Abstract

In this paper, a thermal-dynamical consistent model for mass transfer across permeable moving interfaces is proposed by using energy variation method. We consider a restricted diffusion problem where the flux across the interface depends on its conductance and the difference of the concentration on each side. The diffusive interface phase-field framework used in here has several advantages over the sharp interface method. First of all, explicit tracking of the interface is no longer necessary. Secondly, the interfacial condition can be incorporated with a variable diffusion coefficient. A detailed asymptotic analysis confirms the diffusive interface model converges to the existing sharp interface model as the interface thickness goes to zero. A decoupled energy stable numerical scheme is developed to solve this system efficiently. Numerical simulations first illustrate the consistency of theoretical results on the sharp interface limit. Then a convergence study and energy decay test are conducted to ensure the efficiency and stability of the numerical scheme. To illustrate the effectiveness of our phase-field approach, several examples are provided, including a study of a two-phase mass transfer problem where drops with deformable interfaces are suspended in a moving fluid.

1 Introduction

Mass transfer through a semi-permeable or conducting interface is a common phenomenon in biology [12, 9] and material science [8, 13]. A representative example is that cell membranes are permeable to oxygen [26], ATP [33] and ions [17]. In this case, the domain consists of intracellular space denoted by $\Omega^+$ and extracellular space denoted by $\Omega^-$ with a cell membrane $\Gamma$ in between (see Figure 1). The diffusion of concentration can be described by the following diffusion equation in the bulk [30],

$$\frac{\partial c^\pm}{\partial t} + \nabla \cdot (u^\pm c^\pm) = \nabla \cdot (D^\pm \nabla c^\pm),$$

(1.1)

Figure 1: Schematic of mass transport across the membrane.
where \( c^\pm, \mathbf{u}^\pm \) represent the concentration of the molecule and velocity of fluid in \( \Omega^\pm \) and \( D^\pm \) is the diffusion coefficient in \( \Omega^\pm \). Here \( c^\pm \) may be discontinuous cross the boundary, like the ion concentrations in [23]. At the interface \( \Gamma \), the trans-membrane flux is set to be continuous
\[
-D^+ \nabla c^+ \cdot \mathbf{n} = -D^- \nabla c^- \cdot \mathbf{n} = K \left[ Q(c) \right],
\]
where \( K \) is the permeability, \([f] = f^+ - f^-\) denotes the jump of concentration across the interface and \( \mathbf{n} \) is the unit normal vector of the interface. Here \( Q(c) \) could have different formats, like \( Q(c) = c \) in [9] or \( Q(c) = \ln c \) in [30].

There are numerous papers investigating for mass transfer. As a matter of fact, the mass transfer phenomenon can be attributed to diffusive process in binary flows involving free boundaries. For the standard fluid-structure interaction problems, a variety of methods are developed over the past decades. There are two most popular classes of technique, the sharp interface methods, like level set methods [1], immerse boundary methods [18], immerse interface methods [15], front tracking methods [24], and diffuse interface methods [32]. For mass-transfer across liquid–gas interface, volume of fluid methods are proposed to solve the phase change problem [27, 6] and bubble behaviours with CO\(_2\)/N\(_2\)–water system [16]. The immersed interface method is extended to study water transport across a deformable membrane by Layton [14].

The immerse boundary method, due to its simplicity, has been applied to many fluid flow problems and has become one of the main numerical techniques for scientifiic computation. Gong and Huang et al. [9, 26] developed a series of work to understand oxygen transport across permeable membrane by using immerse interface method. In order to ensure the restrict diffusion on the membrane (1.2), an additional equation is introduced to describe the temporal evolution of diffusive flux.

Unlike sharp interface methods, where the interface are handled separately by using \( \delta \) function or local reconstruction, the diffusive interface method models the two phase flow and the interface in a uniform way by a label function \( \phi \) [3, 2, 4]. The basic idea can be dated back to van der Waals in the late 19th century [25]. The main advantage of diffusive interface method is that follows the energy dissipation law such that the obtained model is thermal-dynamical consistent. It makes it possible to design efficient energy stable schemes for long time simulation. However, to our best knowledge, there is not a diffusive interface model for mass transport through a semi-permeable membrane. The main challenge is how to impose the restricted diffusion near interface such that as interface thickness goes to zero, the sharp interface limit is consistent with boundary condition (1.2).

In this paper, a thermal-dynamical consistent diffusive model is first proposed by using energy variational method [22], which starts from two functionals for the total energy and dissipation, together with the kinematic equations based on physical laws of conservation. The key is to modify the diffusion coefficient as a function of \( \phi \) and interface permeability \( K \). The restricted diffusion only means that the changing rate of energy near the interface follows a specific dissipation rate functional. Then following the results of Xu et al. [31], a detailed asymptotic analysis is presented to confirm the proposed diffusive interface model converges to the existing sharp interface model (1.1) and (1.2) as the interface thickness goes to zero. In the next, based on the energy dissipation law, an efficient energy stable decoupled scheme is proposed to solve the obtained system.

The structure of the paper is as follows. In section 2, the phase field model for mass transport through a semi-permeable interface is proposed by using energy variational method. In section 3, the sharp interface limits of the phase field model are presented by asymptotic analysis. A decoupled, linear and unconditional energy stable numerical scheme is developed in section 4 by means of the stabilization method and pressure correction method. In section 5, numerical experiments are carried out to verify our theoretically results and study the membrane permeability effect. Finally, conclusions are drawn in section 6.

## 2 Phase field model for mass transfer with hydrodynamics

In this section, energy variation method is used to derive a diffusive interface model for mass transport through a semi-permeable membrane with restrict diffusion.

### 2.1 Model derivation

First, phase field variable \( \phi \) is introduced to label the different domain,

\[
\phi(x, t) = \begin{cases} 
1, & \text{in } \Omega^+, \\
-1, & \text{in } \Omega^-.
\end{cases}
\]
The interface between the two domains is described by the zero level set \( \Gamma_t = \{ x : \phi(x, t) = 0 \} \). We will omit the subscript \( t \) in the following, i.e. we use \( \Gamma \) to instead \( \Gamma_t \).

We start from the following kinematic assumptions on the laws of conservation: in domain \( \Omega \)

\[
\begin{align*}
\frac{D\phi}{Dt} &= -\nabla \cdot j_\phi, \\
\frac{Dc}{Dt} &= -\nabla \cdot j_c, \\
\rho \frac{D\nabla c}{Dt} &= \nabla \cdot \sigma_\nu + \nabla \cdot \sigma_\phi, \\
\nabla \cdot u &= 0,
\end{align*}
\tag{2.2a}
\tag{2.2b}
\tag{2.2c}
\tag{2.2d}
\]

where \( \rho \) is the density, \( \phi \) is the phase label function, \( c \) is the concentration of a substance, \( u \) is the fluid velocity, and \( \frac{Df}{Dt} = \frac{df}{dt} + (u \cdot \nabla) f \) is the material derivative.

