilde{K}_q), 1/p + 1/q = 1\), for completeness. In Section 3, we provide a geometric characterization of the John domains. In Section 4 and Section 5, we will prove (ii), (iii) $\implies$ (i) and complete the proof of Theorem 1.5.

In section 6, we will discuss the necessity of our assumption of the separation property and some related problems, and provide details for Example 1.7 and Example 1.8.

Throughout the paper, we denote by $C$ positive constants which are independent of the main parameters, but which may vary from line to line. For matrices $S \in \mathbb{R}^{n \times n}$ we use the norm $|S| := \max(|s_{ij}| : 1 \leq i, j \leq n)$.

## 2 The divergence equation and Korn inequality

In this section, let us recall the known results on the divergence equation and its applications to the Korn inequality. The following result was proved in [1]; see also [11] for a different proof.

**Theorem 2.1** ([1]). Let $q \in (1, \infty)$ and $\Omega \subset \mathbb{R}^n$ be a bounded John domain. Then, for each $f \in L^q_0(\Omega)$, there exists a solution $v \in W^{1,q}_0(\Omega, \mathbb{R}^n)$ to the equation $\text{div} \, v = f$ with

\[
(DE_q) \quad \|v\|_{W^{1,q}(\Omega, \mathbb{R}^n)} \leq C\|f\|_{L^q(\Omega)}.
\]

It is somehow standard to show that \((DE_q)\) implies the Korn inequalities \((K_p)\) and \((\tilde{K}_p)\), where $1/p + 1/q = 1$. We provide a proof for completeness.

**Lemma 2.2.** Let $\Omega \subset \mathbb{R}^n$ be a bounded domain, $p, q \in (1, \infty)$ be a Hölder conjugate pair. If \((DE_q)\) holds on $\Omega$, then the Korn inequalities \((K_p)\) and \((\tilde{K}_p)\) hold on $\Omega$.

**Proof.** Recall that $Du = \left(\frac{\partial u}{\partial x_i}\right)_{1 \leq i, j \leq n}$, $1 \leq i, j \leq n$, and $e(u) = (e_{i,j}(u))_{1 \leq i, j \leq n}$ with

\[
e_{i,j} = \frac{1}{2} \left( \frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right)
\]

and the identity

\[
(2.1) \quad \frac{\partial^2 u_j}{\partial x_j \partial x_k} = \frac{\partial e_{i,k}}{\partial x_j} + \frac{\partial e_{i,j}(u)}{\partial x_k} - \frac{\partial e_{j,k}(u)}{\partial x_i}.
\]
For each \( f \in L^2_0(\Omega) \), from assumption of (\( DE_q \)), we see that there exists a solution \( v \in W^{1,q}_0(\Omega, \mathbb{R}^n) \) to the equation \( \text{div} \, v = f \) with

\[
\|v\|_{W^{1,q}(\Omega, \mathbb{R}^n)} \leq C\|f\|_{L^2(\Omega)}.
\]

For each \( k \in \{1, 2, \cdots, n\} \), let \( v^k \) be the \( k \)-th component of \( v \). Using the identity (2.1) yields

\[
\left| \int_{\Omega} f(x) \left( \frac{\partial u_j}{\partial x_i} - \left( \frac{\partial u_j}{\partial x_i} \right)_\Omega \right) \, dx \right| = \left| \int_{\Omega} \text{div} \, v(x) \left( \frac{\partial u_j}{\partial x_i} - \left( \frac{\partial u_j}{\partial x_i} \right)_\Omega \right) \, dx \right|
\leq \sum_{i,j,k=1}^n \int_{\Omega} v^k(x) \left( \frac{\partial \epsilon_{ij}^k(u)}{\partial x_i} + \frac{\partial \epsilon_{ij}^k(u)}{\partial x_k} - \frac{\partial \epsilon_{ik}^j(u)}{\partial x_j} \right)(x) \, dx.
\]

A duality argument gives

\[
(2.2) \quad \left\| \frac{\partial u_j}{\partial x_i} - \left( \frac{\partial u_j}{\partial x_i} \right)_\Omega \right\|_{L^p(\Omega)} \leq C\|\epsilon(u)\|_{L^p(\Omega)}.
\]

**Proof of (\( K_p \)).** Suppose now \( \int_{\Omega} \kappa_{i,j}(u) \, dx = 0 \) for \( 1 \leq i, j \leq n \). The (2.2) implies that

\[
\left\| 2\kappa_{i,j}(u) \right\|_{L^p(\Omega)} \leq \left\| \frac{\partial u_j}{\partial x_i} - \left( \frac{\partial u_j}{\partial x_i} \right)_\Omega \right\|_{L^p(\Omega)} + \left\| \frac{\partial u_j}{\partial x_i} - \left( \frac{\partial u_j}{\partial x_i} \right)_\Omega \right\|_{L^p(\Omega)} \leq C\|\epsilon(u)\|_{L^p(\Omega)}.
\]

Then the Korn inequality (\( K_p \)) follows since

\[
\|Du\|_{L^p(\Omega)} \leq \|\epsilon(u)\|_{L^p(\Omega)} + \|\kappa(u)\|_{L^p(\Omega)} \leq C\|\epsilon(u)\|_{L^p(\Omega)}.
\]

**Proof of (\( \widetilde{K}_p \)).** Now for an arbitrarily fixed cube \( Q \subset \subset \Omega \), we choose a \( \psi \in C_0^\infty(Q) \) such that \( \text{supp} \psi \subset Q \), \( \int_Q \psi \, dx = 1 \) and \( \|\nabla \psi\| \leq C/\ell(Q)^{p+1} \). Write

\[
(2.3) \quad \frac{\partial u_j}{\partial x_i} = \frac{\partial u_j}{\partial x_i} - \left( \frac{\partial u_j}{\partial x_i} \right)_\Omega + \int_Q \left( \frac{\partial u_j}{\partial x_i} - \left( \frac{\partial u_j}{\partial x_i} \right)_\Omega \right) \psi \, dx + \int_Q \frac{\partial u_j}{\partial x_i} \psi \, dx.
\]

