Fixed Point Strategies in Data Science

Patrick L. Combettes, Fellow, IEEE, and Jean-Christophe Pesquet, Fellow, IEEE

Abstract—The goal of this paper is to promote the use of fixed point strategies in data science by showing that they provide a simplifying and unifying framework to model, analyze, and solve a great variety of problems. They are seen to constitute a natural environment to explain the behavior of advanced convex optimization methods as well as of recent nonlinear methods in data science which are formulated in terms of paradigms that go beyond minimization concepts and involve constructs such as Nash equilibria or monotone inclusions. We review the pertinent tools of fixed point theory and describe the main state-of-the-art algorithms for provably convergent fixed point construction. We also incorporate additional ingredients such as stochasticity, block-implementations, and non-Euclidean metrics, which provide further enhancements. Applications to signal and image processing, machine learning, statistics, neural networks, and inverse problems are discussed.

Index Terms—Convex optimization, fixed point, game theory, monotone inclusion, image recovery, inverse problems, machine learning, neural networks, nonexpansive operator, signal processing.

I. INTRODUCTION

Attempts to apply mathematical methods to the extraction of information from data can be traced back to the work of Boscovich [32], Gauss [130], Laplace [159], and Legendre [163]. Thus, in connection with the problem of estimating parameters from noisy observations, Boscovich and Laplace invented the least-deviations data fitting method, while Legendre and Gauss invented the least-squares data fitting method. On the algorithmic side, the gradient method was invented by Cauchy [55] to solve a data fitting problem in astronomy, and more or less heuristic methods have been used from then on. The early work involving provably convergent numerical solutions methods was focused mostly on quadratic minimization problems or linear programming techniques, e.g., [5], [145], [148], [222], [227]. Nowadays, general convex optimization methods have penetrated virtually all branches of data science [9], [50], [62], [77], [95], [134], [209], [217]. In fact, the optimization and data science communities have never been closer, which greatly facilitates technology transfers towards applications. Reciprocally, many of the recent advances in convex optimization algorithms have been motivated by data processing problems in signal recovery, inverse problems, or machine learning. At the same time, the design and the convergence analysis of some of the most potent splitting methods in highly structured or large-scale optimization have been based on concepts that are not found in the traditional optimization toolbox but reach deeper into nonlinear analysis. Furthermore, an increasing number of problem formulations go beyond optimization in the sense that their solutions are not optimal in the classical sense of minimizing a function but, rather, satisfy more general notions of equilibrium. Among the formulations that fall outside of the realm of standard minimization methods, let us mention variational inequality and monotone inclusion models, game theoretic approaches, neural network structures, and plug-and-play methods.

Given the abundance of activity described above and the increasingly complex formulations of some data processing problems and their solution methods, it is essential to identify general structures and principles in order to simplify and clarify the state of the art. It is the objective of the present paper to promote the viewpoint that fixed point theory constitutes an ideal technology towards this goal. Besides its unifying nature, the fixed point framework offers several advantages. On the algorithmic front, it leads to powerful convergence principles that demystify the design and the asymptotic analysis of algorithms. Furthermore, fixed point methods can be implemented using stochastic perturbations, as well as block-coordinate or block-iterative strategies which reduce the computational load and memory requirements of the iterations.

Historically, one of the first uses of fixed point theory in signal recovery is found in the bandlimited reconstruction method of [158], which is based on the iterative Banach-Picard contraction process

\[ x_{n+1} = T x_n, \]

where the operator \( T \) has Lipschitz constant \( \delta < 1 \). The importance of dealing with the more general class of nonexpansive operators, i.e., those with Lipschitz constant \( \delta = 1 \), was emphasized by Youla in [236] and [238]; see also [203], [219], [228]. Since then, many problems in data science have been modeled and solved using nonexpansive operator theory; see for instance [18], [50], [77], [101], [103], [112], [168], [187], [210], [218].

The outline of the paper is as follows. In order to make the paper as self-contained as possible, we present in Section II the essential tools and results from nonlinear analysis on which fixed point approaches are grounded. These include notions of convex analysis, monotone operator theory, and averaged operator theory. Section III provides an overview of basic fixed point principles and methods. Section IV addresses the broad class of monotone inclusion problems and their fixed point modeling. Using the tools of Section III, various splitting strategies are described, as well as block-iterative and block-coordinate algorithms. Section V discusses applications of
splitting methods to a large panel of techniques for solving structured convex optimization problems. Moving beyond traditional optimization, algorithms for Nash equilibria are investigated in Section VI. Section VII shows how fixed point models can be applied to four additional categories of data science problems that have no underlying minimization interpretation. Some brief conclusions are drawn in Section VIII. For simplicity, we have adopted a Euclidean space setting. However, most results remain valid in general Hilbert spaces up to technical adjustments.

II. NOTATION AND MATHEMATICAL FOUNDATIONS

We review the basic tools and principles from nonlinear analysis that will be used throughout the paper. Unless otherwise stated, the material of this section can be found in [19]; for convex analysis see also [196].

A. Notation

Throughout, \( \mathcal{H}, \mathcal{G}, (\mathcal{H}_i)_{1 \leq i \leq m}, \) and \( (\mathcal{G}_k)_{1 \leq k \leq q} \) are Euclidean spaces. We denote by \( 2^\mathcal{H} \) the collection of all subsets of \( \mathcal{H} \) and by \( \mathcal{H} = \mathcal{H}_1 \times \cdots \times \mathcal{H}_m \) and \( \mathcal{G} = \mathcal{G}_1 \times \cdots \times \mathcal{G}_q \) the standard Euclidean product spaces. A generic point in \( \mathcal{H} \) is denoted by \( x = (x_i)_{1 \leq i \leq m} \). The scalar product of a Euclidean space is denoted by \( \langle \cdot, \cdot \rangle \) and the associated norm by \( \| \cdot \| \). The adjoint of a linear operator \( L \) is denoted by \( L^* \). Let \( C \) be a subset of \( \mathcal{H} \). Then the distance function to \( C \) is \( d_C : x \mapsto \inf_{y \in C} \| x - y \| \) and the relative interior of \( C \), denoted by \( ri C \), is its interior relative to its affine hull.

B. Convex analysis

The central notion in convex analysis is that of a convex set: a subset \( C \) of \( \mathcal{H} \) is convex if it contains all the line segments with end points in the set, that is,

\[
(\forall x \in C)(\forall y \in C)(\forall \alpha \in [0,1]) \quad \alpha x + (1-\alpha)y \in C. \tag{2}
\]

The projection theorem is one of the most important results of convex analysis.

