Complex risk is a critical factor for both intelligent systems and risk management. In this paper, we consider a special class of risk statistics, named complex risk statistics. Our result provides a new approach for addressing complex risk, especially in deep neural networks. By further developing the properties related to complex risk statistics, we are able to derive dual representations for such risk.

1. Introduction

Research on complex risk is a popular topic in both intelligent systems and theoretical research, and complex risk models have attracted considerable attention, especially in deep neural networks. The quantitative calculation of risk involves two problems: choosing an appropriate complex risk model and allocating complex risk to individual components. This has led to further research on complex risk.

In a seminal paper, Artzner et al. [1, 2] first introduced the class of coherent risk measures. Later, Sun et al. [3] and Sun and Hu [4] focused on set-valued risk measures. However, traditional risk measures may fail to describe the characteristics of complex risk. This concept has promoted the study of complex risk measures. Systemic risk measures were axiomatically introduced by Chen et al. [5]. Other studies of complex risk measures include those of Acharya et al. [6], Armenti et al. [7], Biagini et al. [8], Brunnermeier and Cheridito [9], Feinstein et al. [10], Gauthier et al. [11], Tarashev et al. [12], and the references therein.

From the statistical point of view, the behaviour of a random variable can be characterized by its observations, the samples of the random variable. Heyde et al. [13, 14] first introduced the class of natural risk statistics. The corresponding dual representations are also derived. An alternative proof of the dual representations of the natural risk statistics was also derived by [15]. Later, Tian and Suo [16] obtained dual representations for convex risk statistics, and the corresponding results for quasiconvex risk statistics were obtained by [17]. Deng and Sun [18] focused on the regulator-based risk statistics for portfolios. However, all of these risk statistics are designed to quantify risk of simple component (i.e., a random variable) by its samples. A natural question is determining how to quantify complex risk by its samples.

The main focus of this paper is a new class of risk statistics, named complex risk statistics. In this context, we divide the measurement of complex risk into two steps. Our results illustrate that each complex risk statistic can be decomposed into a clustering function and a simple risk statistic, which provides a new approach for addressing complex risk. By further developing the axioms related to complex risk statistics, we are able to derive their dual representations.

The remainder of this paper is organized as follows. In Section 2, we derive the definitions related to complex risk statistics. Section 3 discusses a new measurement of complex risk statistics. Finally, in Section 4, we consider the dual representations of complex risk statistics.

2. The Definition of Complex Risk Statistics

In this section, we state the definitions related to complex risk statistics. Let \( \mathbb{R}^d \) be the \( d \)-dimensional Euclidean space, \( d \geq 1 \). For any \( x = (x_1, \ldots, x_d), y = (y_1, \ldots, y_d) \in \mathbb{R}^d, x \leq y \)
means $x_i \leq y_i$, $1 \leq i \leq d$. For any positive integer $k_i$, the element $X$ in product Euclidean space $\mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d}$ is denoted by $X := (X_1', \ldots, X_{k_1}', X_2', \ldots, X_{k_2}', \ldots, X_d')$. For any $X, Y \in \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d}$ and $1 \leq i \leq d$, $X \succ Y$ means $\sum_{j=1}^{k_i} X'_j \leq \sum_{j=1}^{k_i} Y'_j$. From now on, the addition and multiplication are all defined pointwise, $\langle X, Y \rangle = \sum_{i=1}^{d} \sum_{j=1}^{k_i} X'_j Y'_j$, $\langle x, y \rangle = \sum_{i=1}^{d} x_i y_i$. For any $X \in \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d}$, $X_{[k]} = (0, \ldots, 0, X'_1, X'_2, \ldots, X'_d, 0, \ldots, 0) \in 0^{k_1} \times 0^{k_2} \times \cdots \times 0^{k_d} \times \mathbb{R}^{k_{d+1}} \times \cdots \times 0^{k_d}$.