Here Eq. (2.2a) is the conservation of label function with unknown flux \( j_\phi \); Eq. (2.2b) is the conservation of mass with unknown mass flux \( j_c \); Eq. (2.2c) is the conservation of momentum with unknown stress induced by viscosity of fluid \( \sigma_\nu \) and stress induced by two-phase flow interface \( \sigma_\phi \).

On the boundary of the domain, the boundary conditions can be given as

\[
\begin{align*}
\overline{j_\phi} \cdot n|_{\partial \Omega} &= 0, \\
\overline{j_c} \cdot n|_{\partial \Omega} &= 0, \\
\nabla \phi \cdot n|_{\partial \Omega} &= 0, \\
u|_{\partial \Omega} &= 0,
\end{align*}
\tag{2.3}
\]

where \( n \) is the outward normal on the domain boundary \( \partial \Omega \). Then the system (2.2) conserves the local mass density, i.e. \( \frac{d}{dt} \int_\Omega c \, dx = 0 \) and \( \frac{d}{dt} \int_\Omega \phi \, dx = 0 \).

The total energy consists of kinetic energy, mix entropy and the phase mixing energy

\[
E_{\text{total}} = E_{\text{kin}} + E_{\text{ent}} + E_{\text{mix}} = \frac{1}{2} \int_\Omega \rho |u|^2 \, dx + \int_\Omega RTc \left( \ln \frac{c}{c_0} - 1 \right) \, dx + \int_\Omega \lambda G(\phi) + \frac{\gamma^2}{2} \left| \nabla \phi \right|^2 \, dx,
\tag{2.4}
\]

where \( G(\phi) = \frac{1}{2} (1 - \phi^2)^2 \) is the double well potential. \( R \) is the gas constant number, \( T \) is the thermodynamic temperature, \( c_0 \) is the reference concentration, \( \lambda \) is the energy density, \( \gamma \) is the thickness of the interface.

Then according to the total energy, we could define the chemical potentials

\[
\begin{align*}
\mu_c &= \frac{\delta E}{\delta c} = RT \ln \frac{c}{c_0}, \\
\mu_\phi &= \frac{\delta E}{\delta \phi} = -\gamma^2 \Delta \phi + \lambda G'(\phi).
\end{align*}
\tag{2.5}
\tag{2.6}
\]

The dissipative functional is composed of the dissipation due to fluid friction, irreversible mixing of the substance and irreversible mixing of two phases in bulk

\[
\Delta = \int_\Omega \frac{2\nu(\phi)}{RT} |D_\nu|^2 \, dx + \int_\Omega \frac{D_{\text{eff}}c}{RT} |\nabla \mu_c|^2 \, dx + \int_\Omega M |\nabla \mu_\phi|^2 \, dx,
\tag{2.7}
\]

where \( \nu(\phi) \) is the viscosity for the fluid, \( D_\nu = \frac{\nabla u + (\nabla u)^T}{2} \) is the strain rate, \( M \) is the phenomenological mobility.

In order to model the restricted diffusion due to the permeability of the interface, the diffusion coefficient \( D_{\text{eff}} \) is modelled in the following way

\[
\frac{1}{D_{\text{eff}}} = \frac{(1 - \phi^2)^2}{ARq^2} + \frac{1 - \phi}{2D_-} + \frac{1 + \phi}{2D_+},
\tag{2.8}
\]

where \( K \) is the permeability for the membrane, \( A \) is a constant to be determined, \( q = \frac{dQ}{dx} \) and \( D_+ \) and \( D_- \) are the diffusion coefficients in domain \( \Omega^+ \) and \( \Omega^- \) respectively.

The energy dissipative law [7, 30, 22] states that without external force acting on the system, the changing rate of total energy equals the dissipation

\[
\frac{d}{dt} E_{\text{total}} = -\Delta.
\tag{2.9}
\]
Then the definition of total energy functional (2.4) yields
\[
\frac{dE_{\text{tot}}}{dt} = \frac{dE_{\text{cont}}}{dt} + \frac{dE_{\text{kin}}}{dt} + \frac{dE_{\text{mix}}}{dt} = I_1 + I_2 + I_3. \tag{2.10}
\]
By using the definitions of chemical potential (2.5) and conservation law (2.2b), the first part yields
\[
I_1 = \int_{\Omega} \mu_c (\frac{\partial c}{\partial t} + u \cdot \nabla c) dx
= - \int_{\Omega} \mu_c \nabla \cdot j_c dx
= - \int_{\partial \Omega} \mu_c \phi_n dx + \int_{\Omega} \nabla \mu_c \cdot j_c dx
= \int_{\Omega} \nabla \mu_c \cdot j_c dx. \tag{2.11}
\]
where the nonflux boundary condition for \( j_c \) is used here.
For the second term, by using Eqs.(2.2c) and (2.2d), we have
\[
\frac{d}{dt} E_{\text{kin}} = \frac{d}{dt} \left( \frac{1}{2} \int_{\Omega} \rho |u|^2 dx \right)
= \frac{1}{2} \int_{\Omega} \left( \frac{\partial \rho}{\partial t} u^2 + \int_{\Omega} \rho u \cdot \frac{\partial u}{\partial t} dx \right)
= \frac{1}{2} \int_{\Omega} \left( \frac{\partial \rho}{\partial t} u^2 + \int_{\Omega} \rho u \cdot \frac{Du}{Dt} dx + \int_{\Omega} \nabla \cdot (\rho u) |u|^2 dx \right)
= \int_{\Omega} u \cdot (\nabla \cdot \sigma_n + \nabla \cdot \sigma_\phi) dx - \int_{\Omega} p \nabla \cdot u dx
= - \int_{\Omega} \nabla u : (\sigma_n + \sigma_\phi) dx - \int_{\Omega} p \nabla \cdot u dx. \tag{2.12}
\]
where pressure is induced as a Lagrange multiplier for incompressibility.