Theorem 1 (proportion theorem) Let \( C \) be a nonempty closed convex subset of \( \mathcal{H} \) and let \( x \in \mathcal{H} \). Then there exists a unique point \( \text{proj}_C x \in C \), called the projection of \( x \) onto \( C \), such that \( \| x - \text{proj}_C x \| = d_C(x) \). In addition, for every \( p \in \mathcal{H} \),

\[
p = \text{proj}_C x \iff \left\{ \begin{array}{l}
p \in C \\
(\forall y \in C) \langle y - p \mid x - p \rangle \leq 0.
\end{array} \right. \tag{3}
\]

Convexity for functions is inherited from convexity for sets as follows. Consider a function \( f : \mathcal{H} \rightarrow (-\infty, +\infty] \). Then \( f \) is convex if its epigraph

\[
epi f = \{ (x, \xi) \in \mathcal{H} \times \mathbb{R} \mid f(x) \leq \xi \} \tag{4}
\]

is a convex set. This is equivalent to requiring that

\[
(\forall x \in \mathcal{H})(\forall \alpha \in [0,1]) \quad f(\alpha x + (1-\alpha)y) \leq \alpha f(x) + (1-\alpha)f(y). \tag{5}
\]

If \( \text{epi} f \) is closed, then \( f \) is lower semicontinuous in the sense that, for every sequence \( (x_n)_{n \in \mathbb{N}} \) in \( \mathcal{H} \) and \( x \in \mathcal{H} \),

\[
x_n \rightarrow x \quad \Rightarrow \quad f(x) \leq \liminf f(x_n). \tag{6}
\]

Finally, we say that \( f : \mathcal{H} \rightarrow (-\infty, +\infty] \) is proper if \( \text{epi} f \neq \emptyset \), which is equivalent to

\[
\text{dom} f = \{ x \in \mathcal{H} \mid f(x) < +\infty \} \neq \emptyset. \tag{7}
\]

The class of functions \( f : \mathcal{H} \rightarrow (-\infty, +\infty] \) which are proper, lower semicontinuous, and convex is denoted by \( \Gamma_0(\mathcal{H}) \). The following result is due to Moreau [176].

Theorem 2 (proximation theorem) Let \( f \in \Gamma_0(\mathcal{H}) \) and let \( x \in \mathcal{H} \). Then there exists a unique point \( \text{prox}_f x \in \mathcal{H} \), called the proximal point of \( x \) relative to \( f \), such that

\[
f(\text{prox}_f x) + \frac{1}{2}\| x - \text{prox}_f x \| = \min_{y \in \mathcal{H}} \left( f(y) + \frac{1}{2}\| x - y \| \right). \tag{8}
\]

In addition, for every \( p \in \mathcal{H} \),

\[
p = \text{prox}_f x \iff (\forall y \in \mathcal{H}) \langle y - p \mid x - p \rangle + f(p) \leq f(y). \tag{9}
\]

The above theorem defines an operator \( \text{prox}_f \) called the proximity operator of \( f \) (see [95] for a tutorial, and [19, Chapter 24] and [84] for a detailed account with various properties). Now let \( C \) be a nonempty closed convex subset of \( \mathcal{H} \). Then its indicator function \( \iota_C \), defined by

\[
\iota_C : \mathcal{H} \rightarrow (-\infty, +\infty] : x \mapsto \begin{cases} 0, & \text{if } x \in C; \\ +\infty, & \text{if } x \notin C, \end{cases} \tag{10}
\]

lies in \( \Gamma_0(\mathcal{H}) \) and it follows from (3) and (9) that

\[
\text{prox}_C = \text{proj}_C. \tag{11}
\]

This shows that Theorem 2 generalizes Theorem 1. Let us now introduce basic convex analytical tools (see Fig. 1). The conjugate of \( f : \mathcal{H} \rightarrow (-\infty, +\infty] \) is

\[
f^* : \mathcal{H} \rightarrow (-\infty, +\infty] : u \mapsto \sup_{x \in \mathcal{H}} \langle x \mid u \rangle - f(x). \tag{12}
\]

The subdifferential of a proper function \( f : \mathcal{H} \rightarrow (-\infty, +\infty] \) is the set-valued operator \( \partial f : \mathcal{H} \rightarrow 2^\mathcal{H} \) which maps a point \( x \in \mathcal{H} \) to the set (see Fig. 2)

\[
\partial f(x) = \{ u \in \mathcal{H} \mid (\forall y \in \mathcal{H}) \langle y - x \mid u \rangle + f(x) \leq f(y) \}. \tag{13}
\]

A vector in \( \partial f(x) \) is a subgradient of \( f \) at \( x \). If \( C \) is a nonempty closed convex subset of \( \mathcal{H} \), \( N_C = \partial \iota_C \) is the normal cone operator of \( C \), that is, given \( x \in \mathcal{H} \),

\[
N_C x = \left\{ u \in \mathcal{H} \mid (\forall y \in C) \langle y-x \mid u \rangle \leq 0 \right\}, \quad \text{if } x \in C; \quad \emptyset, \quad \text{otherwise.} \tag{14}
\]

The most fundamental result in optimization is actually the following immediate consequence of (13).
Theorem 3 (Fermat’s rule) Let \( f : \mathcal{H} \to [-\infty, +\infty] \) be a proper function and let \( \text{Argmin} f \) be its set of minimizers. Then \( \text{Argmin} f = \{ x \in \mathcal{H} \mid 0 \in \partial f(x) \} \).

Theorem 4 (Moreau) Let \( f \in \Gamma_0(\mathcal{H}) \). Then \( f^* \in \Gamma_0(\mathcal{H}) \), \( f^{**} = f \), and \( \text{prox}_f + \text{prox}_{f^*} = \text{Id} \).

A function \( f \in \Gamma_0(\mathcal{H}) \) is differentiable at \( x \in \text{dom} f \) if there exists a vector \( \nabla f(x) \in \mathcal{H} \), called the gradient of \( f \) at \( x \), such that
\[
\left( \forall y \in \mathcal{H} \right) \lim_{\alpha \to 0} \frac{f(x + \alpha y) - f(x)}{\alpha} = \langle y \mid \nabla f(x) \rangle. \tag{15}
\]

Example 5 Let \( C \) be a nonempty closed convex subset of \( \mathcal{H} \). Then \( \nabla d_C^2/2 = \text{Id} - \text{proj}_C \).

Proposition 6 Let \( f \in \Gamma_0(\mathcal{H}) \) and suppose that \( x \in \mathcal{H} \) is such that \( f \) is differentiable at \( x \). Then \( \partial f(x) = \{ \nabla f(x) \} \).

We close this section by examining fundamental properties of a canonical convex minimization problem.

Proposition 7 Let \( f \in \Gamma_0(\mathcal{H}) \), let \( g \in \Gamma_0(\mathcal{G}) \), and let \( L : \mathcal{H} \to \mathcal{G} \) be linear. Suppose that \( L(\text{dom} f) \cap \text{dom} g \neq \emptyset \) and set \( S = \text{Argmin} (f + g \circ L) \). Then the following hold:

i) Suppose that \( \lim_{\|x\| \to +\infty} f(x) + g(Lx) = +\infty \). Then \( S \neq \emptyset \).

ii) Suppose that \( \text{ri}(L(\text{dom} f)) \cap \text{ri}(\text{dom} g) \neq \emptyset \). Then \( S = \{ x \in \mathcal{H} \mid 0 \in \partial f(x) + L^* (\partial g(Lx)) \} = \{ x \in \mathcal{H} \mid (\exists v \in \partial g(Lx)) \ - \ L^* v \in \partial f(x) \} \).