**Definition 1.** A simple risk statistic is a function $\varphi : \mathbb{R}^d \rightarrow [0, \infty)$ that satisfies the following properties:

(A1) Monotonicity: for any $x, y \in \mathbb{R}^d$, $x \succeq y$ implies $\varphi(x) \geq \varphi(y)$;

(A2) Convexity: for any $x, y \in \mathbb{R}^d$ and $\lambda \in [0, 1]$, $\varphi(\lambda x + (1 - \lambda)y) \leq \lambda \varphi(x) + (1 - \lambda)\varphi(y)$.

**Remark 1.** The properties A1–A2 are very well known and have been studied in detail in the study of risk statistics.

**Definition 2.** A clustering function is a function $\phi : \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d} \rightarrow \mathbb{R}^d$ that satisfies the following properties:

(B1) Monotonicity: for any $X, Y \in \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d}$, $X \succ Y$ implies $\phi(X) \succeq \phi(Y)$;

(B2) Convexity: for any $X, Y \in \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d}$ and $\lambda \in [0, 1]$, $\phi(\lambda X + (1 - \lambda)Y) \leq \lambda \phi(X) + (1 - \lambda)\phi(Y)$;

(B3) Correlation: for any $X \in \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d}$, there exists a simple risk statistic $\varphi$ such that $(\varphi \circ \phi)(X_{[k]}) = \phi(X)$.

**Definition 3.** A complex risk statistic is a function $\rho : \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d} \rightarrow \mathbb{R}$ that satisfies the following properties:

(C1) Monotonicity: for any $X, Y \in \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d}$, $X \succ Y$ implies $\rho(X) \geq \rho(Y)$;

(C2) Convexity: for any $X, Y \in \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d}$ and $\lambda \in [0, 1]$, $\rho(\lambda X + (1 - \lambda)Y) \leq \lambda \rho(X) + (1 - \lambda)\rho(Y)$;

(C3) Statistical convexity: for any $X, Y, Z \in \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d}$, $\lambda \in [0, 1]$, and $1 \leq i \leq d$, if $\rho(Z_{[k]}) = \rho(X_{[k]}) + (1 - \lambda)\rho(Y_{[k]})$, then $\rho(Z) \leq \lambda \rho(X) + (1 - \lambda)\rho(Y)$.

### 3. How to Measure Complex Risk

In this section, we derive a new approach to measure complex risk in intelligent systems. To this end, we show that each complex risk statistic can be decomposed into a simple risk statistic varrho and a clustering function $\phi$. In other words, the measurement of complex risk statistics can be simplified into two steps.

**Theorem 1.** A function $\rho : \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d} \rightarrow \mathbb{R}$ is a complex risk statistic in the case of there exists a clustering function $\phi : \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d} \rightarrow \mathbb{R}^d$ and a simple risk statistic $\varphi : \mathbb{R}^d \rightarrow \mathbb{R}$ such that $\rho$ is the composition of $\varphi$ and $\phi$, i.e.,

$$\rho(X) = (\varphi \circ \phi)(X), \quad \text{for all } X \in \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d}. \quad (1)$$

**Proof.** We first derive the “only if” part. We suppose that $\rho$ is a complex risk statistic and define a function $\phi$ by

$$\phi(X) := \left(\rho \left( X_{[k_1]} \right), \rho \left( X_{[k_2]} \right), \ldots, \rho \left( X_{[k_d]} \right) \right), \quad (2)$$

for any $X \in \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d}$. Since $\rho$ satisfies the convexity C2, it follows

$$\phi(\lambda X + (1 - \lambda)Y) = \rho \left( \lambda X_{[k_1]} + (1 - \lambda)Y_{[k_1]} \right), \ldots, \rho \left( \lambda X_{[k_d]} + (1 - \lambda)Y_{[k_d]} \right) \leq \lambda \phi(X_{[k_1]}) + (1 - \lambda)\phi(Y_{[k_1]}) \quad (3)$$