Then by the Hölder inequality, we obtain

\[
\left| \int_Q \left( \frac{\partial u_j}{\partial x_i} - \left( \frac{\partial u_j}{\partial x_i} \right)_\Omega \right) \psi \, dx \right| \leq C(p, Q, \Omega)\|\epsilon(u)\|_{L^p(\Omega)},
\]

and

\[
\left| \int_Q \frac{\partial u_j}{\partial x_i}(x)\psi(x) \, dx \right| \leq C(a, p, Q, \Omega) \left\| \frac{\partial u_j}{\partial x_i} \right\|_{L^p(Q)^n}.
\]
Combining (2.2), (2.3) and the above estimates, we obtain that

\[
\left\| \frac{\partial u_j}{\partial x_i} \right\|_{L^p(\Omega)} \leq C(p, \Omega, Q) \left\{ \|\varepsilon(u)\|_{L^p(\Omega)} + \left\| \frac{\partial u_j}{\partial x_i} \right\|_{L^p(Q)} \right\},
\]

which is

\[
(\tilde{K}_p) \quad \|Du\|_{L^p(\Omega)} \leq C(p, \Omega, Q) \left\{ \|\varepsilon(u)\|_{L^p(\Omega)} + \|Du\|_{L^p(Q)} \right\}.
\]

The proof is complete. \(\square\)

Theorem 2.1 together with Lemma 2.2 gives the following corollary.

**Corollary 2.3.** Let \(\Omega \subset \mathbb{R}^n\) be a bounded John domain. Then for each \(p \in (1, \infty)\), the Korn inequalities \((K_p)\) and \((\tilde{K}_p)\) hold on \(\Omega\).

### 3 A geometric characterization of John domains

In this section, assuming the separation property, we explore another characterization of the John condition. We shall show that a domain is John if and only if the measures of ends are controlled with measures of separating balls. Similar arguments have been previously used to show necessity of John condition in other contexts in [17] and [6]. For the proof we need the following lemma originally from [4, Lemma 3.1] and the well-known Whitney decomposition (see eg. [35]).

**Lemma 3.1 ([4]).** Let \(1 \leq b < \infty\) and let \(x_j\) be a sequence of nonnegative numbers such that for all \(k \in \mathbb{N}\)

\[
\sum_{j=k}^{\infty} x_j \leq bx_k.
\]

Then for every \(\alpha \in (0, 1]\) there exists a constant \(c \geq 1\), depending only on \(b, \alpha\), such that for all \(k \in \mathbb{N}\)

\[
\sum_{j=k}^{\infty} x_j^\alpha \leq cx_k^\alpha.
\]

**Lemma 3.2.** For any open proper subset \(\Omega \subset \mathbb{R}^n\) there exists a collection \(W = \{Q_j\}_{j \in \mathbb{N}}\) of countably many closed dyadic cubes such that

(i) \(\Omega = \bigcup_{j \in \mathbb{N}} Q_j\), and if \(k \neq j\), then the cubes have disjoint interiors, \((Q_j)^\circ \cap (Q_k)^\circ = \emptyset\),

(ii) \(\sqrt{n} \ell(Q_k) \leq \text{dist}(Q_k, \partial \Omega) \leq 4 \sqrt{n} \ell(Q_k)\) and

(iii) \(\frac{1}{4} \ell(Q_k) \leq \ell(Q_j) \leq 4 \ell(Q_k)\) whenever \(Q_k \cap Q_j \neq \emptyset\).

Remember that Whitney decompositions are not unique. The following statement holds for any fixed \(W\).
Proposition 3.3. Let $\Omega \subset \mathbb{R}^n$ be a domain satisfying the separation property with constant $C_s \geq 1$ and a distinguished point $x_0$. For each point $x \in \Omega$, there is a curve $\gamma$ connecting $x$ to $x_0$ that satisfies the separation property with constant $5C_s$, and for each Whitney cube $Q \in W$, the set $Q \cap \gamma$ has at most one component.

Proof. Let $x \in \Omega$ be a point and let $\gamma : [0, 1] \to \Omega$ with $\gamma(0) = x$, $\gamma(1) = x_0$ be a curve given by the separation condition. We may assume the curve $\gamma$ has no self-intersecting points, otherwise, if there exist $0 \leq r < t \leq 1$ such that $\gamma(r) = \gamma(t)$, then one can modify the curve $\gamma$ as $\tilde{\gamma} : [0, r] \cup [t, 1] \to \Omega$, and $\tilde{\gamma}$ is a curve that connects $x$ and $x_0$ satisfying the separation property with the constant $C_s$.

Now consider the collection $W_\gamma$ of all Whitney cubes that intersect $\gamma$. Notice that since $\gamma$ is a compact set in $\Omega$, such a collection $W_\gamma$ is finite. If for each $Q \in W_\gamma$, $Q \cap \gamma$ has at most one component, then we are done. Otherwise, for each cube $Q$ for which $Q \cap \gamma$ has more than one component, let $t_u = \sup\{t : \gamma(t) \in Q \}$ and $t_l = \inf\{t : \gamma(t) \in Q \}$, and replace the curve $\gamma|(t_l, t_u)$ by the line segment $\ell_{\gamma(t_l), \gamma(t_u)}$. In such a way, we obtain a new curve $\tilde{\gamma}$ connecting $x$ to $x_0$. After reparametrisation, we denote the curve by $\tilde{\gamma} : [0, 1] \to \Omega$.

Claim. The curve $\tilde{\gamma}$ connecting $x$ and $x_0$ satisfies the separation condition with constant $5C_s$.

In what follows, for convenience, denote $B(\gamma(t), C_s \rho(\gamma(t)))$ and $B(\tilde{\gamma}(t), 5C_s \rho(\tilde{\gamma}(t)))$ by $B_{\gamma,t}$ and $B_{\tilde{\gamma},t}$ respectively.

Let $t \in [0, 1]$. If $\tilde{\gamma}([0, t]) \subset B_{\tilde{\gamma},t}$, then the conclusion follows. Suppose that $\tilde{\gamma}([0, t]) \setminus B_{\tilde{\gamma},t} \neq \emptyset$.