C. Nonexpansive operators

We introduce the main classes of operators pertinent to our discussion. First, we need to define the notion of a relaxation for an operator.

Definition 8 Let \( T : \mathcal{H} \to \mathcal{H} \) and let \( \lambda \in [0, +\infty[ \). Then the operator \( R = \text{Id} + \lambda (T - \text{Id}) \) is a relaxation of \( T \). If \( \lambda \leq 1 \), then \( R \) is an underrelaxation of \( T \) and, if \( \lambda \geq 1 \), \( R \) is an overrelaxation of \( T \); in particular, if \( \lambda = 2 \), \( R \) is the reflection of \( T \).

Definition 9 Let \( \alpha \in [0, 1] \). An \( \alpha \)-relaxation sequence is a sequence \( (\lambda_n)_{n \in \mathbb{N}} \) in \( [0, 1/\alpha[ \) such that \( \sum_{n \in \mathbb{N}} \lambda_n (1 - \alpha \lambda_n) = +\infty \).

Example 10 Let \( \alpha \in [0, 1] \) and let \( (\lambda_n)_{n \in \mathbb{N}} \) be a sequence in \( [0, +\infty[ \). Then \( (\lambda_n)_{n \in \mathbb{N}} \) is an \( \alpha \)-relaxation sequence in each of the following cases:

i) \( \alpha < 1 \) and \( \forall n \in \mathbb{N} \) \( \lambda_n = 1 \).

ii) \( \forall n \in \mathbb{N} \) \( \lambda_n = \lambda \in [0, 1/\alpha[ \).

iii) \( \inf_{n \in \mathbb{N}} \lambda_n > 0 \) and \( \sup_{n \in \mathbb{N}} \lambda_n < 1/\alpha \).

iv) There exists \( \varepsilon \in [0, 1/\alpha[ \) such that \( \forall n \in \mathbb{N} \) \( \varepsilon/\sqrt{n + 1} \leq \lambda_n \leq 1/\alpha - \varepsilon/\sqrt{n + 1} \).

An operator \( T : \mathcal{H} \to \mathcal{H} \) is Lipschitzian with constant \( \delta \in [0, +\infty[ \) if
\[
(\forall x \in \mathcal{H}) (\forall y \in \mathcal{H}) \ ||T x - T y|| \leq \delta \|x - y\|. \tag{16}
\]

If \( \delta < 1 \) above, then \( T \) is a Banach contraction (also called a strict contraction). If \( \delta = 1 \), that is,
\[
(\forall x \in \mathcal{H}) (\forall y \in \mathcal{H}) \ |\langle x - y \mid T x - T y \rangle| \geq \beta \|T x - T y\|^2, \tag{18}
\]

then \( T \) is nonexpansive. On the other hand, \( T \) is cocoercive with constant \( \beta \in [0, +\infty[ \) if
\[
(\forall x \in \mathcal{H}) (\forall y \in \mathcal{H}) \ |\langle x - y \mid T x - T y \rangle| \geq \beta \|T x - T y\|^2, \tag{18}
\]

If \( \beta = 1 \) in (18), then \( T \) is firmly nonexpansive. Alternatively, \( T \) is firmly nonexpansive if
\[
(\forall x \in \mathcal{H}) (\forall y \in \mathcal{H}) \ |\langle x - y \mid T x - T y \rangle| \leq \|x - y\|^2 - \|T (\text{Id} - T) x - (\text{Id} - T) y\|^2. \tag{19}
\]
Proposition 12 Let $\delta \in [0,1[$, let $T: \mathcal{H} \to \mathcal{H}$ be $\delta$-Lipschitzian, and set $\alpha = (\delta + 1)/2$. Then $T$ is $\alpha$-averaged.

Proposition 13 Let $T: \mathcal{H} \to \mathcal{H}$, let $\beta \in [0, +\infty]$, and let $\gamma \in [0, 2\beta]$. Then $T$ is $\beta$-cocoercive if and only if if $\text{Id} - \gamma T$ is $\gamma/(2\beta)$-averaged.

It follows from the Cauchy-Schwarz inequality that a $\beta$-cocoercive operator is $\beta^{-1}$-Lipschitzian. In the case of gradients of convex functions, the converse is also true.

Proposition 14 (Baillon-Haddad) Let $f: \mathcal{H} \to \mathbb{R}$ be a differentiable convex function and such that $\nabla f$ is $\beta^{-1}$-Lipschitzian for some $\beta \in [0, +\infty]$. Then $\nabla f$ is $\beta$-cocoercive.

We now describe operations that preserve averagedness and cocoercivity.

Proposition 15 Let $T: \mathcal{H} \to \mathcal{H}$, let $\alpha \in [0, 1[$, and let $\lambda \in [0, 1/\alpha]$. Then $T$ is $\alpha$-averaged if and only if $(1 - \lambda)\text{Id} + \lambda T$ is $\lambda\alpha$-averaged.

Proposition 16 For every $i \in \{1, \ldots, m\}$, let $\alpha_i \in [0, 1[$, let $\omega_i \in [0, 1]$, and let $T_i: \mathcal{H} \to \mathcal{H}$ be $\alpha_i$-averaged. Suppose that $\sum_{i=1}^m \omega_i = 1$ and set $\alpha = \sum_{i=1}^m \omega_i\alpha_i$. Then $\sum_{i=1}^m \omega_i T_i$ is $\alpha$-averaged.

Example 17 For every $i \in \{1, \ldots, m\}$, let $\omega_i \in [0, 1]$ and let $\text{Id} - \gamma T_i$ be firmly nonexpansive. Suppose that $\sum_{i=1}^m \omega_i = 1$. Then $\sum_{i=1}^m \omega_i T_i$ is firmly nonexpansive.

Proposition 18 For every $i \in \{1, \ldots, m\}$, let $\alpha_i \in [0, 1[$, and let $T_i: \mathcal{H} \to \mathcal{H}$ be $\alpha_i$-averaged. Set

$$T = T_1 \circ \cdots \circ T_m \quad \text{and} \quad \alpha = \frac{1}{1 + \sum_{i=1}^m 1/\alpha_i - \sum_{i=1}^m \alpha_i}. \quad (25)$$

Then $T$ is $\alpha$-averaged.

Example 19 Let $\alpha_1 \in [0, 1[$, let $\alpha_2 \in [0, 1[$, let $T_1: \mathcal{H} \to \mathcal{H}$ be $\alpha_1$-averaged, and let $T_2: \mathcal{H} \to \mathcal{H}$ be $\alpha_2$-averaged. Set

$$T = T_1 \circ T_2 \quad \text{and} \quad \alpha = \frac{\alpha_1 + \alpha_2 - 2\alpha_1\alpha_2}{1 - \alpha_1\alpha_2}. \quad (26)$$

Then $T$ is $\alpha$-averaged.