The last term is calculated with Eqs.(2.2a) and (2.6)
\[
\frac{d}{dt} E_{\text{mix}} = \frac{d}{dt} \int_{\Omega} (G(\phi) + \frac{\gamma^2}{2} |\nabla \phi|^2) dx
= \int_{\Omega} \left( G'(\phi) \frac{\partial \phi}{\partial t} + \gamma^2 \nabla \phi \cdot \nabla \phi \right) dx
= \int_{\Omega} G'(\phi) \frac{\partial \phi}{\partial t} dx + \int_{\Omega} \gamma^2 \frac{\partial \phi}{\partial \phi} \frac{\partial \phi}{\partial t} ds - \int_{\Omega} \nabla \cdot (\gamma^2 \nabla \phi) \frac{\partial \phi}{\partial t} dx
= \int_{\Omega} \left( G'(\phi) - \nabla \cdot (\gamma^2 \nabla \phi) \right) \frac{\partial \phi}{\partial t} dx
= \int_{\Omega} \mu \phi \frac{\partial \phi}{\partial t} + u \cdot \nabla \phi dx - \int_{\Omega} \mu \phi u \cdot \nabla \phi dx
= - \int_{\Omega} \mu \phi \nabla \cdot j_\phi dx - \int_{\Omega} \mu \phi u \cdot \nabla \phi dx
= \int_{\Omega} \nabla \mu \phi \cdot j_\phi dx - \int_{\Omega} \mu \phi \phi_n dx - \int_{\Omega} (G(\phi) - \nabla \cdot (\gamma^2 \nabla \phi)) u \cdot \nabla \phi dx
= \int_{\Omega} \nabla \mu \phi \cdot j_\phi dx - \int_{\Omega} \nabla \mu \phi \cdot j_\phi ds - \int_{\Omega} (G(\phi) - \nabla \cdot (\gamma^2 \nabla \phi)) u \cdot \nabla \phi dx
= \int_{\Omega} \nabla \mu \phi \cdot j_\phi dx - \int_{\Omega} u \cdot \nabla G(\phi) dx + \int_{\Omega} \gamma^2 \Delta \phi \nabla \phi \cdot u dx
= \int_{\Omega} \nabla \mu \phi \cdot j_\phi dx - \int_{\Omega} u \cdot \nabla G(\phi) dx + \int_{\Omega} \gamma^2 (\nabla \cdot (\nabla \phi \otimes \nabla \phi) - \frac{1}{2} \nabla |\nabla \phi|^2) \cdot u dx
= \int_{\Omega} \nabla \mu \phi \cdot j_\phi dx - \int_{\Omega} u \cdot \nabla G(\phi) dx + \int_{\Omega} \gamma^2 \nabla \cdot (\nabla \phi \otimes \nabla \phi) \cdot u dx
= \int_{\Omega} \nabla \mu \phi \cdot j_\phi dx - \int_{\Omega} \nabla \cdot (u(G(\phi) + \frac{\gamma^2}{2} |\nabla \phi|^2)) dx + \int_{\Omega} (G(\phi) + \frac{\gamma^2}{2} |\nabla \phi|^2) \nabla \cdot u dx
\]
\[
\begin{align*}
+ \int_{\Omega} \gamma^2 \nabla \cdot (\nabla \phi \otimes \nabla) \cdot \mathbf{u} \, d\mathbf{x} \\
= \int_{\Omega} \nabla \mu \cdot j_\phi \, d\mathbf{x} - \int_{\Omega} \mathbf{G}(\phi) \cdot u \cdot n \, ds + \int_{\Omega} \gamma^2 \nabla \cdot (\nabla \phi \otimes \nabla) \cdot \mathbf{u} \, d\mathbf{x} \\
= \int_{\Omega} \nabla \mu \cdot j_\phi \, d\mathbf{x} - \int_{\Omega} \gamma^2 (\nabla \phi \otimes \nabla \phi) : \nabla \mathbf{u} \, d\mathbf{x},
\end{align*}
\] (2.13)
where the nonflux boundary of \( j_\phi \) is used.

Then substituting above three equations to Eq. (2.10) yields
\[
\frac{d}{dt} E_{total} = \frac{d}{dt} E_{cnt} + \frac{d}{dt} E_{kin} + \frac{d}{dt} E_{mix}
= \int_{\Omega} \nabla \mu \cdot j_\phi \, d\mathbf{x} - \int_{\Omega} \nabla \mathbf{u} : (\sigma_\nu + \sigma_\phi) \, d\mathbf{x} + \int_{\Omega} \nabla \mu \cdot j_\phi \, d\mathbf{x} - \int_{\Omega} \gamma^2 (\nabla \phi \otimes \nabla \phi) : \nabla \mathbf{u} \, d\mathbf{x}
= - \int_{\Omega} \frac{D_{eff} \mathbf{c}}{RT} |\nabla \mu| \mathbf{u} \, d\mathbf{x} - \int_{\Omega} M |\nabla \mu \phi| \mathbf{u} \, d\mathbf{x} - \int_{\Omega} 2 \nu D_\nu |\nabla \phi| \mathbf{u} \, d\mathbf{x}.
\] (2.14)

Comparing two sides of the above equation (2.14) and calculating the functional derivative, we obtain
\[
\begin{align*}
j_\phi &= -\mathbf{M} \nabla \mu, \quad (2.15a) \\
j_c &= -\frac{D_{eff} \mathbf{c}}{RT} \nabla \mu, \quad (2.15b) \\
\sigma_\nu &= 2 \nu D_\nu - p I, \quad (2.15c) \\
\sigma_\phi &= -\lambda \gamma^2 (\nabla \phi \otimes \nabla \phi). \quad (2.15d)
\end{align*}
\]

Then the diffusive interface model for mass transport through semi-permeable membrane with restricted diffusion is summarized as follows
\[
\begin{align*}
\frac{D\phi}{Dt} &= -\nabla \cdot \mathbf{M} \nabla \mu, \quad (2.16a) \\
\frac{Dc}{Dt} &= -\nabla \cdot \mathbf{j}, \quad (2.16b) \\
\frac{p\mathbf{u}}{Dt} &= \nabla \cdot (\nu \nabla \mathbf{u}) - \nabla p - \lambda \gamma^2 \nabla \cdot (\nabla \phi \otimes \nabla \phi), \quad (2.16c) \\
\nabla \cdot \mathbf{u} &= 0, \quad (2.16d) \\
\mu &= -\lambda \gamma^2 \phi + \lambda G'(\phi), \quad (2.16e) \\
\mathbf{j} &= -D_{eff} \nabla \mathbf{c}, \quad (2.16f) \\
D_{eff}^{-1} &= \left(1 - \phi^2\right)^2 \frac{2 \nu}{AK q_\gamma} + \frac{1 - \phi}{2D_-} + \frac{1 + \phi}{2D_+}, \quad (2.16g)
\end{align*}
\]
with boundary conditions
\[
\nabla \phi \cdot \mathbf{n}|_{\partial \Omega} = 0, \quad \nabla c \cdot \mathbf{n}|_{\partial \Omega} = 0, \quad \nabla \mu \cdot \mathbf{n}|_{\partial \Omega} = 0, \quad \mathbf{u}|_{\partial \Omega} = 0.
\] (2.17)

2.2 Non-dimensionalization

Now we introduce the dimensionless variables
\[
\begin{align*}
\tilde{x} &= \frac{x}{L}, \quad \tilde{u} = \frac{u}{U}, \quad \tilde{t} = \frac{t}{T}, \quad \tilde{\phi} = \frac{\phi}{c_0}, \quad \tilde{K} = \frac{K L}{D_0}, \quad \tilde{D} = \frac{D}{D_0}, \quad T = \frac{L}{U}.
\end{align*}
\] (2.18)

