Prevalence and risk factors for food allergy in older people: protocol for a systematic review

Inês Laia-Dias,1 Carlos Lozoya-Ibáñez,2 Isabel Skypala,3 Jorge M R Gama,4 Ulugbek Nurmatov,5 Olga Lourenço,1,6 Luis Taborda-Barata6,7

ABSTRACT

Introduction Studies suggest that the prevalence of food allergy may be increasing worldwide. Results regarding the prevalence and features of adverse food reactions older people have, however, scarcely been analysed in the literature. Thus, the objective of the present systematic review will be to describe the prevalence of food allergy in older individuals, its risk factors, clinical features, as well as the most frequently and commonly involved foods.

Methods and analysis We will conduct a systematic review and meta-analysis of the incidence, prevalence and risk factors for food allergy in older individuals. We will search international electronic databases including MEDLINE, EMBASE, Cochrane Library, CINAHL, AMED and ISI Web of Science for published, unpublished and ongoing studies from 1980 to January 2019. There will be no restriction on the language or geography of publication. We will use the critical appraisal skills programme quality assessment tool to appraise the methodological quality of included studies. A descriptive summary with data tables will be elaborated, and if deemed clinically relevant and statistically adequate, meta-analysis using random-effects modelling will be carried out, given the expected clinical, methodological and statistical heterogeneity of studies. The Preferred Reporting Items for Systematic Reviews and Meta-Analyses checklist will guide reporting of the systematic review.

Ethics and dissemination Since this systematic review will be solely based on published and retrievable literature, no ethics approval will be obtained. This study will allow us to draw up-to-date estimates of the prevalence of adverse food reactions in older individuals, worldwide, besides allowing the identification of its major risk factors, clinical manifestations and predominant foods responsible for such reactions. A multidisciplinary team has been assembled for this systematic review and will participate in relevant dissemination activities, namely reports, publications and presentations.

Strengths and limitations of this study

► Food allergy is a growing problem worldwide namely in older individuals.
► This is the first systematic review which will specifically address issues related to food allergy in older people, which may have clinical implications.
► A thorough and highly sensitive search strategy in leading databases, with no geographical or language restrictions, will be conducted by a multidisciplinary team with expertise in the field.
► Study heterogeneity in terms of operational definitions of food allergy may hinder a meta-analysis.

BACKGROUND

The prevalence of food allergies in the general adult population is less well known than in children, since there are fewer studies in the former. Nevertheless, meta-analyses have estimated the prevalence of food allergy in adults to vary between 3.5% and 35% when only based on self-report, and between 2% and 4% when studies include more stringent additional criteria such as positive skin prick tests (SPT) and/or food-specific IgE levels or the gold standard of double-blind placebo-controlled food challenge.1–3

In addition, the prevalence of food allergy may be increasing worldwide, not only in western countries but also in other countries which have adopted a westernised living style.1,4

However, it should be borne in mind that epidemiological studies of food allergies most frequently focus on children and young adults, and reports that specifically include older individuals are scarce.1–3 In fact, most epidemiological results of food allergy involving older people are included in studies that addressed this issue in global populations of adults. Overall, it is not clear whether the prevalence of food allergy is similar, lower or higher in older individuals than in young adults or in children. In this context, a previous meta-analysis has shown that it may be higher in older Europeans,1 although a second, previous meta-analysis, which screened studies from European and non-European countries showed that the prevalence of food allergy was lower in adults than in children2; however, the latter study only used aggregated data, and did not
specifically analyse older adults. Thus, further studies are necessary to clarify this issue. Nevertheless, the prevalence of food allergy may also be increasing in older individuals. For example, the analysis of the US Food and Drug Administration Food Safety Surveys study, which are cross-sectional, telephone surveys of adult American consumers conducted every 3–5 years since 1988 showed that the prevalence of self-reported food allergy increased between 2001 and 2010 in older individuals, although this was only significant in the 60-year-old to 69-year-old group (an increase from 7.7% to 11.7%; p<0.002), but not in the >70-year-old group (increase from 8.7% to 10.6% but p=0.337).6

It should also be taken into account that the numbers and relative percentage of older people are increasing worldwide. According to the United Nations,7 in 2017, 13% of the world population was aged 60 years or over and 2% was aged 80 years or over. In comparison with 2017, by 2050, the population aged 60 years and over is expected to increase twofold (962 million to 2.1 billion), and the population aged 80 years and over may treelfold (137 million to 425 million).