Thus, we immediately know that $\phi$ satisfies the correlation $B3$, which means $\phi$ defined above is a clustering function. Next, we illustrate that the $\rho$ defined above is a simple risk statistic. Suppose $x, y \in \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d}$ with $x \succeq y$, there exists $X, Y \in \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d}$ such that $\phi(X) = x, \phi(Y) = y$. Then, we have $\phi(X) \geq \phi(Y)$, which means $X \succ Y$ by the monotonicity of $\phi$. Thus, it follows from the property C1 of $\rho$ that
which implies \( \varrho \) satisfies the monotonicity A1. Let 
\( x, y \in \phi(R^k_1 \times R^k_2 \times \cdots \times R^k_h) \) with 
\( \phi(X) = x, \phi(Y) = y \), for any 
\( X, Y \in R^k_1 \times R^k_2 \times \cdots \times R^k_h \), which implies 
\( \phi(x) = \rho(X) \) and \( \phi(y) = \rho(Y) \). We also consider 
\( z = \lambda x + (1 - \lambda)y \) for any \( \lambda \in [0, 1] \). Thus, from the definition of \( \varrho \), there exists 
a \( Z \in R^k_1 \times R^k_2 \times \cdots \times R^k_h \) such that 
\[
\varrho(\lambda x + (1 - \lambda)y) = \rho(Z),
\]
with \( \phi(Z) = \lambda x + (1 - \lambda)y \). Hence, from the statistic 
convexity C3 of \( \rho \), we know that 
\[
\varrho(\lambda x + (1 - \lambda)y) = \rho(Z) = \lambda \rho(x) + (1 - \lambda)\rho(Y),
\]
which implies the convexity A2 of \( \rho \). Thus, \( \rho \) is a simple risk 
statistic and from (2) and (3), we have 
\[
\rho(\lambda x + (1 - \lambda)y) = \lambda \rho(x) + (1 - \lambda)\rho(Y) = \lambda \varrho(x) + (1 - \lambda)\varrho(y),
\]
for any \( \lambda \in [0, 1] \). Then, the property B3 of \( \varphi \) implies 
\[
\varphi(Z) = \lambda \varphi(x) + (1 - \lambda)\varphi(y).
\]
Thus, we have 
\[
\rho(Z) = \varrho(\lambda \varphi(x) + (1 - \lambda)\varphi(y)) = \lambda \rho(x) + (1 - \lambda)\rho(Y),
\]
which indicates \( \rho \) satisfies the property C3. Thus, the \( \rho \) 
defined above is a complex risk statistic.

**Remark 2.** Theorem 1 not only provides a decomposition 
result for complex risk statistics but also proposes an 
approach to deal with complex risk, especially in large scale 
integration. Notably, we first use the clustering function \( \phi \) to 
convert the complex system risk into simple, and then we 
quantify the simplified risk by the simple risk statistic. 
Therefore, an engineer who deals with the measurement of 
complex risk in large-scale integration can construct a 
reasonable complex risk statistic by choosing an appropriate 
clustering function and an appropriate simple risk statistic. 
The clustering function should reflect his preferences 
regarding the uncertainty of large scale integration.

In the following section, we derive the dual representations 
of complex risk statistics with the acceptance sets of \( \varphi \) 
and \( \varrho \).

### 4. Dual Representations

Before we study the dual representations of complex risk 
statistics on \( R^k_1 \times R^k_2 \times \cdots \times R^k_h \), the acceptance sets 
should be defined. Since each complex risk statistic \( \varrho \) can be 
decomposed into a clustering function \( \varphi \) and a simple risk 
statistic \( \varrho \), we need only to define the acceptance sets of \( \varphi \) 
and \( \varrho \), i.e., 
\[
\mathcal{A}_\varphi = \{ (x, y) \in R^d : \varrho(x) \leq c \}, 
\]
\[
\mathcal{A}_\varphi = \{ (y, X) \in R^d \times (R^k_1 \times R^k_2 \times \cdots \times R^k_h) : \varphi(X) \leq y \}.
\]

We will see later on that these acceptance sets can be 
used to provide complex risk statistics on 
\( R^k_1 \times R^k_2 \times \cdots \times R^k_h \). The following properties are needed in 
the subsequent study.