Here \( L, T, c_0, U D_0 \) are the characteristic length, time, concentration velocity and diffusion constant. For convenience, the tilde symbol will be removed in the dimensionless quantities, and the dimensionless system of (2.16) is given by
\[
\begin{align*}
\text{Re} \left( \frac{\partial \mathbf{u}}{\partial \tilde{t}} + (\mathbf{u} \cdot \nabla) \mathbf{u} \right) + \nabla p &= \nabla^2 \mathbf{u} + \frac{1}{\text{Ca}} \mu \nabla \phi, \quad (2.19a) \\
\nabla \cdot \mathbf{u} &= 0, \quad (2.19b)
\end{align*}
\]
\[
\frac{\partial \phi}{\partial t} + (u \cdot \nabla) \phi = \nabla \cdot (M \nabla \mu), \quad (2.19c)
\]
\[
\mu = -\epsilon \nabla^2 \phi + \frac{1}{\epsilon} \phi (\phi^2 - 1), \quad (2.19d)
\]
\[
\frac{\partial c}{\partial t} + (u \cdot \nabla) c = - \frac{1}{Pe} \nabla \cdot j, \quad (2.19e)
\]
\[
j = -D_{\text{eff}} \nabla c, \quad (2.19f)
\]
\[
D_{\text{eff}}^{-1} = \frac{(1 - \phi^2)^2}{AKq\epsilon} + \frac{1}{2D^+} + \frac{1}{2D^-}, \quad (2.19g)
\]

with the boundary condition
\[
u |_{\partial \Omega} = 0, \quad \nabla \phi \cdot n |_{\partial \Omega} = 0, \quad \nabla \mu \cdot n |_{\partial \Omega} = 0, \quad \nabla c \cdot n |_{\partial \Omega} = 0. \quad (2.20)
\]

with the dimensionless parameters
\[
Re = \frac{\rho UL}{\nu}, \quad Ca = \frac{\nu U}{\lambda \gamma}, \quad Pe = \frac{UL}{D_0}. \quad (2.21)
\]

**Remark 2.1.** During the dimensionless, we use the fact that
\[
\nabla \cdot (\nabla \phi \otimes \nabla \phi) = \nabla^2 \phi \nabla \phi + \frac{1}{2} \nabla |\nabla \phi|^2
\]
\[
= -\mu \nabla \phi + \frac{1}{2} \nabla \left( |\nabla \phi|^2 + \frac{1}{\epsilon} G(\phi) \right),
\]

and redefine pressure function
\[
p = p + \epsilon \frac{1}{2C_a} |\nabla \phi|^2 + \frac{1}{2C_a} G(\phi).
\]

**Theorem 2.1.** If \( \phi, c, u \) and \( p \) are smooth solutions of the system (2.19) with boundary condition (2.20), then the following energy law is satisfied:
\[
\frac{d}{dt} \mathcal{E}_{\text{total}} = - \int_{\Omega} (|\nabla u|^2 + \frac{M}{C\mu} |\nabla \mu|^2 + D_{\text{eff}} c |\nabla c|^2) dx, \quad (2.22)
\]

where
\[
\mathcal{E}_{\text{total}} = \int_{\Omega} \left( \frac{Re}{2} |u|^2 + \frac{1}{C_a} \left( \frac{\epsilon}{2} |\nabla \phi|^2 + \frac{1}{4\epsilon} (1 - \phi^2)^2 \right) + c \ln c \right) dx. \quad (2.23)
\]

**Proof.** By taking the \( L^2 \) inner product of (2.19a), (2.19c), (2.19d), (2.19e) and (2.19f) with \( u, \mu, \frac{\partial \phi}{\partial t}, \mu_c \) and \( \frac{\partial c}{\partial t} \) respectively, one obtains immediately (2.22). \( \square \)

## 3 Sharp interface limit

In this section, a detailed asymptotic analysis is presented by using the results in [31] to show the sharp interface limits of the obtained system (2.19). Here we assume the viscosity is constant and \( M = \alpha \epsilon \), where \( \alpha \) is a constant independent of \( \epsilon \).

### 3.1 Outer expansions

Far from the two-phase interface \( \Gamma \), we use the following ansatz:
\[
u^\pm = \nu^0 \pm \epsilon \nu^1 + \epsilon^2 \nu^2 + o(\epsilon^2), \quad (3.1a)
\]
\[
p^\pm = p^0 \pm \epsilon p^1 + \epsilon^2 p^2 + o(\epsilon^2), \quad (3.1b)
\]
\[
\phi^\pm = \phi^0 \pm \epsilon \phi^1 + \epsilon^2 \phi^2 + o(\epsilon^2), \quad (3.1c)
\]
\[
\mu^\pm = \mu^0 \pm \epsilon \mu^1 + \epsilon^2 \mu^2 + o(\epsilon). \quad (3.1d)
\]
\[
c^\pm = c^0 \pm \epsilon c^1 + \epsilon^2 c^2 + o(\epsilon^2), \quad (3.1e)
\]
After defining a new rescaled variable $d$, we first introduce the signed distance function $\phi$ for any scalar function $f$, we assume that

\[
\phi_0^\pm = (C_0^\pm)^3 - C_0^\pm, \quad (C_0^\pm)^3 - C_0^\pm,
\]

\[
\mu_0^\pm = (C_0^\pm)^3 - C_0^\pm, \quad (C_0^\pm)^3 - C_0^\pm,
\]

\[
\nabla \cdot \mathbf{u}_0^\pm = 0, \quad (C_0^\pm)^3 - C_0^\pm,
\]

\[
Re\left(\frac{\partial \mathbf{u}_0^\pm}{\partial t} + (\mathbf{u}_0^\pm \cdot \nabla) \mathbf{u}_0^\pm\right) + \nabla p_0^\pm = \nabla^2 \mathbf{u}_0^\pm + \frac{1}{Ca} \mu_0^\pm \nabla \phi_0^\pm. \quad (3.2d)
\]

Substituting (3.1e),(3.1f) into Eq. (2.19e) yields we have

\[
[2D^+D^-(1 - (\phi_0^\pm + \epsilon \phi_1^\pm + \epsilon^2 \phi_2^\pm + o(\epsilon^2))^2) + A Kq(D^+ + D^-)
+ AKqe(D^- - D^+)(\phi_0^\pm + \epsilon \phi_1^\pm + \epsilon^2 \phi_2^\pm + o(\epsilon^2))](\mathbf{j}_0^\pm + \epsilon \mathbf{j}_1^\pm + \epsilon^2 \mathbf{j}_2^\pm + o(\epsilon^2))
= -2AK\epsilon D^+D^- [q(c_0^\pm) + \epsilon q'(c_0^\pm) c_1^\pm + \epsilon^2 \left(\frac{1}{2} q''(c_0^\pm)(c_1^\pm)^2 + q'(c_0^\pm)c_2^\pm\right) + o(\epsilon^2)](\nabla (c_0^\pm + \epsilon c_1^\pm + \epsilon^2 c_2^\pm + o(\epsilon^2)),
\]

The leading order term of the above equation is

\[
(1 - (\phi_0^\pm)^2)^2 \mathbf{j}_0^\pm = 0, \quad (3.4)
\]

and the next order term is

\[
AKq(c_0^\pm)[(D^+ + D^-) + (D^- - D^+)(\phi_0^\pm + \epsilon \phi_1^\pm + \epsilon^2 \phi_2^\pm + o(\epsilon^2))][\mathbf{j}_0^\pm + \epsilon \mathbf{j}_1^\pm + \epsilon^2 \mathbf{j}_2^\pm + o(\epsilon^2)] = -2AKD^+D^- q(c_0^\pm) \nabla c_0^\pm. \quad (3.5)
\]