The ageing process is accompanied by immunophysiological and biochemical changes that may make food allergies manifest differently in older people, a situation which may be further compounded by concurrent medications and comorbidities, as well as lack of awareness of the problem.8 8 9 10 These factors may lead to underdiagnosis and undertreatment of food allergies in older individuals.8 8 9 10 Furthermore, these changes might be reflected not only in clinical manifestations of food allergy but also in positivity of skin test results or levels of food-specific IgE antibodies, which may result in differences in detectable prevalence and risk factors, as well as in predominant foods associated with food allergy in older people. All of these points may demand a different approach regarding its diagnosis and management in comparison with younger adults.8 However, to the best of our knowledge, no previous systematic review has been published on epidemiological aspects of food allergies specifically in older individuals.

Thus, the objectives of this systematic review will be: (1) to describe the worldwide prevalence, and time trends of food allergy in older people, (2) to describe clinical manifestations and predominant foods associated with food allergy in older people; (3) to analyse risk and prognostic factors associated with food allergy in older individuals.

METHODS AND ANALYSIS

Search strategy
The summary of this systematic review protocol has been registered in the International Prospective Register of Systematic Reviews (PROSPERO)10.

We have developed a comprehensive search strategy for screening published and unpublished studies. As sources of published studies, we will search the Cochrane Library (Cochrane Database of Systematic Reviews, Cochrane Central Register of Controlled Trials, Cochrane Methodology Register), MEDLINE, EMBASE, CINAHL, AMED and ISI Web of Science (Science and Social Science Index).

The bibliographies of all eligible studies will also be scrutinised to identify additional possible studies. Unpublished and research in progress will be searched in key internet-based relevant databases—www.clinicaltrials.gov; http://www.isrctn.com/ (ISRCTN Registry); www.anzctr.org.au. In addition, to extend our search for published, unpublished and ongoing studies, we will contact an international panel of experts in this field.

Studies from all over the world will be included, if they meet the inclusion/exclusion criteria. No language restrictions will be imposed; translations will be undertaken where necessary. We will report any literature that we are unable to translate. Search dates will be from 1980 until January 2019. Search terms are detailed in online supplementary appendix 1. If any changes are made to the protocol, these will be registered by submission of an updated version to PROSPERO, and will also be documented on the final manuscript with the results of the systematic review.

Inclusion criteria for study designs
We will include all observational, including cohort, case-control and cross-sectional studies. In addition, systematic reviews and meta-analyses with the same focus will be scrutinised. These study designs were selected to ensure the selection and pooling of the highest possible level of evidence based on the aims of this review.

In terms of population, we will select studies that include (not only exclusively) participants aged 60 years or older, reporting or having a diagnosis of food allergy. This cut-off age will used as a criterion for considering an individual as ‘older adult’ since our systematic review will include studies from all over the world, and the WHO proposed 60 years as a working definition of an ‘older person’ in African countries.11 In addition, although 65 years is recommended by WHO as a cut-off level in western countries,12 13 and this is the threshold used in most studies in older individuals in those countries, there are some epidemiological studies also performed in such countries which use 60-year cut-off age for identifying older people.14 Thus, we will include data from all individuals who are 60 years or older, in order to ensure that our study will be fully inclusive.

The following study designs will be excluded: narrative literature reviews, discussion papers, non-research letters and editorials, case studies and case series, animal studies.

Study selection
Titles and abstracts of included papers will be independently checked by two investigators. The full text of all potentially eligible studies will be retrieved and independently assessed against the inclusion criteria (see above) by two reviewers. The reviewers will decide which of the studies fit the inclusion criteria: any disagreements
Heterogeneity

Forest plot and Funnel plot

Laia-Dias I,

food challenges (open, single-blinded, double-blinded).