**Definition 4.** Let \( M \) and \( N \) be two ordered linear spaces. 
A set \( A \subset M \times N \) satisfies f-monotonicity if 
\( (m, n) \in A, q \in N \) and \( n \geq q \) implies 
\( (m, q) \in A \). A set \( A \subset M \times N \) satisfies 
b-monotonicity if \( (m, n) \in A, p \in M \), and \( p \geq m \) implies 
\( (p, n) \in A \).

**Proposition 1.** We suppose that \( \rho = \varrho \circ \varphi \) is a complex risk 
statistic with a clustering function \( \varphi : R^k_1 \times R^k_2 \times \cdots \times R^k_h \rightarrow R^d \) 
and a simple risk statistic \( \varrho : R^d \rightarrow R \). The 
corresponding acceptance sets \( \mathcal{A}_\varphi \) and \( \mathcal{A}_\varrho \) are defined by (11) 
and (12). Then, \( \mathcal{A}_\varphi \) and \( \mathcal{A}_\varrho \) are convex sets 
and they satisfy the f-monotonicity and b-monotonicity.

**Proof.** It is easy to check the abovementioned properties 
from definitions of \( \varphi \) and \( \varrho \).

The next proposition provides the primal representation 
of complex risk statistics on \( R^k_1 \times R^k_2 \times \cdots \times R^k_h \), 
considering the acceptance sets.

**Proposition 2.** We suppose that \( \rho = \varrho \circ \varphi \) is a complex risk 
statistic with a clustering function \( \varphi : R^k_1 \times R^k_2 \times \cdots \times R^k_h \rightarrow R^d \) 
and a simple risk statistic \( \varrho : R^d \rightarrow R \). The 
corresponding acceptance sets \( \mathcal{A}_\varphi \) and \( \mathcal{A}_\varrho \) are defined by (11) 
and (12). Then, for any \( X \in R^k_1 \times R^k_2 \times \cdots \times R^k_h \), 
\[
\rho(X) = \inf \{ c \in R : (c, x) \in \mathcal{A}_\varrho, (x, X) \in \mathcal{A}_\varphi \},
\]
where we set \( \inf \emptyset = +\infty \).

**Proof.** Since \( \rho = \varrho \circ \varphi \), we have 
\[
\rho(X) = \inf \{ c \in R : (\varrho \circ \varphi)(X) \leq c \}.
\]
Using the definition of \( \mathcal{A}_\varphi \), we know that 
\[
\varrho(x) = \inf \{ c \in R : (c, x) \in \mathcal{A}_\varphi \},
\]
for any \( x \in R^d \). Then, from (14) and (15), 
\[
\rho(X) = \inf \{ c \in R : (c, \varrho(X)) \in \mathcal{A}_\varphi \}.
\]
It is easy to check that 
\[
\{ c \in R : (c, \varrho(X)) \in \mathcal{A}_\varphi \} = \{ c \in R : (c, x) \in \mathcal{A}_\varphi, (x, X) \in \mathcal{A}_\varphi \}.
\]
Thus,
\[ \rho(X) = \inf \{ c \in \mathbb{R} : (c, x) \in \mathcal{A}, (x, X) \in \mathcal{A}^c \}. \]  

(18)

With Proposition 2, we now introduce the main result of this section: the dual representations of complex risk statistics on \( \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d} \).