**Case 1.** $\tilde{\gamma}(t) \in \gamma([0, 1])$.

Let $t_\gamma \in [0, 1]$ be such that $\gamma(t_\gamma) = \tilde{\gamma}(t)$. Notice that by the construction of $\tilde{\gamma}$, $\tilde{\gamma}([0, t]) \cap \gamma([0, t_\gamma])$ only contains line segments, whose endpoints belong to $\gamma([0, t_\gamma])$. From this we see that $\gamma([0, t_\gamma]) \setminus B_{\gamma,t_\gamma} \neq \emptyset$, otherwise we have $\tilde{\gamma}([0, t]) \subset B_{\gamma,t}$. Since $B_{\gamma,t} \supseteq B_{\gamma,t_\gamma}$ and $\gamma([0, t]) \setminus B_{\gamma,t} \neq \emptyset$, we have $\gamma([0, t_\gamma]) \setminus B_{\gamma,t_\gamma} \neq \emptyset$. By the separation property, each $y \in \gamma([0, t_\gamma]) \setminus B_{\gamma,t_\gamma}$ and $x_0$ belong to different component of $\Omega \setminus \partial B_{\gamma,t_\gamma}$. Hence, we see that each

$$y \in (\gamma([0, t_\gamma]) \setminus \tilde{\gamma}([0, t])) \setminus B_{\gamma,t} \subseteq (\gamma([0, t_\gamma]) \setminus \tilde{\gamma}([0, t])) \setminus B_{\gamma,t_\gamma} \subseteq (\gamma([0, t_\gamma]) \setminus \tilde{\gamma}([0, t])) \setminus B_{\gamma,t}$$

belongs to a different component of $\Omega \setminus \partial B_{\gamma,t}$ than $x_0$.

Now, if $y \in (\gamma([0, t]) \setminus \gamma([0, t])) \setminus B_{\gamma,t} \neq \emptyset$, then there is a line segment $\ell_{\gamma(t), \gamma(t_\gamma)} \setminus B_{\gamma,t} \neq \emptyset$ and $\ell_{\gamma(t), \gamma(t_\gamma)} \subset (\gamma([0, t]) \setminus \gamma([0, t]))$. For each $y \in \ell_{\gamma(t), \gamma(t_\gamma)} \setminus B_{\gamma,t}$, there is one end-point of $\ell_{\gamma(t), \gamma(t_\gamma)}$ which we assume to be $\gamma(t_l)$, that also belongs to $\ell_{\gamma(t), \gamma(t_\gamma)} \setminus B_{\gamma,t}$ and connects to $y$ in the segment. Since $\gamma(t_l) \in \gamma$ that belongs to a different component of $\Omega \setminus \partial B_{\gamma,t}$ than $x_0$, we find that the set $\ell_{\gamma(t), \gamma(t_\gamma)} \setminus B_{\gamma,t}$ belong to a different component of $\Omega \setminus \partial B_{\gamma,t}$ than $x_0$, as desired.

**Case 2.** $\tilde{\gamma}(t) \in \gamma([0, 1]) \setminus \gamma([0, 1])$.

By the construction of the curve $\tilde{\gamma}$, we see that there is a line segment $\ell_{\gamma(t), \gamma(t_\gamma)} \subset \gamma([0, 1])$, that contains $\tilde{\gamma}(t)$ and belongs to a Whitney cube $Q$. Notice that the length of $\ell_{\gamma(t), \gamma(t_\gamma)}$ is no bigger than $\sqrt{n} \ell(Q)$, which is no bigger than $\rho(\tilde{\gamma}(t))$ or $\rho(\gamma(t_l))$. Therefore, $\ell_{\gamma(t), \gamma(t_\gamma)} \subset B_{\gamma,t}$,

$$\rho(\gamma(t_l)) \leq d(Q, \partial \Omega) + \sqrt{n} \ell(Q) \leq 2 \rho(\tilde{\gamma}(t))$$

and

$$B_{\gamma,t} = B(\gamma(t), C_s \rho(\gamma(t))) \subset B(\tilde{\gamma}(t), 5C_s \rho(\tilde{\gamma}(t))) = B_{\tilde{\gamma},t}.$$
If \( y \in \tilde{\gamma}([0, t]) \setminus B_{\tilde{\gamma}, t} \) and \( y \in \gamma([0, 1]) \), then
\[
y \in \gamma([0, t]) \setminus B_{\tilde{\gamma}, t} \subset \gamma([0, t]) \setminus B_{\gamma, t}.
\]
Since \( \gamma \) satisfies the separation property, this implies that \( y \) and \( x_0 \) belong to different components of \( \Omega \setminus \partial B_{\gamma, t} \), and further \( y \) and \( x_0 \) belong to different components of \( \Omega \setminus \partial B_{\tilde{\gamma}, t} \).

If \( y \in \tilde{\gamma}([0, t]) \setminus B_{\tilde{\gamma}, t} \) and \( y \notin \gamma([0, 1]) \), then by the construction of the curve \( \tilde{\gamma} \) again, we see that there is a line segment \( \ell_{\gamma(t), \gamma(t_0)} \subset \tilde{\gamma}([0, t]) \) such that \( y \in \ell_{\gamma(t), \gamma(t_0)} \). Arguing as in Case 1, we see that there is one end-point of \( \ell_{\gamma(t), \gamma(t_0)} \), assuming that it is \( \gamma(t) \), that belongs to \( \tilde{\gamma}([0, t]) \setminus B_{\tilde{\gamma}, t} \) and connects to \( y \) in the segment.

Since \( \gamma(t_0) \in \tilde{\gamma}([0, t]) \setminus B_{\tilde{\gamma}, t} \) and \( \gamma(t_0) \in \gamma([0, 1]) \), we can conclude that \( y \) and \( \gamma(t_0) \) belong to the same component of \( \Omega \setminus \partial B_{\tilde{\gamma}, t} \), while \( x_0 \) belongs to another component, as desired. \( \square \)

**Theorem 3.4.** Let \( \Omega \subset \mathbb{R}^n \) be a domain satisfying the separation property. Then \( \Omega \) is a John domain if and only if there exists a positive constant \( C_E \) such that for every separating ball \( B \), it holds that
\[
|E_B| \leq C_E |B| \tag{3.1}
\]
for \( B \)–end \( E_B \).

**Proof.** It is quite standard to prove (3.1) assuming John condition (see [6, Theorem 2.1]). For the converse implication we modify the ideas from [26, p. 18] and [6].

Let \( x \in \Omega \) be a point and let \( \gamma : [0, 1] \to \Omega \) with \( \gamma(0) = x, \gamma(1) = x_0 \) be a curve given by the separation condition. From the previous proposition, we may assume that for each Whitney cube \( Q \) the intersection \( Q \cap \gamma \) has at most one component.

To prove that \( \Omega \) is a John domain it suffices to show that
\[
\rho(\gamma(t)) = d(\gamma(t), \partial \Omega) \geq C \text{ diam } (\gamma([0, t])),
\]
see [28, pp.385-386] or [32, pp.7-8].