The leading order of (2.19e) gives us that

\[
\frac{\partial c_0^\pm}{\partial t} + \mathbf{u}_0^\pm \cdot \nabla c_0^\pm = -\frac{1}{Pe} \nabla \cdot \mathbf{j}_0^\pm. \quad (3.6)
\]

### 3.2 Inner expansions

We first introduce the signed distance function $d(x)$ to the interface $\Gamma$. Immediately, we have $\nabla d = \mathbf{n}$. After defining a new rescaled variable

\[
\xi = \frac{d(x)}{\epsilon}, \quad 7
\]

for any scalar function $f(x)$, we can rewrite it as

\[
f(x) = \tilde{f}(x, \xi),
\]

and the relevant operators are

\[
\nabla f(x) = \nabla_x \tilde{f} + \epsilon^{-1} \partial_x \tilde{f} \mathbf{n},
\]

\[
\nabla^2 f(x) = \nabla_x^2 \tilde{f} + \epsilon^{-1} \partial_x \tilde{f} K + 2\epsilon^{-1} (\mathbf{n} \cdot \nabla_x) \partial_x \tilde{f} + \epsilon^{-2} \partial_x^2 \tilde{f},
\]

\[
\partial_x f = \partial_t \tilde{f} + \epsilon^{-1} \partial_x \tilde{f} \mathbf{n},
\]

and for a vector function $\mathbf{g}(x)$, we have

\[
\nabla \cdot \mathbf{g}(x) = \nabla_x \cdot \mathbf{g} + \epsilon^{-1} \partial_x \mathbf{g} \cdot \mathbf{n},
\]

Here the $\nabla_x$ and $\nabla_x^2$ stand for the gradient and Laplace with respect to $x$, respectively. And we use the fact that $\nabla_x \cdot \mathbf{n} = \kappa$. $\kappa(x)$ for $x \in \Gamma(t)$ is the mean curvature of the interface. In the inner region, we assume that

\[
\tilde{u}_c = \tilde{u}_0 + \epsilon \tilde{u}_1 + \epsilon^2 \tilde{u}_2 + o(\epsilon^2), \quad (3.11a)
\]

\[
\tilde{\phi}_c = \tilde{\phi}_0 + \epsilon \tilde{\phi}_1 + \epsilon^2 \tilde{\phi}_2 + o(\epsilon^2), \quad (3.11b)
\]

\[
\tilde{p}_c = \tilde{p}_0 + \epsilon \tilde{p}_1 + \epsilon^2 \tilde{p}_2 + o(\epsilon^2), \quad (3.11c)
\]

\[
\tilde{c}_c = \tilde{c}_0 + \epsilon \tilde{c}_1 + \epsilon^2 \tilde{c}_2 + o(\epsilon^2), \quad (3.11d)
\]
\[ \tilde{j}_\epsilon = \tilde{j}_0 + \epsilon \tilde{j}_1 + \epsilon^2 \tilde{j}_2 + o(\epsilon^2), \quad (3.11e) \]

And we have

\[ q(\tilde{c}_n^\pm) = q(\tilde{c}_0^\pm) + \epsilon q'(\tilde{c}_0^\pm)\tilde{c}_n^\pm + \epsilon^2 \left( \frac{1}{2} q''(\tilde{c}_0^\pm)(\tilde{c}_n^\pm)^2 + q'(\tilde{c}_0^\pm)\tilde{c}_n^\pm \right) + o(\epsilon^2). \quad (3.12) \]

Then the results in [31] show that

\[ \tilde{\phi}_0 = \tanh \frac{\xi}{\sqrt{2}}. \quad (3.13) \]

By the matching condition \( \lim_{\xi \to \pm \infty} \tilde{\phi}_0 = \phi_0^\pm \), we have

\[ \phi_0^\pm = \pm 1, \text{ in } \Omega^\pm. \quad (3.14) \]

This will lead to \( \rho_0^\pm = 0 \). Therefore the equation (3.2d) is reduced to

\[ \Re \left( \frac{\partial u_0^\pm}{\partial t} + (u_0^\pm \cdot \nabla)u_0^\pm \right) + \nabla p_0^\pm = \nabla^2 u_0^\pm. \quad (3.15) \]

Also, thanks to Eq. (3.14), Eq. (3.5) yields

\[ j_0^\pm = -D^\pm \nabla c_0^\pm. \quad (3.16) \]

with interface conditions

\[ \partial_\xi d + u_0 \cdot n = 0 \quad (3.17a) \]

\[ V_n = u_0 \cdot n, \quad (3.17b) \]

\[ \left[ u_0 \right] = 0, \quad (3.17c) \]

\[ [-p_0 n + (n \cdot \nabla)u_0] = \frac{1}{Ca} \sigma \kappa n, \quad (3.17d) \]

where \( V_n \) is the normal velocity of the interface \( \Gamma \), \( \sigma = \int_{-\infty}^{\infty} (\partial_\xi \tilde{\phi}_0) dx = \frac{2\sqrt{2}}{3} \) is the surface tension.

The concentration function can be transformed into the following form:

\[ \partial_\xi \tilde{c}_\epsilon + \epsilon^{-1} \partial_\xi \tilde{c}_\epsilon \partial_\xi d + \tilde{u}_\epsilon \cdot (\nabla_\xi \tilde{c}_\epsilon + \epsilon^{-1} n \partial_\xi \tilde{c}_\epsilon) = -\frac{1}{Pe} (\nabla_\xi \cdot \tilde{j}_\epsilon + \epsilon^{-1} \partial_\xi \tilde{j}_\epsilon \cdot n), \quad (3.18a) \]

\[ \tilde{j}_\epsilon = -\frac{2AK\epsilon D^+ D^- q(\tilde{c}_\epsilon)}{2D^+ D^- (1 - \phi_0^2) + AKq(D^+ + D^-) + AKq(D^- - D^+)} (\nabla_\xi \tilde{c}_\epsilon + \epsilon^{-1} \partial_\xi \tilde{c}_\epsilon n). \quad (3.18b) \]

The leading order term of equation (3.18a) is

\[ \partial_\xi \tilde{c}_0 \partial_\xi d + \tilde{u}_0 \cdot n \partial_\xi \tilde{c}_0 = -\frac{1}{Pe} \partial_\xi \tilde{j}_0 \cdot n, \quad (3.19) \]

with the application of equation (3.17a), we have

\[ -\partial_\xi \tilde{j}_0 \cdot n = 0 \quad (3.20) \]

which means \( \tilde{j}_0 \cdot n = \text{const.} \)

Integrating the equation (3.20) in \((-\infty, \infty)\) we have

\[ [\tilde{j}_0 \cdot n] = -\int_{-\infty}^{\infty} \partial_\xi \tilde{j}_0 d\xi \cdot n = 0. \quad (3.21) \]

So the flux of concentration is continuous across the interface.