(based on SPT results, skin prick–prick test results, food

assessment, clinician diagnosis, allergic sensitisation

of food allergies, we will include all methods that were

collected to data. Before using the form, we will test it in

a pilot extraction step with a selected sample of studies.

This will allow us to check the capacity of the constructed

for to capture the relevant information that will be used

for analysis.

If necessary, we will collect indirect data from figures

and charts, adapting their interpretation from two

different authors by consensus, and authors of original

articles will also be contacted for further information

and data. In articles in which data from older patients

were analysed together with those from younger patients,

authors will be contacted in order to clarify or make avail-

able data pertaining to the former group, for subgroup

analyses.

Data items

The following information will be collected from selected

studies involving older individuals, using the same

approach that was previously used in a systematic review

protocol which involved all epidemiological parama-

ters of food allergies in European individuals of various

ages but which did not focus on older individuals14: (1)

frequency of food allergy (i) by self-report; (ii) by clin-

ical symptoms plus positive SPT or IgE to food allergens;

(iii) by clinical symptoms, positive SPT or IgE to food

allergens and also food challenge confirmed; (2) most

frequently involved food allergens; (3) most frequently

observed symptoms and symptom clusters; (4) timeframe

of symptom development on ingestion of foods; (5) time

trends in frequency of food allergy; (6) geographical

differences in prevalence of food allergy and related food

allergens; (7) risk factors for food allergy.

Outcome assessment

Diverse methods of assessment have been used to define

food allergy in different studies. Thus, for estimation of

the prevalence (point, period and lifetime prevalence)

and incidence (incidence rate, cumulative incidence)

of food allergies, we will include all methods that were

used in previous primary studies, including self-reported

assessment, clinician diagnosis, allergic sensitisation

(based on SPT results, skin prick–prick test results, food

allergen-specific IgE levels, skin atopy patch tests) and

food challenges (open, single-blinded, double-blinded).

However, analyses will take into account each such type of

operational definition of food allergy in epidemiological

studies.

Regarding the analysis of risk factors and clinical mani-

festations of adverse food reactions, we will only include

studies that have studied objectively confirmed food

allergic reactions (using food challenges), since this will

ensure the most robust approach to assessing a potential

causal relationship between the studied risk factors and

the studied outcome (food allergy as expressed by food-in-

duced symptoms in a food challenge). This approach was

also followed by the previously mentioned systematic

review by Nwari et al, which studied the epidemiology of

food allergy for all ages, in Europe.3

Risk of bias assessment strategy

Risk of bias assessment will be independently verified by

two different reviewers for each individual study that will

be selected, using the critical appraisal skills programme

quality assessment tool for the types of included studies,

including assessment of internal and external validity.15-17

We will assess heterogeneity, consistency and risk of bias.

Quality of evidence and recommendation for the different

outcomes will be assessed using the GRADE (Grading of

Recommendations Assessment, Development and Evalua-

tion) system.18

All studies and their individual elements will be graded

in terms of adequacy of the study regarding the research

question, risk of selection bias, measurement of expo-

sure and assessment of outcomes. Disagreements will be

resolved by a third reviewer.

Analysis, data synthesis, publication bias and reporting

A narrative synthesis of the data will be performed. In

addition, a descriptive summary with data tables will

be elaborated, in order to summarise literature find-

ings,19 and if deemed clinically relevant and statistically

adequate, meta-analysis using random-effects model-

ling will be carried out.20-22 Forest plot and Funnel plot

charts will be made, if necessary, to compare results or

to identify publication bias, since publication bias leads

to funnel plot asymmetry, if 10 or more relevant studies

are detected.23 Begs and Egger’s methods will be used for

testing such funnel plot asymmetry.24 25 Heterogeneity

between studies will be analysed using the χ² statis-

tical index.26 Subgroup analysis may eventually be carried

out using the following age groups: 60–65, 66–80 and >80

years, if appropriate and if such data can be retrieved

from the literature of after contacting authors. Statistical

analysis will be carried out using SPSS V.25.0. Finally, the

Preferred Reporting Items for Systematic Review and

Meta-Analysis Protocols statement and checklist will be

followed for reporting of the systematic review.27 28

Ethics, dissemination data protection

Ethical approval was not obtained since the data to be

collected and analysed cannot be linked to specific indi-

viduals. A data management plan will be implemented in

will be resolved by discussion, with a third researcher

brought in to arbitrate if needed.