If \( x \in B(x_0, \rho(x_0)) \), then one can take the line segment connecting \( x \) and \( x_0 \), and the conclusion is obvious. Suppose now \( x \notin B(x_0, \rho(x_0)) \). Consider the collection \( W_{\gamma} \) of all Whitney cubes that intersect \( \gamma \). Since for each Whitney cube \( Q \) in \( W_{\gamma} \), there is only one component in \( Q \cap \gamma \) by our reduction above, we can order them so that they form a chain \( \{Q_j\}_{j=0}^W \) with \( x_0 \in Q_0 \) and \( W \in \mathbb{N} \) depending on \( x \). Notice that each cube is only numbered once.

For each \( t \in [0, 1] \), let \( k_t \) be the smallest number such that \( \gamma(t) \in Q_{k_t} \). For the point \( \gamma(t), t \in [0, 1] \), the separation condition implies either \( \gamma([0, t]) \subset B_{\gamma, t} \), and \( \gamma(t) := B(\gamma(t), C_4 \rho(\gamma(t))) \), or every \( y \in \gamma([0, t]) \setminus B_{\gamma, t} \) and \( x_0 \) lie in different components of \( \Omega \setminus \partial B_{\gamma, t} \) than \( x_0 \).

**Case 1.** Suppose that the former case happens. Then \( \gamma([0, t]) \subset B_{\gamma, t} \), and we have for each \( r < t \) that
\[
\rho(\gamma(r)) \leq C_4 \rho(\gamma(t)) + \rho(\gamma(t)),
\]
and for each \( Q_j \in W_{\gamma} \) that contains \( \gamma(r) \),
\[
Q_j \subset B(\gamma(r), \sqrt{\rho(Q_j)}) \subset B(\gamma(r), \rho(\gamma(r))) \subset B(\gamma(t), (2C_4 + 1) \rho(\gamma(t))) \subset B(\gamma(t), 3C_4 \rho(\gamma(t))). \tag{3.2}
\]
This together with the definition of the chain \( \{Q_j\}_{j=0}^{W_i} \) implies that \( \bigcup_{j=k_t}^{W_i} Q_j \subset B(\gamma(t), 3C_s\rho(\gamma(t))) \), and hence,

\[
\sum_{j=k_t}^{W_i} \ell(Q_j)^n \leq C(n, C_s)\rho(\gamma(t))^n \leq C(n, C_s)\ell(Q_{k_t})^n.
\]

**Case 2.** Suppose that every \( y \in \gamma([0, t]) \setminus B_{\gamma,t} \) lies in a different component of \( \Omega \setminus \partial B_{\gamma,t} \) than \( x_0 \).

We claim that in this case

\[
\bigcup_{j=k_t}^{W_i} Q_j \subset E_{B_{\gamma,t}} \cup B(\gamma(t), (3 + 2 \sqrt{n}C_E)C_s\rho(\gamma(t))).
\]

Notice that in this case we have \( \gamma([0, t]) \subset E_{B_{\gamma,t}} \cup B_{\gamma,t} \). For the cubes \( \{Q_j\}_{j=k_t}^{W_i} \), if \( Q_j \cap \gamma([0, t]) \cap B_{\gamma,t} \neq \emptyset \), then the same argument as in proving (3.2) gives that \( Q_j \subset B(\gamma(t), 3C_s\rho(\gamma(t))) \subset E_{B_{\gamma,t}} \cup B(\gamma(t), (3 + 2 \sqrt{n}C_E)C_s\rho(\gamma(t))). \)

For each cube \( Q_j \) that \( Q_j \cap \gamma([0, t]) \cap B_{\gamma,t} = \emptyset \), there is \( r \in [0, t] \) such that \( \gamma(r) \in Q_j \) and \( \gamma(r) \in E_{B_{\gamma,t}} \). If \( Q_j \subset E_{B_{\gamma,t}} \), then we also have \( Q_j \subset E_{B_{\gamma,t}} \cup B(\gamma(t), (3 + 2 \sqrt{n}C_E)C_s\rho(\gamma(t))). \)

It remains to consider the case \( Q_j \setminus E_{B_{\gamma,t}} \neq \emptyset \). Notice that now \( Q_j \cap B_{\gamma,t} \neq \emptyset \). From Lemma 3.2 and \( \gamma(r) \in Q_j \), we deduce that

\[
\sqrt{n}\ell(Q_j) \leq \rho(\gamma(r)) < d(Q_j, \partial \Omega) + \sqrt{n}\ell(Q_j) \leq 5 \sqrt{n}\ell(Q_j).
\]

This implies that \( B(\gamma(r), \ell(Q_j)) \) is compactly contained in \( \Omega \), further, since the center \( \gamma(r) \) is in \( E_{B_{\gamma,t}} \), we can conclude that at least half of \( B(\gamma(r), \ell(Q_j)) \) belongs to \( E_{B_{\gamma,t}} \), and from the assumption that

\[
\frac{1}{2}|B(\gamma(r), \ell(Q_j))| \leq |B(\gamma(r), \ell(Q_j)) \cap E_{B_{\gamma,t}}| \leq |E_{B_{\gamma,t}}| \leq C_E|B_{\gamma,t}|,
\]

and therefore \( \ell(Q_j) \leq (2C_E)^{1/n}C_s\rho(\gamma(t)) \). This and \( Q_j \cap B_{\gamma,t} \neq \emptyset \) give \( Q_j \subset B(\gamma(t), 2 \sqrt{n}C_E C_s\rho(\gamma(t))) \), and hence completes the proof of

\[
\bigcup_{j=k_t}^{W_i} Q_j \subset E_{B_{\gamma,t}} \cup B(\gamma(t), (3 + 2 \sqrt{n}C_E)C_s\rho(\gamma(t))).
\]

Finally, by the non-overlap property of Whitney cubes, Lemma 3.2, we conclude that

\[
\sum_{j=k_t}^{W_i} \ell(Q_j)^n = \sum_{j=k_t}^{W_i} |Q_j| \leq |E_{B_{\gamma,t}}| + |B(\gamma(t), (3 + 2 \sqrt{n}C_E)C_s\rho(\gamma(t)))| \\
\leq C(C_s, n, C_E)\rho(\gamma(t))^n \leq C(C_s, n, C_E)\ell(Q_{k_t})^n.
\]

The estimates (3.3) and (3.4) with Lemma 3.1 imply that for all \( t \in [0, 1] \)

\[
\sum_{j=k_t}^{W_i} \ell(Q_j) \leq C \ell(Q_{k_t}).
\]

Since the cubes \( \{Q_t\}_{t \geq k_t} \) cover the curve \( \gamma([0, t]) \), we find that \( \text{diam} \gamma([0, t]) \leq C \rho(\gamma(t)) \) for all \( t \in [0, 1] \), as desired. \( \square \)
4 Korn inequality \((K_p)\) implies John condition

In this and the next section, we provide the proof of the main result of the paper.