Proposition 20 ([113]) Let $T_1: \mathcal{H} \to \mathcal{H}$ and $T_2: \mathcal{H} \to \mathcal{H}$ be firmly nonexpansive, let $\alpha_3 \in [0, 1[$, and let $T_3: \mathcal{H} \to \mathcal{H}$ be $\alpha_3$-averaged. Set $\alpha = 1/(2 - \alpha_3)$ and

$$T = T_1 \circ (T_2 - \text{Id} + T_3 \circ T_2) + \text{Id} - T_2. \quad (27)$$

Then $T$ is $\alpha$-averaged.

Proposition 21 For every $k \in \{1, \ldots, q\}$, let $0 \neq L_k: \mathcal{H} \to \mathcal{G}_k$ be linear, let $\beta_k \in [0, +\infty[$, and let $T_k: \mathcal{G}_k \to \mathcal{G}_k$ be $\beta_k$-cocoercive. Set

$$T = \sum_{k=1}^q T_k \circ L_k \quad \text{and} \quad \beta = \frac{1}{\sum_{k=1}^q \beta_k \|L_k\|^2}. \quad (28)$$

The relationships between the different notions of nonlinear operators discussed so far are depicted in Fig. 3. The next propositions provide some connections between cocoercivity and averagedness.
Then the following hold:

i) $T$ is $\beta$-cocoercive [19].

ii) Suppose that $\sum_{k=1}^{q} \|L_k\|^2 \leq 1$ and that the operators $(T_k)_{1 \leq k \leq q}$ are firmly nonexpansive. Then $T$ is firmly nonexpansive [19].

iii) Suppose that $\sum_{k=1}^{q} \|L_k\|^2 \leq 1$ and that $(T_k)_{1 \leq k \leq q}$ are proximity operators. Then $T$ is a proximity operator [84].

Remark 22 The statement of Proposition 21(iii) can be made more precise [84]. To wit, for every $k \in \{1, \ldots, q\}$, let $\omega_k \in [0, +\infty[$, let $0 \neq L_k : H \to G_k$ be linear, let $g_k \in \Gamma_0(G_k)$, and let $h_k : v \mapsto \inf_{w \in g_k} (g_k(w) + \|v - w\|^2/2)$ be the Moreau envelope of $g_k$. Then, if $\sum_{k=1}^{q} \omega_k \|L_k\|^2 \leq 1$, we have

$$
\sum_{k=1}^{q} \omega_k (L_k^* \circ \text{prox}_{g_k} \circ L_k) = \text{prox}_f,
$$

where

$$
f = \left( \sum_{k=1}^{q} \omega_k h_k \circ L_k \right)^* - \|\cdot\|^2/2.\hspace{1cm}(29)
$$

Let $T : H \to H$ and let

$$
\text{Fix } T = \{ x \in H \mid Tx = x \} \hspace{1cm}(30)
$$

be its set of fixed points. If $T$ is a Banach contraction, then it admits a unique fixed point. However, if $T$ is merely nonexpansive, the situation is quite different. Indeed, a nonexpansive operator may have no fixed point (take $T : x \mapsto x + z$, with $z \neq 0$), exactly one (take $T = -\text{Id}$), or infinitely many (take $T = \text{Id}$). Even those operators which are firmly nonexpansive can fail to have fixed points.

Example 23 $T : \mathbb{R} \to \mathbb{R} : x \mapsto (x + \sqrt{x^2 + 4})/2$ is firmly nonexpansive and $\text{Fix } T = \emptyset$.

Proposition 24 Let $T : H \to H$ be nonexpansive. Then $\text{Fix } T$ is closed and convex.

Proposition 25 Let $(T_i)_{1 \leq i \leq m}$ be nonexpansive operators from $H$ to $H$, and let $(\omega_i)_{1 \leq i \leq m}$ be real numbers in $[0, 1]$ such that $\sum_{i=1}^{m} \omega_i = 1$. Suppose that $\bigcap_{i=1}^{m} \text{Fix } T_i \neq \emptyset$. Then $\text{Fix } (\sum_{i=1}^{m} \omega_i T_i) = \bigcap_{i=1}^{m} \text{Fix } T_i$.

Proposition 26 For every $i \in \{1, \ldots, m\}$, let $\alpha_i \in [0, 1]$ and let $T_i : H \to H$ be $\alpha_i$-averaged. Suppose that $\bigcap_{i=1}^{m} \text{Fix } T_i \neq \emptyset$. Then $\text{Fix } (T_1 \circ \cdots \circ T_m) = \bigcap_{i=1}^{m} \text{Fix } T_i$.

D. Monotone operators

Let $A : H \to 2^H$ be a set-valued operator. Then $A$ is described by its graph

$$
\text{gra } A = \{ (x, u) \in H \times H \mid u \in Ax \}, \hspace{1cm}(31)
$$

and its inverse $A^{-1}$, defined by the relation

$$
(\forall (x, u) \in H \times H) \hspace{0.5cm} x \in A^{-1} u \iff u \in Ax, \hspace{1cm}(32)
$$

always exists (see Fig. 4). The operator $A$ is monotone if

$$
(\forall (x, u) \in \text{gra } A) (\forall (y, v) \in \text{gra } A) \hspace{0.5cm} \langle x - y \mid u - v \rangle \geq 0, \hspace{1cm}(33)
$$

in which case $A^{-1}$ is also monotone.

Example 27 Let $f : H \to [-\infty, +\infty]$ be a proper function, let $(x, u) \in \text{gra } \partial f$, and let $(y, v) \in \text{gra } \partial f$. Then (13) yields

$$
\begin{cases}
\langle x - y \mid u - v \rangle + f(y) \geq f(x) \\
\langle y - x \mid v - u \rangle + f(x) \geq f(y)
\end{cases} \hspace{1cm}(34)
$$

Adding these inequality yields $\langle x - y \mid u - v \rangle \geq 0$, which shows that $\partial f$ is monotone.

A natural question is whether the operator obtained by adding a point to the graph of a monotone operator $A : H \to 2^H$ is still monotone. If it is not, then $A$ is said to be maximally monotone. Thus, $A$ is maximally monotone if, for every $(x, u) \in H \times H$,

$$
(x, u) \in \text{gra } A \iff (\forall (y, v) \in \text{gra } A) \hspace{0.5cm} \langle x - y \mid u - v \rangle \geq 0. \hspace{1cm}(35)
$$

Fig. 4: Left: Graph of a (nonmonotone) set-valued operator. Right: Graph of its inverse.

Fig. 5: Left: Graph of a monotone operator which is not maximally monotone: we can add the point $(x_0, y_0)$ to its graph and still get a monotone graph. Right: Graph of a maximally monotone operator: adding any point to this graph destroys its monotonicity.
These notions are illustrated in Fig. 5. Let us now provide some basic examples of maximally monotone operators, starting with the subdifferential of (13) (see Fig. 2).