To ensure transparency, the process of selection will

be summarised using a Preferred Reporting Items for

Systematic Reviews and Meta-Analyses flow diagram.

Data extraction

Data from selected articles will be extracted independently

by two reviewers who will transfer data from their origi-

nal presentation to a proper form made in Microsoft

Excel software, with each study receiving a reference

code. Any discrepancy will be resolved by discussion with

the third reviewer. If an article presents results from N

different studies, then, N different forms will be created

to collect data. Before using the form, we will test it in

a pilot extraction step with a selected sample of studies.

This will allow us to check the capacity of the constructed
cases in which data from specific studies can be accessed directly or obtained from article authors. Retrieved data will be kept in a database that will have protected access and will only be used by the involved authors.

**Patient and public involvement**

Since this will be a systematic review, there will be no direct patient or public involvement.

**Ethics and dissemination**

This systematic review, based on studies published between 1980 and January 2019, will allow us to make assessments and estimates considering the appropriateness of the study design regarding the questions, methods used and risk of selection bias.

More specifically, one strength of the review is that it is novel in that we will provide estimates on the following aspects of food allergy with a focus on older individuals: (1) worldwide prevalence of food allergy in this subgroup of adults; (2) geographical differences in prevalence of food allergy and related food allergens; (3) time trends in prevalence of food allergy and related food allergens; (4) predominant foods associated with food allergy; (5) most frequent symptoms/symptom clusters, as well as their severity, associated with food allergy; (6) most frequent symptoms associated with specific foods; (7) timeframe of symptom development on ingestion of foods; (8) need for treatment of episodes of food allergy; (9) risk factors associated with food allergy; (10) quality of life due to food allergy (if enough data are available).

Our results will potentially allow drawing conclusions about general and specific aspects of food allergies in older people. This information may be crucial to analysing similarities and differences regarding food allergies between older and younger individuals and eventually defining preventive or diagnostic approaches specifically tailored to the former age group.

Our dissemination strategy will involve presentation at scientific meetings, as well as publication of article(s) in international, peer-reviewed, open-access journals. However, given the increasing relative percentage of older people in the population, the relative lack of awareness of food allergy in this age group, as well as the inherent difficulties in diagnosing food allergies in older individuals, we also plan to organise meetings with general practitioners and other healthcare providers, to analyse and discuss our findings and their potential implications.

**Acknowledgements**

The authors would like to acknowledge Dr Rosa Saraiva, main librarian at the Cova da Beira University Hospital Centre, and Head of the Research and Innovation Department of this institution, for invaluable input in terms of discussion of this manuscript. In addition, the authors would also like to thank Dr Bright Nwaru, Group Leader at the Institute of Medicine, University of Gothenburg, Sweden, for his precious comments regarding the initial steps of designing the search strategy.

**Contributors**

IL-D and CL-I are equal contributors to the design and conceptualisation of this review, and drafted the protocol with primary support from UN (review guarantor) and LT-B. UN, IS and OL were involved in checking various steps of the search strategy, including keywords, as well as the final version of the protocol. JMRG was involved in the statistical strategy for data analysis. IL-D, CL-I and LT-B were involved in establishing eligibility criteria and data extraction forms. All authors provided feedback on the manuscript, at all stages.

**Funding**

The authors have not declared a specific grant for this research from any funding agency in the public, commercial or not-for-profit sectors.

**Competing interests**

None declared.

**Patient consent for publication**

Not required.

**Provenance and peer review**

Not commissioned; externally peer reviewed.

**Open access**