**Theorem 4.1.** Let \(\Omega\) be a bounded domain of \(\mathbb{R}^n\), \(n \geq 2\). Let \(1 < p < \infty\). Suppose that for all \(v \in W^{1,p}(\Omega, \mathbb{R}^n)\) satisfying \(\int_{\Omega} \kappa_{i,j}(v) \, dx = 0\), \(1 \leq i, j \leq n\), it holds that

\[(K_p)\quad \|Dv\|_{L^p(\Omega)} \leq C_K \|\epsilon(v)\|_{L^p(\Omega)}.

Then if \(\Omega\) satisfies the separation property, \(\Omega\) is a John domain.

**Proof.** Suppose that \(\Omega\) satisfies the separation property w.r.t. \(x_0 \in \Omega\). Let \(Q\) be the Whitney cube such that \(x_0 \in \overline{Q} \subset \Omega\).

By Theorem 3.4 to show that \(\Omega\) is a John domain, it suffices to show that there exists an absolute constant \(C_E > 0\) such that for each separating ball \(B, B = B(z, r)\) with \(z \in \Omega\), its end \(E_B\), if exists, has the property \(|E_B| \leq C_E|B|\).

If \(B \cap Q \neq \emptyset\), then by \(B \cap \partial \Omega \neq \emptyset\) we see that \(r \geq \sqrt{n}(Q)/2\). In this case, it holds that \(|E_B| \leq |\Omega| \leq C(\Omega, \Omega)|B|\).

Suppose now that \(B \cap Q = \emptyset\). Let \(E_B\) be the \(B\)-end. If \(|B| \geq |Q|/(C^p 3^{n+2p})\), then it holds that \(|E_B| \leq |\Omega| \leq C(\Omega, Q, C_K)|B|\). Therefore we may assume that

\[|B| < \frac{|Q|}{C^p 3^{n+2p}}.\]

If \(E_B \subset B(z, 4r)\) or \(|E_B| \leq 4^p|B|\) then the conclusion is obvious. Otherwise, set

\[
\phi(x) := \begin{cases} 
0, & \forall x \in \Omega \setminus E_B; \\
1, & \forall x \in E_B \setminus B(z, 2r); \\
\frac{d(x, B(z, r))}{r}, & \forall x \in E_B \cap (B(z, 2r) \setminus B(z, r)).
\end{cases}
\]

Then \(\phi\) is a Lipschitz function, with Lipschitz constant being \(1/r\), that vanishes on \(B \cap \Omega\).

For each \(x = (x_1, \cdots, x_n) \in \Omega\), let \(v = (v_1, v_2, 0, \cdots, 0)\) with

\[
\begin{cases} 
v_1(x_1, \cdots, x_n) = (x_2 - z_2)\phi(x_1, \cdots, x_n), \\
v_2(x_1, \cdots, x_n) = (z_1 - x_1)\phi(x_1, \cdots, x_n),
\end{cases}
\]

where \(z = (z_1, \cdots, z_n)\) is the center of \(B\). Then for each \(x = (x_1, \cdots, x_n) \in E_B \setminus B(z, 2r),\)

\[
Dv(x) = \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ -1 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & 0 \\ \vdots \\ 0 & 0 & 0 & \cdots & 0 \end{pmatrix},
\]

\(Dv(x) = 0\) for all \(x \in \Omega \setminus E_B\) and

\[|Dv(x)| \leq 2r|\nabla \phi(x)| + \phi(x) \leq 3\]
for all \( x \in E_B \cap (B(z, 2r) \setminus B(z, r)) \).

Since now \(|E_B| > 4^2|B|, |E_B \setminus B(z, 2r)| \geq |E_B| - |2B| > 3|B(z, 2r)|\). Then from the construction of \( \mathbf{v} \) we conclude that

\[
\int_{\Omega} \frac{\partial v_1}{\partial x_2} - \frac{\partial v_2}{\partial x_1} \, dx = 2 \int_{E_B \setminus B(z, 2r)} dx + \int_{E_B \cap B(z, 2r)} \frac{\partial v_1}{\partial x_2} - \frac{\partial v_2}{\partial x_1} \, dx > 0,
\]

since \( \int_{E_B \cap B(z, 2r)} \frac{\partial v_1}{\partial x_2} - \frac{\partial v_2}{\partial x_1} \, dx > -6|B(z, 2r)| \). Choose a vector field \( \mathbf{w} \) on \( \Omega \) as

\[
\mathbf{w}(x) = \mathbf{w}(x_1, \cdots, x_n) = (-\hat{C}x_2, \hat{C}x_1, 0, \cdots, 0),
\]

where \( \hat{C} \) satisfies

\[
2\hat{C}|\Omega| = \int_{\Omega} \frac{\partial v_1}{\partial x_2} - \frac{\partial v_2}{\partial x_1} \, dx.
\]

Now set \( \mathbf{u} = \mathbf{v} + \mathbf{w} \). One has that \( \mathbf{u} = (u_1, u_2, 0, \cdots) \), where \( u_i = v_i + w_i, i = 1, 2, \) is Lipschitz continuous on \( \Omega \) and satisfies

\[
\int_{\Omega} \frac{\partial u_1}{\partial x_2} - \frac{\partial u_2}{\partial x_1} \, dx = \int_{\Omega} \frac{\partial v_1}{\partial x_2} - \frac{\partial v_2}{\partial x_1} \, dx - 2\hat{C}|\Omega| = 0.
\]

Applying the Korn inequality \((K_p)\) to \( \mathbf{u} \), and noticing that \( \epsilon(\mathbf{w}) \equiv 0 \), we obtain

\[
\|D\mathbf{u}\|_{L^p(\Omega)} \leq C_K\|\epsilon(\mathbf{u})\|_{L^p(\Omega)} = C_K\|\epsilon(\mathbf{v})\|_{L^p(\Omega)} \leq 3C_K|B(z, 2r)|^{1/p}.
\]