Example 28 (Moreau) Let \( f \in \Gamma_0(\mathcal{H}) \). Then \( \partial f \) is maximally monotone and \( (\partial f)^{-1} = \partial f^* \).

Example 29 Let \( T : \mathcal{H} \to \mathcal{H} \) be monotone and continuous. Then \( T \) is maximally monotone. In particular, if \( T \) is cocoercive, it is maximally monotone.

Example 30 Let \( T : \mathcal{H} \to \mathcal{H} \) be nonexpansive. Then \( \text{Id} - T \) is maximally monotone.

Example 31 Let \( T : \mathcal{H} \to \mathcal{H} \) be linear (hence continuous) and positive in the sense that \((\forall x \in \mathcal{H}) \langle x | Tx \rangle \geq 0\). Then \( T \) is maximally monotone. In particular, if \( T \) is skew, i.e., \( T^* = -T \), then it is maximally monotone.

Given \( A : \mathcal{H} \to 2^\mathcal{H} \), the resolvent of \( A \) is the operator \( J_A = (\text{Id} + A)^{-1} \), that is,

\[
(\forall (x, p) \in \mathcal{H} \times \mathcal{H}) \quad p \in J_A x \iff x - p \in Ap.
\]

In addition, the reflected resolvent of \( A \) is

\[
R_A = 2J_A - \text{Id}.
\]

A profound result which connects monotonicity and nonexpansiveness is Minty’s theorem [172]. It implies that if, \( A : \mathcal{H} \to 2^\mathcal{H} \) is maximally monotone, then \( J_A \) is single-valued, defined everywhere on \( \mathcal{H} \), and firmly nonexpansive.

Theorem 32 (Minty) Let \( T : \mathcal{H} \to \mathcal{H} \). Then \( T \) is firmly nonexpansive if and only if it is the resolvent of a maximally monotone operator \( A : \mathcal{H} \to 2^\mathcal{H} \).

Example 33 Let \( f \in \Gamma_0(\mathcal{H}) \). Then \( J_{\delta f} = \text{prox}_f \).

Let \( f \) and \( g \) be functions in \( \Gamma_0(\mathcal{H}) \) which satisfy the constraint qualification \( \text{ri}(\text{dom } f) \cap \text{ri}(\text{dom } g) \neq \emptyset \). In view of Proposition 7(ii) and Example 28, the minimizers of \( f + g \) are precisely the solutions to the inclusion \( 0 \in Ax + Bx \) involving the maximally monotone operators \( A = \partial f \) and \( B = \partial g \). Hence, it may seem that in minimization problems the theory of subdifferentials should suffice to analyze and solve problems without invoking general monotone operator theory. As discussed in [84], this is not the case and monotone operators play an indispensable role in various aspects of convex minimization. We give below an illustration of this fact in the context of Proposition 7.

Example 34 ([41]) Given \( f \in \Gamma_0(\mathcal{H}), g \in \Gamma_0(\mathcal{G}) \), and a linear operator \( L : \mathcal{H} \to \mathcal{G} \), the objective is to minimize

\[
\min_{x \in \mathcal{H}} f(x) + g(Lx)
\]

using \( f \) and \( g \) separately by means of their respective proximity operators. To this end, let us bring into play the Fenchel-Rockafellar dual problem

\[
\min_{v \in \mathcal{G}} f^*(-L^*v) + g^*(v).
\]

We derive from [19, Theorem 19.1] that, if \((x,v) \in \mathcal{H} \times \mathcal{G}\) solves the inclusion

\[
\begin{bmatrix} 0 \\ 0 \end{bmatrix} \in \begin{bmatrix} \partial f & 0 \\ 0 & \partial g^* \end{bmatrix} \begin{bmatrix} x \\ v \end{bmatrix} + \begin{bmatrix} 0 & -L^* \\ -L & 0 \end{bmatrix} \begin{bmatrix} x \\ v \end{bmatrix},
\]

then \( x \) solves (38) and \( v \) solves (39). Now introduce the variable \( z = (x,v) \), the function \( \Gamma_0(\mathcal{H} \times \mathcal{G}) \ni h : z \mapsto f(x) + g^*(v) \), the operator \( A = \partial h \), and the skew operator \( B : z \mapsto (L^*v, -Lx) \). Then it follows from Examples 28 and 31 that (40) can be written as the maximally monotone inclusion \( 0 \in Az + Bz \), which does not correspond to a minimization problem since \( B \) is not a gradient [19, Proposition 2.58]. As a result, genuine monotone operator splitting methods were employed in [41] to solve (40) and, thereby, (38) and (39). Applications of this framework can be found in image restoration [181] and in empirical mode decomposition [188].

Example 35 The primal-dual pair (38)–(39) can be exploited in various ways; see for instance [61], [85], [86], [157]. A simple illustration is found in sparse signal recovery and machine learning, where one often aims at solving (38) by choosing \( g \) to be a norm \( ||| \cdot ||| \) [4], [9], [91], [118], [170]. Now let \( ||| \cdot |||_* : \mathcal{G} \to \mathbb{R} : v \mapsto \sup_{|||y||| \leq 1} \langle y | v \rangle \) be the dual norm and let \( B_* = \{ v \in \mathcal{G} : |||v|||_* \leq 1 \} \) be the associated unit ball. Then (39) is the constrained optimization problem

\[
\min_{v \in B_*} f^*(-L^*v).
\]

This dual formulation underlies several investigations, e.g., [121], [178].

III. FIXED POINT ALGORITHMS

We review the main relevant algorithms to construct fixed points.

A. Basic iteration schemes

First, we recall that finding a fixed point of a Banach contraction is relatively straightforward via the standard Banach-Picard iteration scheme (1).

Theorem 36 ([19]) Let \( \delta \in ]0,1[ \) be a contraction, and let \( x_0 \in \mathcal{H} \). Set

\[
(\forall n \in \mathbb{N}) \quad x_{n+1} = T x_n.
\]

Then \( T \) has a unique fixed point \( \overline{x} \) and \( x_n \to \overline{x} \). More precisely, \((\forall n \in \mathbb{N}) \quad |||x_n - \overline{x}||| \leq \delta^n ||| x_0 - \overline{x} |||.

If \( T \) is merely nonexpansive (i.e., \( \delta = 1 \)) with \( \text{Fix} T \neq \emptyset \), Theorem 36 fails. For instance, let \( T \neq \text{Id} \) be a rotation in the Euclidean plane. Then it is nonexpansive with \( \text{Fix} T = \{0\} \) but the sequence \((x_n)_{n \in \mathbb{N}}\) constructed by the successive approximation process (42) does not converge. Such scenarios can be handled via the following result.
Theorem 37 ([19]) Let $\alpha \in [0,1]$, let $T: \mathcal{H} \to \mathcal{H}$ be an $\alpha$-averaged operator such that $\text{Fix} T \neq \emptyset$, let $(\lambda_n)_{n \in \mathbb{N}}$ be an $\alpha$-relaxation sequence. Set
\[ (\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \lambda_n (Tx_n - x_n). \] (43)
Then $(x_n)_{n \in \mathbb{N}}$ converges to a point in $\text{Fix} T$.