**Theorem 2.** We suppose that \( \rho = \rho \circ \phi \) is a complex risk statistic characterized by a continue simple risk statistic \( \phi \). Then, for any \( X \in \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d} \), \( \rho(X) \) has the following form:

\[
\rho(X) = \sup_{(y, \bar{X}) \in \mathcal{D}} \{ \langle \bar{X}, X \rangle - \alpha(y, \bar{X}) \},
\]

(19)

where \( \alpha : \mathbb{R} \times (\mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d}) \rightarrow \mathbb{R} \) is defined by

\[
\alpha(y, \bar{X}) = \sup_{(c, x) \in \mathcal{A}} \left\{ -c - \langle y, x - y \rangle + \langle \bar{X}, Y \rangle \right\},
\]

(20)

\( \mathcal{D} := \left\{ (\bar{y}, \bar{X}) \in \mathbb{R}^d \times \left( \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d} \right) \right\} \),

\[ \alpha(y, \bar{X}) < \infty. \]

**Proof.** Using Proposition 2, we have

\[
\rho(X) = \inf_{(c, x) \in \mathbb{R}^d} \{ c + I_{\mathcal{A}}(c, x) + I_{\mathcal{A}}(x, X) \},
\]

(21)

for any \( X \in \mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_d} \). Furthermore, we can rewrite this formula as

\[
\rho(X) = \inf_{(c, x) \in \mathbb{R}^d} \left\{ c + I_{\mathcal{A}}(c, x) + I_{\mathcal{A}}(x, X) \right\},
\]

(22)

where the indicator function of a set \( A \in \mathcal{X} \times \mathcal{Y} \) is defined by

\[
I_A(a, b) = \begin{cases} 
0, & (a, b) \in \mathcal{X} \times \mathcal{Y}, \\
\infty, & \text{otherwise}.
\end{cases}
\]

(23)

From Proposition 1, we know that \( \mathcal{A} \) and \( \mathcal{A}^c \) are convex sets. Thus,

\[
I_{\mathcal{A}}'(\bar{c}, \bar{X}) = \sup_{(c, x) \in \mathcal{A}^c} \{ \bar{c} \cdot (c + \langle \bar{X}, x \rangle) \}, \quad \bar{c} \in \mathbb{R}, \bar{X} \in \mathbb{R}^d,
\]

\[
I_{\mathcal{A}^c}'(\bar{y}, \bar{X}) = \sup_{(c, x) \in \mathcal{A}} \{ \bar{y} \cdot (c + \langle \bar{X}, X \rangle) \},
\]

(24)

Next, since \( \phi \) is continue, it follows that \( \mathcal{A} \) is closed. Thus, by the duality theorem for conjugate functions, we have

\[
I_{\mathcal{A}^c}'(c, x) = I_{\mathcal{A}^c}''(c, x) = \sup_{(\bar{c}, \bar{X}) \in \mathbb{R}^d \times \mathbb{R}^d} \left\{ \bar{c} \cdot (c + \langle \bar{X}, x \rangle - I_{\mathcal{A}^c}'(\bar{c}, \bar{X})) \right\}
\]

\[
= \sup_{(\bar{c}, \bar{X}) \in \mathbb{R}^d \times \mathbb{R}^d} \left\{ \bar{c} \cdot (c + \langle \bar{X}, x \rangle - \sup_{(\bar{c}, \bar{X}) \in \mathbb{R}^d \times \mathbb{R}^d} \{ \bar{c} \cdot (c + \langle \bar{X}, x \rangle) \} \right\}.
\]

(25)

Similarly, we have

\[
I_{\mathcal{A}}'(c, x) = I_{\mathcal{A}}''(c, x) = \sup_{(\bar{y}, \bar{X}) \in \mathbb{R}^d \times \mathbb{R}^d} \left\{ \bar{y} \cdot (c + \langle \bar{X}, X \rangle - I_{\mathcal{A}}'(\bar{y}, \bar{X})) \right\}
\]

\[
= \sup_{(\bar{y}, \bar{X}) \in \mathbb{R}^d \times \mathbb{R}^d} \left\{ \bar{y} \cdot (c + \langle \bar{X}, X \rangle - \sup_{(\bar{y}, \bar{X}) \in \mathbb{R}^d \times \mathbb{R}^d} \{ \bar{y} \cdot (c + \langle \bar{X}, X \rangle) \} \right\}.
\]