By the construction of \( \mathbf{v} \) we have \( \mathbf{v} = 0 \) on \( \Omega \setminus E_B \), and therefore,

\[
\hat{C}|\Omega|^{1/p} \leq \hat{C}|\Omega \setminus E_B|^{1/p} \leq \|D\mathbf{u}\|_{L^p(\Omega)} \leq 3C_K|B(z, 2r)|^{1/p} < 3C_K \left( \frac{2^n|\Omega|}{C_K^{3n+2p}} \right)^{1/p}.
\]

From this, we see that \( \hat{C} < 1/3 \). By this, \((4.4)\) and \((4.3)\), we can conclude that

\[
\frac{2^p}{3^p}|E_B \setminus B(z, 2r)| \leq \|D\mathbf{u}\|_{L^p(\Omega)} \leq 3^pC_K^p|B(z, 2r)|.
\]

Hence, we find that \( |E_B \setminus B(z, 2r)| \leq 3^{2p+1}C_K^p|B| \) and hence, \( |E_B| \leq C(n, C_K, p)|B| \). Now applying Theorem \([5,4]\) we finally obtain that \( \Omega \) is a John domain. \( \square \)

### 5 Korn inequality \((\hat{K}_p)\) implies John condition

In this section, we show that the Korn inequality \((\hat{K}_p)\) also implies John condition, and therefore complete the proof of Theorem \([1,5]\). This requires little more work than the first implications. For the proof we need the following lemma which is well-known for the experts but it seems that there are no proofs published so far.

**Lemma 5.1.** Let \( \Omega \subset \mathbb{R}^n \) be a domain satisfying the separation property with constant \( C_s \) with respect to the distinguished point \( x_0 \). Let \( x \in \Omega \). Then \( \Omega \) satisfies the separation property also with respect to the distinguished point \( x \).
Proof. We claim that if the point $x_0$ qualifies for a distinguished point in the separation property, then every point in $B(x_0, \rho(x_0)/1000)$ qualifies for a distinguished point with constant $2C_d$.

By connectedness of $\Omega$, it suffices to prove this claim. Indeed, letting $E$ be the set of all points qualifying as distinguished points, the claim yields that $E$ is open. Suppose that $F := \Omega \setminus E \neq \emptyset$. Then there exists $y_0 \in \partial E \cap F$. Take $\tilde{y}_0 \in E$ with $|y_0 - \tilde{y}_0| < \frac{\rho(y_0)}{1000}$. Then

$$|y_0 - \tilde{y}_0| < \frac{\rho(y_0)}{1000} < \frac{1}{100000} \left(\rho(y_0) + |y_0 - \tilde{y}_0|\right),$$
and $|y_0 - \tilde{y}_0| < \frac{\rho(y_0)}{9990}$. This implies that $y_0 \in E$, since $y_0 \in B(\tilde{y}_0, \frac{\rho(y_0)}{1000})$. This is a contradiction with our choice of $y_0$, therefore, $F = \emptyset$, and $E = \Omega$.

Let us prove the claim. Take a point $x \in B(x_0, \rho(x_0)/1000)$. For any point $y \in \Omega$ there exists a curve $\tilde{y}$ joining $x_0$ to $y$ satisfying the condition in the definition of the separation condition. Denote by $\gamma$ the composition of $\tilde{y}$ and line segment $\ell_{x, x_0}$ joining $x$ and $x_0$. After a reparametrization we have $\gamma(0) = y$ and $\gamma(1) = x$.

Take a point $w = \gamma(t)$ on the curve $\gamma$. If this point lies on the line segment $\ell_{x, x_0}$ then we have $\rho(w) \geq \rho(x_0)$ and, therefore, $x_0 \in B(w, 2C_d \rho(w))$. This implies the required condition.

If the point $w$ lies on the curve $\tilde{y}$ then we have $w = \tilde{y}(t')$ for some $t'$. Since $\tilde{y}$ is the curve given by the separation condition we have either $\tilde{y}([0, t']) \subset B(w, C_d \rho(w))$ or every point in $\tilde{y}([0, t']) \setminus B(w, C_d \rho(w))$ belongs to a different component of $\Omega \setminus \partial B(w, C_d \rho(w))$ than $x_0$. In the former case we have $\tilde{y}([0, t']) \subset B(w, 2C_d \rho(w))$.

In the latter case, there is nothing to prove if $x \in B(w, 2C_d \rho(w))$. For the remaining case, i.e., $x \notin B(w, 2C_d \rho(w))$, let us argue by contradiction. Assume there exists $z \in \tilde{y}([0, t']) \setminus B(w, 2C_d \rho(w))$ belongs to the same component of $\Omega \setminus \partial B(w, 2C_d \rho(w))$ as $x$. This implies that $x$ and $z$ belong to a common component of $\Omega \setminus \partial B(w, C_d \rho(w))$, and furthermore, $x$ and $z$ belong to a different component than $x_0$. Since the line segment $\ell_{x, x_0}$ is contained in $\Omega$, it follows $\ell_{x, x_0} \cap \partial B(w, C_d \rho(w)) \neq \emptyset$. Since $x \notin B(w, 2C_d \rho(w))$, we find that

\begin{equation}
C_d \rho(w) \leq |x - x_0| < \rho(x_0)/1000.
\end{equation}

On the other hand, $B(w, C_d \rho(w))$ intersects $\partial \Omega$ and, thus, it holds $\rho(x_0) \leq |x_0 - w| + C_d \rho(w)$. This with (5.1) gives $|x_0 - w| > 9999 \rho(x_0)/1000$.

Notice that now, $B(w, 2C_d \rho(w)) \cap B(x_0, \rho(x_0)/2) = \emptyset$, since for each $\tilde{z} \in B(x_0, \rho(x_0)/2)$, it holds

$$|\tilde{z} - w| \geq |w - x_0| - |x_0 - \tilde{z}| > 999 \rho(x_0)/1000 - \rho(x_0)/2 > 2 \rho(x_0)/5 > 2C_d \rho(w).$$

This is a contradiction with $\ell_{x, x_0} \cap \partial B(w, C_d \rho(w)) \neq \emptyset$ and $\ell_{x, x_0} \subset B(x_0, \frac{\rho(x_0)}{1000})$. Therefore, there is no such $z$, that is, each $z \in \tilde{y}([0, t']) \setminus B(w, 2C_d \rho(w))$ belongs to a different component of $\Omega \setminus \partial B(w, 2C_d \rho(w))$ than $x$. The proof is complete.

With the help of above lemma, we are able to complete our proof.