Remark 38 In connection with Theorems 36 and 37, let us make the following observations.

i) If $\alpha < 1$ in Theorem 37, choosing $\lambda_n = 1$ in (43) (see Example 10(i)) yields (42).

ii) In contrast with Theorem 36, the convergence in Theorem 37 is not linear in general [21], [30].

iii) When $\alpha = 1$, (43) is known as the Krasnosel’skiĭ-Mann iteration.

Next, we present a more flexible fixed point theorem which involves iteration-dependent composite averaged operators.

Theorem 39 ([106]) Let $\varepsilon \in [0,1/2]$ and let $x_0 \in \mathcal{H}$. For every $n \in \mathbb{N}$, let $\alpha_1,n \in [0,1/(1+\varepsilon)]$, let $\alpha_2,n \in [0,1/(1+\varepsilon)]$, let $T_{1,n}: \mathcal{H} \to \mathcal{H}$ be $\alpha_1,n$-averaged, and let $T_{2,n}: \mathcal{H} \to \mathcal{H}$ be $\alpha_2,n$-averaged. In addition, for every $n \in \mathbb{N}$, let
\[ \lambda_n \in \left[ \varepsilon, (1-\varepsilon)(1+\varepsilon\alpha_n)/\alpha_n \right], \] (44)
where $\alpha_n = (\alpha_1,n + \alpha_2,n - 2\alpha_1,n\alpha_2,n)/(1-\alpha_1,n\alpha_2,n)$, and set
\[ x_{n+1} = x_n + \lambda_n (T_{1,n}(T_{2,n}x_n) - x_n). \] (45)
Suppose that $S = \bigcap_{n \in \mathbb{N}} \text{Fix} (T_{1,n} \circ T_{2,n}) \neq \emptyset$. Then the following hold:

i) $(\forall x \in S) \sum_{n \in \mathbb{N}} \| T_{2,n}x_n - x_n - T_{2,n}x_n + x_n \|^2 < +\infty$.

ii) Suppose that a subsequence of $(x_n)_{n \in \mathbb{N}}$ converges to a point in $S$. Then $(x_n)_{n \in \mathbb{N}}$ converges to a point in $S$.

Remark 40 The assumption in Theorem 39(ii) holds in particular when, for every $n \in \mathbb{N}$, $T_{1,n} = T_1$ and $T_{2,n} = T_2$.

A variant of Theorem 37 is obtained by considering the composition of $m$ operators.

Theorem 41 ([82]) For every $i \in \{1, \ldots, m\}$, let $\alpha_i \in [0,1]$ and let $T_i: \mathcal{H} \to \mathcal{H}$ be $\alpha_i$-averaged. Let $x_0 \in \mathcal{H}$, suppose that $\text{Fix} (T_1 \circ \cdots \circ T_m) \neq \emptyset$, and iterate
\[ \begin{align*}
& x_{mn+1} = T_m x_{mn} \\
& x_{mn+2} = T_{m-1} x_{mn+1} \\
& \quad \vdots \\
& x_{mn+m-1} = T_2 x_{mn+m-2} \\
& x_{mn+m} = T_1 x_{mn+m-1}.
\end{align*} \] (46)
Then $(x_{mn})_{n \in \mathbb{N}}$ converges to a point $\overline{x}_1$ in $\text{Fix} (T_1 \circ \cdots \circ T_m)$. Now set $\overline{x}_m = T_m \overline{x}_1$, $\overline{x}_{m-1} = T_{m-1} \overline{x}_m$, $\ldots$, $\overline{x}_3 = T_2 \overline{x}_2$. Then, for every $i \in \{1, \ldots, m-1\}$, $(x_{mn+i})_{n \in \mathbb{N}}$ converges to $\overline{x}_{m+1-i}$.

B. Algorithms for fixed point selection

The algorithms discussed so far construct an unspecified fixed point of a nonexpansive operator $T: \mathcal{H} \to \mathcal{H}$. In some applications, one may be interested in finding a specific fixed point, for instance one of minimum norm or more generally, one that minimizes some quadratic function [5], [81]. One will find in [81] several algorithms to minimize convex quadratic functions over fixed point sets, as well as signal recovery applications. More generally, one may wish to minimize a strictly convex function $g \in C_0(\mathcal{H})$ over the closed convex set (see Proposition 24) $\text{Fix} T$, i.e.,
\[ \min_{x \in \text{Fix} T} g(x). \] (47)
Instances of such formulations can be found in signal interpolation [183] and machine learning [177]. Algorithms to solve (47) have been proposed in [79], [146], [230] under various hypotheses. Here is an example.

Proposition 42 ([230]) Let $T: \mathcal{H} \to \mathcal{H}$ be nonexpansive, let $g: \mathcal{H} \to \mathbb{R}$ be strongly convex and differentiable with a Lipschitzian gradient, let $x_0 \in \mathcal{H}$, and let $(\alpha_n)_{n \in \mathbb{N}}$ be a sequence in $[0,1]$ such that $\alpha_n \to 0$, $\sum_{n \in \mathbb{N}} \alpha_n = +\infty$, and $\sum_{n \in \mathbb{N}} |\alpha_{n+1} - \alpha_n| < +\infty$. Suppose that (47) has a solution and iterate
\[ (\forall n \in \mathbb{N}) \quad x_{n+1} = Tx_n - \alpha_n \nabla g(Tx_n). \] (48)
Then $(x_n)_{n \in \mathbb{N}}$ converges to the solution to (47).

C. A fixed point method with block operator updates

We turn our attention to a composite fixed point problem.

Problem 43 Let $(\omega_i)_{1 \leq i \leq m}$ be real numbers in $[0,1]$ such that $\sum_{i=1}^m \omega_i = 1$. For every $i \in \{0, \ldots, m\}$, let $T_i: \mathcal{H} \to \mathcal{H}$ be $\alpha_i$-averaged for some $\alpha_i \in [0,1]$. The task is to find a fixed point of $T_0 \circ \cdots \circ T_m$, assuming that such a point exists.

A simple strategy to solve Problem 43 is to set $R = \sum_{i=1}^m \omega_i T_i$, observe that $R$ is averaged by Proposition 16, and then use Theorem 39 and Remark 40 to find a fixed point of $T_0 \circ R$. This, however, requires the activation of the $m$ operators $(T_i)_{1 \leq i \leq m}$ to evaluate $R$ at each iteration, which is a significant computational burden when $m$ is sizable. In the degenerate case when the operators $(T_i)_{0 \leq i \leq m}$ have common fixed points, Problem 43 amounts to finding such a point (see Propositions 25 and 26) and this can be done using the strategies devised in [15], [20], [77], [156] which require only the activation of blocks of operators at each iteration. Such approaches fail in our more challenging setting, which assumes only that $\text{Fix} (T_0 \circ \cdots \circ T_m) \neq \emptyset$. Using mean iteration techniques from [88], it is nonetheless possible to devise an algorithm which operates by updating only a block of operators $(T_i)_{i \in I_k}$ at iteration $n$.