For the equation (3.18b), we have

\[ (2D^+ D^- (1 - \phi_0^2)^2 + AKq(D^+ + D^-) + AKq(D^- - D^+)) \tilde{j}_\epsilon = -2D^+ D^- AKq(\tilde{c}_\epsilon) (\nabla_\xi \tilde{c}_\epsilon + \epsilon^{-1} \partial_\xi \tilde{c}_\epsilon). \]

and the leading order term gives us that

\[ (1 - \phi_0^2)^2 \tilde{j}_0 \cdot n = -AKq(\tilde{c}_0) \partial_\xi \tilde{c}_0. \quad (3.22) \]
Integrating this equation in \((-\infty, \infty)\) we have

\[
AK[Q(c_0)] = AK \int_{-\infty}^{+\infty} q(c_0)d\xi d\xi
= \int_{-\infty}^{+\infty} (1 - \xi^2)^2 j_0 \cdot n d\xi
= j_0 \cdot n \int_{-\infty}^{+\infty} (1 - \tanh^2 \frac{\xi}{\sqrt{2}})^2 d\xi.
\] (3.23)

By defining

\[
A = \int_{-\infty}^{+\infty} (1 - \tanh^2 \frac{\xi}{\sqrt{2}})^2 d\xi = \frac{4\sqrt{2}}{3} = 2\sigma.
\] (3.24)

we obtain

\[
j_0 \cdot n = K[Q(c_0)].
\] (3.25)

Combining the above analysis, at the leading order, we obtain the following results:

\[
Re \left( \frac{\partial u_0^\pm}{\partial t} + (u_0^\pm \cdot \nabla) u_0^\pm + \nabla p_0^\pm = \nabla^2 u_0^\pm, \quad \text{in} \quad \Omega_\pm, \right)
\] (3.26a)

\[
\nabla \cdot u_0^\pm = 0, \quad \text{in} \quad \Omega_\pm,
\] (3.26b)

\[
\frac{\partial c_0^\pm}{\partial t} + (u_0^\pm \cdot \nabla) c_0^\pm = \frac{1}{Pe} \nabla \cdot (\nabla c^\pm), \quad \text{in} \quad \Omega_\pm,
\] (3.26c)

\[
[u_0] = 0, \quad \text{on} \quad \Gamma,
\] (3.26d)

\[-D^+ \nabla c^+ \cdot n = -D^- \nabla c^- \cdot n = K[Q(c_0)], \quad \text{on} \quad \Gamma,
\] (3.26e)

\[
[-p_0 + (n \cdot \nabla) u_0] = \frac{1}{Ca} \sigma \kappa n, \quad \text{on} \quad \Gamma,
\] (3.26f)

\[
V_n = u_0 \cdot n, \quad \text{on} \quad \Gamma.
\] (3.26g)

This illustrates that our diffusive interface model converges to the sharp interface model for mass transport with constrict diffusion condition (2.15b).

4 Numerical Method

The system (2.19) is a totally nonlinearly coupled model. In this section, we focus on developing an unconditionally energy stable numerical scheme for our proposed mathematical model based on the stabilization method [29, 20, 34, 21, 19].

In order to assure the conservation of volume of the numerical scheme, we need to rewrite some terms of system (2.19), taking into account the following relations:

\[
\begin{aligned}
\mu \nabla \phi &= \nabla (\mu \phi) - \phi \nabla \mu, \\
u \cdot \nabla \phi &= \nabla \cdot (\phi \mathbf{u}).
\end{aligned}
\] (4.1)

Then, we redefine the pressure term as

\[
\tilde{p} = p - \frac{1}{Ca} \phi \mu.
\] (4.2)

For simplicity of notation, we rewrite \(p\) instead of \(\tilde{p}\).

Given initial conditions \(\phi^0, \mu^0, u^0, p^0\) and \(c^0\), we compute \((\phi^{n+1}, \mu^{n+1}, \tilde{u}^{n+1}, u^{n+1}, p^{n+1}, c^{n+1})\) for \(n \geq 0\) by the following steps.

**Step 1.** We solve phase field variable \(\phi^{n+1}\) by the following scheme with the help of Stabilization method and Navier-Stokes equation by pressure correction method [5, 10]:

\[
Re \left( \frac{\tilde{u}^{n+1} - u^n}{\delta t} + (u^n \cdot \nabla) \tilde{u}^{n+1} + \nabla p^n = \Delta \tilde{u}^{n+1} - \frac{1}{Ca} \phi^n \nabla \mu^{n+1}, \right)
\] (4.3a)

\[
\frac{\phi^{n+1} - \phi^n}{\delta t} + \nabla \cdot (\tilde{u}^{n+1} \phi^n) = \nabla \cdot (M \nabla \mu^{n+1}),
\] (4.3b)
\[ \mu^{n+1} = -\epsilon \Delta \phi^{n+1} + \frac{s}{\epsilon} (\phi^{n+1} - \phi^n) + \frac{1}{\epsilon} G'(\phi^n), \]  
\text{(4.3c)}

with the boundary condition
\[ \nabla \phi^{n+1} \cdot \mathbf{n}|_{\partial \Omega} = 0, \quad \nabla \mu^{n+1} \cdot \mathbf{n}|_{\partial \Omega} = 0, \quad \tilde{u}^{n+1}|_{\partial \Omega} = 0. \]  
\text{(4.4)}

**Step 2.** Projection step:
\[ \text{Re} \frac{u^{n+1} - \tilde{u}^{n+1}}{\delta t} + \nabla (p^{n+1} - p^n) = 0, \]  
\text{(4.5a)}

\[ \nabla \cdot u^{n+1} = 0, \]  
\text{(4.5b)}

with boundary condition
\[ u^{n+1}|_{\partial \Omega} = 0. \]  
\text{(4.6)}

**Step 3.** \(c^{n+1}\) will be updated by the following fully implicit Euler scheme:
\[ \frac{c^{n+1} - c^n}{\delta t} + (u^{n+1} \cdot \nabla) c^{n+1} = -\nabla \cdot j^{n+1}, \]  
\text{(4.7a)}

\[ j^{n+1} = -D^{n+1} (\phi^{n+1} \nabla \mu^{n+1}), \]  
\text{(4.7b)}

\[ \mu^{n+1} = \ln c^{n+1}, \]  
\text{(4.7c)}

\[ \frac{1}{D^{n+1}} = \frac{1}{2} \left( 1 - \frac{\phi^{n+1}}{2} \right)^2 + \frac{1 - \phi^{n+1}}{2}, \]  
\text{(4.7d)}

with boundary condition
\[ \nabla c^{n+1} \cdot \mathbf{n}|_{\partial \Omega} = 0, \quad \nabla \mu^{n+1} \cdot \mathbf{n}|_{\partial \Omega} = 0. \]  
\text{(4.8)}

**Theorem 4.1.** System (4.3) – (4.8) is uniquely solvable, unconditionally stable and obey the following discrete energy law:
\[ \frac{\text{Re}}{2} (\|u^{n+1}\|^2 - \|u^n\|^2) + \frac{\delta t^2}{2\text{Re}} (\|\nabla p^{n+1}\|^2 - \|\nabla p^n\|^2) \]
\[ + \frac{1}{Ca} \left( \frac{\epsilon}{2} (\|\nabla \phi^{n+1}\|^2 - \|\nabla \phi^n\|^2) + \frac{1}{\epsilon} (G(\phi^{n+1}) - G(\phi^n), 1) \right) \]
\[ + (c^{n+1} - c^n) \ln c^{n+1}, \]
\[ = -\delta t \|\tilde{u}^{n+1}\|^2 - \delta t \frac{M}{Ca} \|\nabla \mu^{n+1}\|^2 - \delta t \int_\Omega D^{n+1} (\phi^{n+1} - \phi^n)|\nabla \mu^{n+1}|^2 dx, \]  
\text{(4.9)}

where \(\|\cdot\|\) denotes the discrete L^2 norm in domain \(\Omega\).