**Theorem 5.2.** Let $\Omega$ be a bounded domain of $\mathbb{R}^n$, $n \geq 2$. Let $1 < p < \infty$ and $Q \subset \subset \Omega$ be a closed cube. Suppose that for all $v \in W^{1,p}(\Omega, \mathbb{R}^n)$ it holds that

\begin{equation}
\left(\tilde{K}_p\right) \quad \|Dv\|_{L^p(\Omega)} \leq C \left(\|v\|_{L^p(\Omega)}^p + \|Dv\|_{L^p(Q)}^p\right).
\end{equation}

Then if $\Omega$ satisfies the separation property, $\Omega$ is a John domain.
Proof. Suppose that $\Omega$ satisfies the separation property w.r.t. $x_0 \in \Omega$. Then by the above lemma, $\Omega$ satisfies the separation property w.r.t. $x_Q \in Q$, where $x_Q$ is the center of $Q$.

By Theorem 3.4, to show $\Omega$ is a John domain, it suffices to show that there exists an absolute constant $C_\varepsilon > 0$ such that for each separating ball $B$, $B = B(z, r)$ with $z \in \Omega$, its end $E_B$, if exists, then $|E_B| \leq C_\varepsilon|B|$.

If $B \cap Q \neq \emptyset$, then by $B \cap \partial\Omega \neq \emptyset$ we see that $r \geq \text{dist}(Q, \partial\Omega)/2$. In this case, it holds that $|E_B| \leq |\Omega| \leq C(\Omega, Q)|B|$. 

Suppose now $B \cap Q = \emptyset$. Let $E_B$ be the $B$-end. If $E_B \subset B(z, 4r)$ or $|E_B| \leq 4^n|B|$, then the conclusion is obvious. Otherwise, let $\phi$ and $v$ be given as in (4.1) and (4.2), respectively.

Applying the Korn inequality $(\tilde{K}_\varepsilon)$ to $v$, we find that

$$
||Dv||_{L^p(\Omega)} \leq C_K \left( ||\varepsilon(v)||_{L^p(\Omega)} + ||Dv||_{L^p(Q)} \right),
$$

and can conclude from the construction of $v$ that

$$
|E_B \setminus B(z, 2r)| \leq ||Dv||_{L^p(\Omega)}^p \leq C_K^p \left( ||\varepsilon(v)||_{L^p(\Omega)} + ||Dv||_{L^p(Q)} \right)^p
\leq C_K^p ||\varepsilon(v)||_{L^p(B(z, 2r))}^p \leq 3^n C_K^p |B(z, 2r)|.
$$

Hence, we find that $|E_B \setminus B(z, 2r)| \leq C|B|$. From this and applying Theorem 3.4, we finally obtain that $\Omega$ is a John domain. □

Proof of Theorem 6.2. The implication $(i) \implies (iv)$ is contained in (11) (see Theorem 2.1). The implication $(iv) \implies (i)$ can be seen as follows: if $(iv)$ holds for some $p \in (1, \infty)$, then Lemma 2.2 implies $(K_\varepsilon)$ on $\Omega$, $1/p + 1/q = 1$, and therefore $(i)$ holds by Theorem 4.1.

The implications $(i) \implies (ii), (iii)$ are rather standard and are proved in Corollary 2.3. The implications $(ii), (iii) \implies (i)$ are proved in Theorem 4.1 and Theorem 5.2 respectively.

It is obvious that $(ii'), (iii'), (iv')$ implies $(ii), (iii), (iv)$, respectively. Conversely, if one of conditions $(ii), (iii)$ and $(iv)$ holds, then $(i)$ holds, i.e., $\Omega$ must be John, Theorem 2.1 and Corollary 2.3 imply that $(ii'), (iii'), (iv')$ all hold. □

6 Further discussions

6.1 The separation property

In this subsection, we discuss the separation property and list several known examples of domains satisfying and not satisfying this property.

It follows quite easily from the definitions that every John domain has the separation property. On the other hand, domains with exterior cusps, e.g.,

$$
\Omega_\alpha = \left\{ x = (x_1, \cdots, x_n) : 0 < x_n < 1, 0 < x_1^2 + \cdots + x_{n-1}^2 < x_n^{\alpha} \right\},
$$

with $n \geq 2$ and $\alpha > 1$ or domains of rooms-and-corridors type (cf. [21, Example 4.1]), satisfy the separation property, but are not John domains. Domains with inward cusps such as $B(0, 1) \setminus \{(x, 0, \ldots, 0) : x \geq 0\} \subset \mathbb{R}^n$ is John and thus also satisfies separation condition.
A domain with flat exterior cusp
\[
\Omega'_\alpha = \left\{ x = (x_1, \ldots, x_{n+1}) : 0 < x_n, x_{n+1} < 1, 0 < x_1^2 + \cdots + x_{n-1}^2 < x_n^{2\alpha} \right\} \subset \mathbb{R}^{n+1}
\]
does not satisfy John condition nor separation property.

More generally, one has

**Lemma 6.1** (Buckley-Koskela [6]). Suppose that \( \Omega \subset \mathbb{R}^n \) is quasiconformally equivalent to a uniform domain \( G \subset \mathbb{R}^n, n \geq 2 \). Then \( \Omega \) has the separation property.

Above, by \( \Omega \) quasiconformally equivalent to \( G \), we mean there is a homeomorphism \( f \) of \( G \subset \mathbb{R}^n \) onto \( \Omega \subset \mathbb{R}^n \) with \( f \in W^{1,n}_{\text{loc}}(G, \mathbb{R}^n) \) for which there exists a constant \( K \geq 1 \) such that
\[
|Df(x)|^n \leq K J_f(x) \quad \text{for almost every } x \in G,
\]
here \( J_f \) is the Jacobian determinant of \( Df \). If \( K = 1 \) then the resulting mappings are conformal mappings. Other examples of quasiconformal mappings are bi-Lipschitz mappings in all dimensions.

A domain \( G \) is *uniform* if there is a constant \( C > 0 \) such that for any pair \( x, y \in G \) there exists a curve \( \gamma : [0, \ell] \to G \) parametrised by arclength such that \( \gamma(0) = x, \gamma(\ell) = y, \ell \leq C|x-y| \), and
\[
d(\gamma(t), \mathbb{R}^n \setminus G) \geq \frac{1}{C} \min(t, \ell-t);
\]
see [6, 24] for more about uniform domains. Typical examples of a uniform domains are the balls in \( \mathbb{R}^n \). Therefore, all quasiconformal images of balls have separation property. Notice that a uniform domain is always a John domain, but the converse is not true.

The following result is somehow well known, we include a proof for completeness; see [6].