Theorem 44 ([90]) Consider the setting of Problem 43. Let $M$ be a strictly positive integer and let $(I_n)_{n \in \mathbb{N}}$ be a sequence of nonempty subsets of $\{1, \ldots, m\}$ such that
\[ \bigcup_{k = n}^{n+M-1} I_k = \{1, \ldots, m\}. \] (49)
Let \( x_0 \in \mathcal{H} \), let \((t_{i,-1})_{1 \leq i \leq m} \in \mathcal{H}^m\), and iterate

\[
\begin{align*}
\text{for } n = 0, 1, \ldots \\
\quad \text{for every } i \in I_n \\
\qquad t_{i,n} = T_i x_n \\
\quad \text{for every } i \in \{1, \ldots, m\} \setminus I_n \\
\qquad t_{i,n} = t_{i,n-1} \\
\quad x_{n+1} = T_0 \left( \sum_{i=1}^m \omega_i t_{i,n} \right).
\end{align*}
\]

(50)

Then the following hold:

i) Let \( x \) be a solution to Problem 43 and let \( i \in \{1, \ldots, m\} \). Then \( x_n - T_i x_n \rightarrow x - T_i x \).

ii) \((x_n)_{n \in \mathbb{N}} \) converges to a solution to Problem 43.

iii) Suppose that, for some \( i \in \{0, \ldots, m\} \), \( T_i \) is a Banach contraction. Then \((x_n)_{n \in \mathbb{N}} \) converges linearly to the unique solution to Problem 43.

At iteration \( n \), \( I_n \) is the set of indices of operators to be activated. The remaining operators are not used and their most recent evaluations are recycled to form the update \( x_{n+1} \). Condition (49) imposes the mild requirement that each operator in \((T_i)_{1 \leq i \leq m}\) be evaluated at least once over the course of any \( M \) consecutive iterations. The choice of \( M \) is left to the user.

D. Perturbed fixed point methods

For various modeling or computational reasons, exact evaluations of the operators in fixed point algorithms may not be possible. Such perturbations can be modeled by deterministic additive errors [82], [155], [169] but also by stochastic ones [97], [123]. Here is a stochastically perturbed version of Theorem 37, which is a straightforward variant of [97, Corollary 2.7].

\textbf{Theorem 46 (97)} Let \( \alpha \in [0, 1] \), let \( \epsilon \in [0, 1/2] \), and let \( T_1: \mathcal{H} \rightarrow \mathcal{H} \) be an \( \alpha \)-averaged operator such that \( \text{Fix} T \neq \emptyset \), and let \((\lambda_n)_{n \in \mathbb{N}} \) be an \( \alpha \)-relaxation sequence. Let \( x_0 \) and \((\epsilon_n)_{n \in \mathbb{N}} \) be \( \mathcal{H} \)-valued random variables. Set

\[
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \lambda_n (T x_n + \epsilon_n - x_n).
\]

(51)

Suppose that \( \sum_{n \in \mathbb{N}} \lambda_n \sqrt{\mathbb{E}(\|\epsilon_n\|^2 | \mathcal{X}_n)} < \infty \) a.s., where \( \mathcal{X}_n \) is the \( \sigma \)-algebra generated by \((x_0, \ldots, x_n) \). Then \((x_n)_{n \in \mathbb{N}} \) converges a.s. to a \((\text{Fix} T)\)-valued random variable.

E. Random block-coordinate fixed point methods

We have seen in Section III-C that the computational cost per iteration could be reduced in certain fixed point algorithms by updating only some of the operators involved in the model. In this section, we present another approach to reduce the iteration cost by considering scenarios in which the underlying Euclidean space \( \mathcal{H} \) is decomposable in \( m \) factors \( \mathcal{H} = \mathcal{H}_1 \times \cdots \times \mathcal{H}_m \). In the spirit of the Gauss-Seidel algorithm, one can explore the possibility of activating only some of the coordinates of certain operators at each iteration of a fixed point method. The potential advantages of such a procedure are a reduced computational cost per iteration, reduced memory requirements, and an increased implementation flexibility.

Consider the basic update process

\[
x_{n+1} = T_n x_n,
\]

(52)

under the assumption that the operator \( T_n \) is decomposable explicitly as

\[
T_n: \mathcal{H} \rightarrow \mathcal{H}: x \mapsto (T_{1,n} x, \ldots, T_{m,n} x),
\]

(53)

with \( T_{i,n}: \mathcal{H} \rightarrow \mathcal{H}_i \). Updating only some coordinates is performed by modifying iteration (52) as

\[
(\forall i \in \{1, \ldots, m\}) \quad x_{i,n+1} = x_{i,n} + \epsilon_{i,n} (T_{i,n} x_n - x_{i,n}),
\]

(54)

where \( \epsilon_{i,n} \in \{0, 1\} \) signals the activation of the \( i \)-th coordinate of \( x_n \). If \( \epsilon_{i,n} = 1 \), the \( i \)-th component is updated whereas, if \( \epsilon_{i,n} = 0 \), it is unchanged. The main roadblock with such an approach is that the nonexpansiveness property of an operator is usually destroyed by coordinate sampling. To circumvent this problem, a possibility is to make the activation variables random, which results in a stochastic algorithm for which almost sure convergence holds [97], [149].

\textbf{Theorem 46 (97)} Let \( \alpha \in [0, 1] \), let \( \epsilon \in [0, 1/2] \), and let \( T: \mathcal{H} \rightarrow \mathcal{H} \) be an \( \alpha \)-averaged operator where \( T_i: \mathcal{H} \rightarrow \mathcal{H}_i \). Let \((\lambda_n)_{n \in \mathbb{N}} \) be in \([\epsilon, \alpha - 1 - \epsilon]\), set \( D = [0, 1]^m \setminus \{0\} \), let \( x_0 \) be an \( \mathcal{H} \)-valued random variable, and let \((\epsilon_n)_{n \in \mathbb{N}} \) be identically distributed \( D \)-valued random variables. Iterate

\[
(\forall i \in \{1, \ldots, m\}) \quad x_{i,n+1} = x_{i,n} + \epsilon_{i,n} \lambda_n (T_{i,n} x_n - x_{i,n}),
\]

(55)

In addition, assume that the following hold:

i) Fix \( T \neq \emptyset \).

ii) For every \( n \in \mathbb{N} \), \( \epsilon_n \) and \((x_0, \ldots, x_n) \) are mutually independent.

iii) \((\forall i \in \{1, \ldots, m\}) \quad \text{Prob} [\epsilon_{i,0} = 1] > 0.

Then \((x_n)_{n \in \mathbb{N}} \) converges a.s. to a Fix\( T \)-valued random variable.

Further results in this vein for iterations involving nonstationary compositions of averaged operators can be found in [97]. Mean square convergence results are also available under additional assumptions on the operators \((T_n)_{n \in \mathbb{N}} \) [99].