**Remark 4.1.** Numerical scheme (4.3) is a coupled system for \(\phi^{n+1}\) and \(\tilde{u}^{n+1}\). Block Gauss iteration method is used to compute this system efficiently.

## 5 Numerical results

In this section, some numerical experiments are conducted to illustrate validity of our model. We first check the sharp interface limit results in Section 3 by choosing smaller \(\epsilon\) and comparing with analytical solutions of sharp interface models. Then we check the convergence rate and energy stability of the numerical scheme in Section 4. Finally, the calibrated model and scheme are used to study the effect of interface permeability.

Block-centered finite difference method based on stagger mesh is adopted to discretize equations (2.19) in space. Variables \(\phi, c\) and \(p\) are located in the center of mesh, however velocity variables \(u\) and \(v\) are located on the center of edge. The main advantage of the block-centered finite difference method is it approximates the phase function, concentration function and pressure function with Neumann boundary condition to second-order accuracy, and also, it guarantees local mass conservation.
5.1 Sharp interface limit test

In this example, we take the steady state in 1D case to verify sharp interface limit of concentration function $c$. For simplicity, we first fixed the interface and only solve concentration equation (2.19e) where interface is assumed at $x_0 = 0.5$ in domain $(0, 1)$. The diffusion coefficient is taken as $D_1 = D_2 = 1$ and Dirichlet boundary condition $c_0 = 1$, $c_1 = 4$ is used. Then in this case, the exact solution of sharp interface model (1.1)-(1.2) is

$$c = \begin{cases} 
  x + 1, & x < x_0, \\
  x + 3, & x \geq x_0.
\end{cases} \quad (5.1)$$

In Figure 2, the exact solution of is shown in black solid line and the dash lines are the solutions of Eq. (2.19e) where the phase field function is chosen as $\phi = \tanh(\frac{x - x_0}{\sqrt{2\epsilon}})$ with different interface thickness $\epsilon$. In the bulk region, solutions of two methods fit very well. As $\epsilon \to 0$, the proposed diffusive model solutions change much sharper near the interface and convergence to the sharp interface solution, which is consistent with our analysis in Section 5.3.1.

![Figure 2: Sharp interface limit](image)

5.2 Comparison with sharp interface model

In this subsection, we conduct two numerical tests to compare with the results using immersed boundary methods [11]. The first experiment is 1D steady state solution of Eqs. (1.1)-(1.2) with $Q(c) = c$, $K = 1/5$. The locations of interfaces are chosen at $x_1 = 7/18$ and $x_2 = 11/18$, i.e. $\Omega^+ = (x_1, x_2)$ and $\Omega^- = (0, x_1) \cup (x_2, 1)$ and diffusion constants are $D^+ = D^- = 1$. In this case, the exact solution can be obtained as

$$c = \begin{cases} 
  -\frac{1}{11}x + 2, & x < x_1, \\
  -\frac{1}{11}x + \frac{17}{11}, & x_1 \leq x < x_2, \\
  -\frac{1}{11}(x - 1) + 1, & x \geq x_2.
\end{cases} \quad (5.2)$$

In Figure 3, the solid black line is above exact solution, blue line with circle is the immerse boundary method solution and the red line with square is the the diffusive interface solution with interface width $\epsilon = 0.01$.

We can see that the numerical solution is almost coincided with the exact solution and there is indistinguishable difference between our results and the immerse boundary result in [11].

In the next, the 2D validation is conducted where the interface is fixed as a circle with radius $r = 11/18$ and center at $x_0 = (0.5, 0.5)$. The initial condition of concentration (see Fig. 4 (a)) and parameters are set to be same as those in [11], $c(t_0, x) = G(t_0, x - x_0)$, where

$$G(t, x - x_0) = \frac{1}{4\pi Dt} \exp \left( -\frac{(x - x_0)^2}{4Dt} \right). \quad (5.3)$$
Figure 3: Steady state solution with the linear law on the interfaces located at $x_1 = 7/18$ and $x_2 = 11/18$ with $K = 0.2$, $D = 1$, $c_0 = 2$ and $c_1 = 1$. The black solid line is the exact solution, and the red dash with square is the numerical solution by phase field method, but the blue dash with circle is the numerical solution by immersed boundary method.

with

$$t_0 = 10^{-4}, \quad D = 1, \quad K = 10. \quad (5.4)$$

The computational domain is discretized by a uniform grid with size 1/128 and interface thickness $\epsilon = 0.01$.

Fig.4 (b) show the distribution of concentrations by using immerse boundary method (dash lines) [11] and proposed diffusive interface method (solid lines) at time $t = t_0 + 10^{-2}$. It illustrates that our diffusive interface model fits the immerse interface results very well for the concentration through the semi-permeable interface with restrict diffusion.

Figure 4: Comparison between phase field method and immersed boundary method for mass transfer. The fixed interface is expressed with bold cure marked by 0. (a): The initial condition of concentration that concentrates in the centre. (b): Snapshot of level curves of concentration $t = t_0 + 10^{-2}$ by using different methods. The dashed lines are level curves obtained by immersed boundary method [11] and the solid lines are the level curves obtained by proposed diffusive interface method.
5.3 Convergence study and unconditional energy stability

In this section, we conduct the convergence test and unconditional energy stable test to illustrate the effectiveness of our proposed numerical scheme. Here we use the uniform mesh, namely we use the mesh size $N_x = N_y = N$, and if not specified, uniform mesh is always tenable.

5.3.1 Convergence rate test

In this subsection, we perform some numerical experiments to support the theoretical results. We use a uniform Cartesian grid to discretize a square domain $\Omega = (0, 1)^2 \subset \mathbb{R}^2$. The initial condition is chosen as follows, (see Fig. 5)

$$\begin{align*}
\phi(x, 0) &= 0.2 + 0.5 \cos(2\pi x) \cos(2\pi y), \\
c(x, 0) &= 0.6 + 0.2 \cos(2\pi x) \cos(2\pi y), \\
u(x, 0) &= -0.25 \sin^2(\pi x) \cos(2\pi y), \\
v(x, 0) &= 0.25 \sin^2(\pi y) \cos(2\pi x),
\end{align*}$$

Periodic boundary conditions are adopted for all variables. The parameters in model (2.19) are set as 

$$\epsilon = 0.08, \quad Re = 1, \quad Ca = 1, \quad Pe = 1, \quad D^+ = D^- = 1, \quad K = A, \quad Q(c) = c.$$  

Figure 5: Initial conditions for convergence study. (a): concentration $c(x, 0)$; (b): phase field function $\phi(x, 0)$. 5.5.