(26)

Thus, we know that

\[
\rho(X) = \inf_{(c, x) \in \mathbb{R}^d} \left\{ c + I_{\mathcal{A}}(c, x) + I_{\mathcal{A}}(x, X) \right\}
\]

\[
= \inf_{(c, x) \in \mathbb{R}^d} \sup_{(\bar{y}, \bar{X}) \in \mathbb{R}^d \times \mathbb{R}^d} \left\{ c(1 + \bar{c}) + \langle \bar{X}, y \rangle + \langle \bar{X}, X \rangle - I_{\mathcal{A}^c}'(\bar{y}, \bar{X}) - I_{\mathcal{A}^c}'(\bar{y}, \bar{X}) \right\}.
\]

(27)
From the continuity of \( \varphi \) and the continuity of \( \phi \), we can interchange the supremum and the infimum above, i.e.,

\[
\rho(X) = \sup_{(\bar{c}, \bar{x}) \in \mathbb{R}^d} \inf_{(\bar{y}, \bar{X}) \in \mathbb{R}^{d \times (\mathbb{R}^k_1 \times \mathbb{R}^k_2 \times \cdots \times \mathbb{R}^k_r)}} \left\{ \bar{c}(1 + \bar{c}) + \langle \bar{x} + \bar{y}, x \rangle + \langle \bar{X}, X \rangle - I_{\mathcal{A}_\phi}^{\prime}(\bar{c}, \bar{x}) - I_{\mathcal{A}_\phi}^{\prime}(\bar{y}, \bar{X}) \right\}
\]

\[
= \sup_{(\bar{y}, \bar{X}) \in \mathbb{R}^{d \times (\mathbb{R}^k_1 \times \mathbb{R}^k_2 \times \cdots \times \mathbb{R}^k_r)}} \left\{ \langle \bar{X}, X \rangle - \sup_{(\bar{c}, x) \in \mathcal{A}_\phi} \left\{ -\bar{c} - \langle \bar{y}, y - x \rangle + \langle \bar{X}, X \rangle \right\} \right\}.
\]

With \( \alpha(\bar{y}, \bar{X}) \) defined by

\[
\alpha(\bar{y}, \bar{X}) = \sup_{(\bar{c}, x) \in \mathcal{A}_\phi} \left\{ -\bar{c} - \langle \bar{y}, y - x \rangle + \langle \bar{X}, X \rangle \right\} = \sup_{(\bar{c}, x) \in \mathcal{A}_\phi} \left\{ -\bar{c} - \langle \bar{y}, (y - x) \rangle + \langle \bar{X}, Y \rangle \right\},
\]

\[
\mathcal{P} = \{(\bar{y}, \bar{X}) \in \mathbb{R}^d \times (\mathbb{R}^{k_1} \times \mathbb{R}^{k_2} \times \cdots \times \mathbb{R}^{k_r}), \alpha(\bar{y}, \bar{X}) < \infty\},
\]

it immediately follows that

\[
\rho(X) = \sup_{(\bar{y}, \bar{X}) \in \mathcal{P}} \left\{ \langle \bar{X}, X \rangle - \alpha(\bar{y}, \bar{X}) \right\}.
\]  

Remark 3. Note that the proof of Theorem 1 utilized the primal representation of complex risk statistics in Proposition 2, which indicates that the acceptance sets \( \mathcal{A}_\phi \) and \( \mathcal{A}_{\phi} \) play a vital role. Thus, the dual representations of complex risk statistics \( \rho \) still dependent on the clustering function \( \phi \) and the simple risk statistic \( \varphi \).

5. Conclusions

In this paper, we derive a new class of risk statistics in intelligent systems, especially in deep neural networks, named complex risk statistics. Our results illustrate that an engineer who deals with the measurement of complex risk in intelligent systems can construct a reasonable complex risk statistic by choosing an appropriate clustering function and an appropriate simple risk statistic.