**Corollary 6.2.** Any finitely connected plane domain satisfies the separation property.

**Proof.** By Koebe’s uniformization theorem, any finitely connected plane domain is conformally equivalent to a circle domain, where a circle domain means each component of its boundary is either a point or a circle; see [18] for instance. The above lemma together with Jones [24, Theorem 4] then gives the desired conclusion. \( \square \)

This corollary together with Theorem 1.5 gives Corollary 1.6 for any finitely connected domains in the plane. On the other hand, Example 1.7 shows analogues of Corollary 1.6 fails for infinitely connected domains in the plane. Notice that an infinitely connected domain might be or be not a John domain. For instance, on the plane, a domain obtained by removing a countable set \( F \) from the unit ball \( B(0, 1) \), where \( F = \bigcup_{k \in \mathbb{N}} \{1 - 2^{-k}, 0\} \), is a John domain, while the domain \( \Omega \) from the following example is not a John domain.

We remark that the domains used in the following two examples are from Buckley-Koskela [6].

**Example 1.7.** Take a ball \( B = B(0, 1) \). For each \( k \in \mathbb{N} \), let \( E_k = \{x_{k,j}\}_{j=1}^{k^l} \), where \( x_{k,j} \) are equally spaced on the circle \( \{x : (0, 1 - 2^{-k}) \subset \mathbb{R}^2 \). Let \( \Omega := B \setminus E \), where \( E = \bigcup_{k \in \mathbb{N}} E_k \). We claim that \( \Omega \) is an infinitely connected plane domain, which supports the Korn inequality, but is not a John domain.

Notice that \( E \) consists of countable points, and hence is removable for Sobolev spaces \( W^{1,p} \); see Koskela [27]. Since \( B = B(0, 1) \) supports the Korn inequality, \( E \) is removable, we see that \( \Omega \) supports the Korn inequality as well. However, \( \Omega \) is not John. To see this, let us argue by contradiction. Suppose that \( \Omega \) is a John domain with a distinguished point \( x_0 \). Then \( \Omega \) is a John domain with the distinguished point as the origin. Take an arbitrary point \( y_k \in \Omega \) with \( |y_k| = 1 - 2^{-k} \).
Then for any curve $\gamma_k$ linked $y_k$ to the origin, there is a point $z_k \in \gamma_k \cap S(0, 1 - 2^{-k+1})$, then $\text{length}(\gamma([y_k, z_k])) \geq 2^{-k}$, while $\rho(z_k) = d(z_k, \mathbb{R}^2 \setminus \Omega) \leq d(z_k, E_k) \leq \frac{C}{k}$. This implies, there cannot exist a constant $C_J > 0$ such that

$$\frac{C}{k} \geq \rho(z_k) \geq C_J \text{length}(\gamma([y_k, z_k])) \geq C_J 2^{-k},$$

since $2^k/k! \to 0$ as $k \to \infty$. Therefore, $\Omega$ is not John, but supports the Korn inequality. 

Regarding higher dimensional cases, one cannot hope for exact analogues of Corollary 1.6 in dimensions $n \geq 3$ as we explained in the introduction; see [24] and [6]. We next complete the construction of Example 1.8.

**Example 1.8** Let $\Delta = B(0, 1) \subset \mathbb{R}^2$, and $E = \bigcup_{k \in \mathbb{N}} E_k$ be as in the previous proof. Let $F = E \times (0, 1)$ and $D = \Delta \times (-1, 1)$. Consider the domain $\Omega := D \setminus F \subset \mathbb{R}^3$. The domain $\Omega$ is then a simply connected domain in $\mathbb{R}^3$. Arguing similar to the previous proof, one can see that $\Omega$ supports the Korn inequality, but $\Omega$ is not a John domain. Similarly, one can construct examples in all dimensions $n \geq 3$. 

Example 1.8 illustrates that the connectivity is not suitable for characterization of Korn inequality in high dimensional cases. The separation property turns out to be a natural requirement in the sense that, it allows us to get an almost complete classification of domains which supports Korn inequality in the plane, and works well also in the higher dimensions.

Using the theory of removable sets for Sobolev functions, one can also show that for the domains in Examples 1.7 and 1.8 ($D E_p$) for the divergence equation holds for $p \in (1, \infty)$. It would be interesting to know if there are domains, without the separation property, such that the Korn inequality holds but ($D E_p$) fails for some $p \in (1, \infty)$.

Notice that, in higher dimensions, there is a rich class of domains satisfying the separation property. Besides John domains and Hölder domains as we recalled before Lemma 6.1, one can use quasiconformal mappings via Lemma 6.1 to construct sufficient many examples; see Gehring-Väisälä [16]. However, there is not a complete classification of domains under (quasi)conformal mappings as in the two dimensional case. Indeed, it is still an important open question whether one can characterize domains that are quasiconformally equivalent to the unit ball in $\mathbb{R}^n$, $n \geq 3$; see Gehring [15].

### 6.2 Further questions

In this subsection, let us discuss some remaining questions related to our results.

There is a different type of Korn inequality

$$\langle \widetilde{K}_{p,w} \rangle \quad \|Dv\|_{L_p(\Omega)} \leq C \left(\|\varepsilon(v)\|_{L_p(\Omega)} + \|v\|_{L_p(\Omega)}\right).$$

Obviously, $(\widetilde{K}_{p,w})$ is weaker than $(\widetilde{K}_p)$. Even on simply connected planar domain, we do not know how to obtain the geometric counterpart of $(\widetilde{K}_{p,w})$. Indeed, as observed in [21], if two disjoint domains support $(\widetilde{K}_{p,w})$, respectively, then their union admits a $(\widetilde{K}_{p,w})$, possibly with larger
constant. However, \((K_p)\) or \((\tilde{K}_p)\) does not have this property. Therefore, in this case it looks hard to derive the same geometric counterpart as from \((K_p)\) or \((\tilde{K}_p)\).

There is also an open problem regarding the relation of the constants in \((K_2)\) and the Babuška-Aziz inequality, which is open even on Lipschitz domains; see [10]. Our result does not give any information on the optimal constant in these inequalities.

Acknowledgment

The authors would like to thank Prof. Pekka Koskela for suggesting this topic and for valuable discussions. R. Jiang was partially supported by National Natural Science Foundation of China (Nos. 11671039 & 11626250). The research of A. Kauranen has been supported by the Academy of Finland via the Centre of Excellence in Analysis and Dynamics Research (project No. 271983)