The Cauchy error [28] is used to test the convergence rate. In this test method, error between two different spacial mesh sizes $h$ and $h/2$ is calculated by $\|e_\zeta\| = \|\zeta_h - \zeta_{h/2}\|$, where $\zeta$ is the function to be solved. The mesh sizes are set to be $h = 1/16, 1/32, 1/64, 1/128, 1/256$ and time step is fixed as $\delta t = 10^{-4}$. The $L^2$ and $L^\infty$ numerical errors and convergence rate at chosen time $T = 0.1$ are displayed in Table 1 and Table 2, respectively. The second order spatial accuracy is apparently observed for all the variables.

5.3.2 Unconditionally energy stable test

In this subsection, we carry out a numerical experiment to survey the unconditionally energy stability about our numerical scheme with the same initial condition and boundary conditions. The result is listed in Figure 6. Time steps are chosen from $\delta t = 0.1$ to $\delta t = 0.1 \times \frac{1}{22}$ with fixed spacial mesh size $h = 1/128$. The total energy dynamics over time with different time steps are shown in Fig. 6. It illustrates that the energy is monotonic decrease with different time steps which confirms the unconditional energy stability of the proposed scheme.

We utilize the result computed with time step $\delta t = 0.1 \times \frac{1}{12}$ to give the conservation of volume about our numerical scheme for $\phi$ as illustrated in Fig. 7. It demonstrates the volume of $\phi$ doesn’t change over time.
Table 1: The discrete $L^2$ error and convergence rate at $t = 0.1$ with initial data (5.5) and the given parameters.

![Figure 6: Unconditional energy stability with different time steps represented by different markers and colors.](image)

5.4 Effect of interface permeability

In this subsection, the calibrated model and scheme are used to study the effect of interface permeability on the diffusion of substance concentration.

We first consider a single drop with high ($K = \frac{1}{2\sigma}$), medium ($K = \frac{1}{\sigma}$) and low ($K = \frac{\delta}{2\sigma}$) permeability with $\delta = 0.02$, is suspended in a shear flow. The initial profiles of concentration and interface are given as follows (see Fig. 8),

$$\phi(x, y, t) = \tanh(0.25 - \sqrt{(x - 0.5)^2 + (y - 0.5)^2} \sqrt{2}^\epsilon),$$

$$c(x, 0) = 0.6y + 0.2.$$  

(5.7a)  
(5.7b)

with boundary condition

$$\nabla \phi \cdot n|_{y=0} = \nabla \phi \cdot n|_{y=1} = 0, \quad \phi(0, y, t) = \phi(1, y, t),$$

$$\nabla \mu \cdot n|_{y=0} = \nabla \mu \cdot n|_{y=1} = 0, \quad \mu(0, y, t) = \mu(1, y, t).$$
Figure 7: Conservation of volume of the numerical scheme with time step \( \delta t = 0.1 \times 2^{-8} \).

\[
\nabla c \cdot n|_{y=0} = \nabla c \cdot n|_{y=1} = 0, \quad c(0, y, t) = c(1, y, t),
\]
\[
u|_{y=0} = (-1, 0)^T, \quad \nu|_{y=1} = (1, 0)^T,
\]
and periodic boundary conditions are used on the left and right boundaries. The parameters read as

\[
Re = 100, \quad Ca = 1, \quad Pe = 1, \quad D^+ = 1, \quad D^- = 1, \quad \epsilon = 0.02, \quad \mathcal{M} = 0.02.
\] (5.8)

Figure 8: Initial condition for example 5.7. We set the concentration is a linear function with y-direction. The phase field function is a circle with a diffuse interface. The velocity is a shear flow.

The 2D and 3D profiles of concentration at steady states are shown in Figs. 9-10. When the interface with large permeability, the distribution of concentration is close to the linear solution where no interface is presented. This could also be observed by the direction of flux in Fig. 11 (a) and magnitude of flux in Fig. 12(a). When the permeability decreases, the flux across the interface decreases (see Fig. 12(b-c)), and are close to nonflux boundary condition such that the straight flux is disturbed around the boundary as shown in Fig. 11(b-c) and trans-membrane flux is restricted. At the steady state, due to limited flux on the interface, the inner region \( \Omega^+ \) is almost a constant (see Figs. 9-10 (c)) due to the diffusion inside and very limit flux , while the profile of concentration in the out region \( \Omega^- \) is close to the diffusion in a perforated domain.
Figure 9: Snapshots of $c$ at steady state with different permeability: $K = \frac{1}{2\sigma^3}, \frac{1}{2\sigma}$ and $\frac{\delta}{2\sigma}$.

Figure 10: 3D profile of $c$ at steady state with different permeabilities $K = \frac{1}{2\sigma^3}, \frac{1}{2\sigma}$ and $\frac{\delta}{2\sigma}$.

Figure 11: Snapshot of the magnitude for flux at steady state with different permeabilities $K = \frac{1}{2\sigma^3}, \frac{1}{2\sigma}$ and $\frac{\delta}{2\sigma}$.
In the next, we consider there are two droplets in the shear flow in a rectangular area $\Omega = [0, 2] \times [0, 1]$. The initial condition for $\phi$ is considered as

$$
\phi(x, 0) = \tanh \left( \frac{0.2 - \sqrt{(x-0.5)^2 + (y-0.7)^2}}{\sqrt{2} \epsilon} \right) + \tanh \left( \frac{0.2 - \sqrt{(x-1.5)^2 + (y-0.3)^2}}{\sqrt{2} \epsilon} \right) + 1.0.
$$

(5.9)

The permeability $K$ is chosen as $K = \frac{1}{\sigma}$. The initial conditions of $c$ and $u$ and all the parameters are chosen the same as in the former example (5.7). As shown in Fig. 13, the initial profiles of concentration and droplets are shown in Fig. 13.

In Fig. 14, the magnitude of flux overtime are presented. Due the counter flow, two droplets move closer and the merge into one droplet around time $t = 1.2$. Before $t = 1.2$, the restrict diffusion are observed on two interface and the concentrations in two droplets are two distinct constants as shown in Fig. 15 a-b. After the merge time, the droplet achieves new equilibrium of concentration (see Fig. 15 d), where the inner region flux is close to zero 14d.

6 Conclusions

In this paper, we are devoted to develop a new mathematical model for mass transfer through a semi-permeable membrane with the restricted diffusion by using diffusive interface method. The model is thermal dynamically consistent derived based on energy variation method. It turns out that the restrict diffusion on the interface could be modeled by modifying the diffusion coefficient as a function of interface permeability in the dissipation functional. The sharp interface limit for the concentration function is conducted by using the asymptotic analysis. It confirms that as the interface thickness goes to zero, the diffusive interface model converges to the sharp interface model. Besides, we establish a linear and unconditional energy stable numerical scheme to solve the obtained nonlinear coupled system. The centered-block finite difference method with stagger mesh is used for spacial discretization. The numerical

simulations ensure the asymptotic analysis results of the model and energy stability of numerical scheme. Finally, the validated model is used to study to interface permeability. It shows that our diffusive interface model could handle the restrict diffusion problem successfully and efficiently. Especially, it could deal with the case when two droplets with semipermeable interface merge together easily.