IV. FIXED POINT MODELING OF MONOTONE INCLUSIONS

A. Splitting sums of monotone operators

Our first basic model is that of finding a zero of the sum of two monotone operators. It will be seen to be central in understanding and solving data science problems in optimization form (see also Example 34 for a special case) and beyond.

\textbf{Problem 47} Let \( A: \mathcal{H} \rightarrow 2^\mathcal{H} \) and \( B: \mathcal{H} \rightarrow 2^\mathcal{H} \) be maximally monotone operators. The task is to

\[
\text{find } x \in \mathcal{H} \text{ such that } 0 \in Ax + Bx,
\]

(56)

under the assumption that a solution exists.
A classical method for solving Problem 47 is the Douglas-Rachford algorithm, which was first proposed in [166] (see also [120]; the following relaxed version is from [80]).

Proposition 48 (Douglas-Rachford splitting) Let \((\lambda_n)_{n \in \mathbb{N}}\) be a 1/2-relaxation sequence, let \(\gamma \in [0, +\infty]\), and let \(y_0 \in \mathcal{H}\). Iterate

\[
\begin{align*}
  x_n &= J_{\gamma B} y_n \\
  z_n &= J_{\gamma A} (2x_n - y_n) \\
  y_{n+1} &= y_n + \lambda_n (z_n - x_n).
\end{align*}
\]

Then \((x_n)_{n \in \mathbb{N}}\) converges to a solution to Problem 47.

The Douglas-Rachford algorithm requires the ability to evaluate two resolvents at each iteration. If one of the operators is single-valued and Lipschitzian, it can be applied explicitly, hence requiring only one resolvent evaluation per iteration. The resulting algorithm, proposed by Tseng [221], is often called the forward-backward-forward splitting algorithm since it involves two explicit (forward) steps using \(B\) and one implicit (backward) step using \(A\).

Proposition 49 (Tseng splitting) In Problem 47, assume that \(B\) is \(\delta\)-Lipschitzian for some \(\delta \in [0, +\infty]\). Let \(x_0 \in \mathcal{H}\), let \(\varepsilon \in [0, 1/(\delta + 1)]\), and \((\gamma_n)_{n \in \mathbb{N}}\) be in \([\varepsilon, (1 - \varepsilon)/\delta]\), and iterate

\[
\begin{align*}
  y_n &= x_n - \gamma_n B x_n \\
  z_n &= J_{\gamma A} y_n \\
  r_n &= z_n - \gamma_n B z_n \\
  x_{n+1} &= x_n - y_n + r_n.
\end{align*}
\]

Then \((x_n)_{n \in \mathbb{N}}\) converges to a solution to Problem 47.

As noted in Section II-C, if \(B\) is cocoercive, then it is Lipschitzian, and Proposition 49 is applicable. However, in this case it is possible to devise an algorithm which requires only one application of \(B\) per iteration, as opposed to two in (58). To see this, let \(\gamma_n \in [0, 2\beta]\) and \(x_n \in \mathcal{H}\). Then it follows at once from (36) that \(x\) solves Problem 47 \(\Leftrightarrow -\gamma_n B x \in \gamma_n A x \Leftrightarrow (x - \gamma_n B x) - x \in \gamma_n A x \Leftrightarrow x = J_{\gamma A}(x - \gamma_n B x) \Leftrightarrow x \in \text{Fix}(T_{1,n} \circ T_{2,n})\), where \(T_{1,n} = J_{\gamma A}\) and \(T_{2,n} = \text{Id} - \gamma_n B\). As seen in Theorem 32, \(T_{1,n}\) is 1/2-averaged. On the other hand, we derive from Proposition 13 that, if \(\alpha_{2,n} = \gamma_n/(2\beta)\), then \(T_{2,n}\) is \(\alpha_{2,n}\)-averaged. With these considerations, we invoke Theorem 39 to obtain the following algorithm, which goes back to [171].

Proposition 50 (forward-backward splitting [106]) Suppose that, in Problem 47, \(B\) is \(\beta\)-cocoercive for some \(\beta \in [0, +\infty]\). Let \(\varepsilon \in [0, \min\{1/2, \beta\}]\), let \(x_0 \in \mathcal{H}\), and let \((\gamma_n)_{n \in \mathbb{N}}\) be in \([\varepsilon, 2\beta/(1 + \varepsilon)]\). Let

\[
(\forall n \in \mathbb{N}) \quad \lambda_n \in [\varepsilon, (1 - \varepsilon)/(2 + \varepsilon - \gamma_n/(2\beta))].
\]

Iterate

\[
\begin{align*}
  u_n &= x_n - \gamma_n B x_n \\
  x_{n+1} &= x_n + \lambda_n (J_{\gamma A} u_n - x_n).
\end{align*}
\]

Then \((x_n)_{n \in \mathbb{N}}\) converges to a solution to Problem 47.

We now turn our attention to a more structured version of Problem 47, which includes an additional Lipschitzian monotone operator.

Problem 51 Let \(A : \mathcal{H} \to 2^\mathcal{H}\) and \(B : \mathcal{H} \to 2^\mathcal{H}\) be maximally monotone operators, let \(\delta \in [0, +\infty]\), and let \(C : \mathcal{H} \to \mathcal{H}\) be monotone and \(\delta\)-Lipschitzian. The task is to

\[
\text{find } x \in \mathcal{H} \text{ such that } 0 \in Ax + Bx + Cx,
\]

under the assumption that a solution exists.

The following approach provides also a dual solution.

Proposition 52 (splitting three operators I [96]) Consider Problem 51 and let \(\varepsilon \in [0, 1/(2 + \delta)]\). Let \((\gamma_n)_{n \in \mathbb{N}}\) be in \([\varepsilon, (1 - \varepsilon)/(1 + \delta)]\), let \(x_0 \in \mathcal{H}\), and let \(u_0 \in \mathcal{H}\). Iterate

\[
\begin{align*}
  y_n &= x_n - \gamma_n (Cx_n + u_n) \\
  p_n &= J_{\gamma_n A} y_n \\
  q_n &= u_n + \gamma_n (x_n - J_B y_n) \\
  x_{n+1} &= x_n - y_n + p_n - \gamma_n (Cp_n + q_n) \\
  u_{n+1} &= q_n + \gamma_n (p_n - x_n).
\end{align*}
\]

Then \((x_n)_{n \in \mathbb{N}}\) converges to a solution to Problem 51 and \((u_n)_{n \in \mathbb{N}}\) converges to a solution to the dual problem, i.e.,

\[
0 \in -(A + C)^{-1} u + B^{-1} u.
\]

When \(C\) is \(\beta\)-cocoercive in Problem 51, we can take \(\delta = 1/\beta\). In this setting, an alternative algorithm is obtained as follows. Let us fix \(\gamma \in [0, +\infty]\) and define

\[
T = J_{\gamma A} \circ (2J_{\gamma B} - \text{Id} - \gamma C \circ J_{\gamma B}) + \text{Id} - J_{\gamma B}.
\]

By setting \(T_1 = J_{\gamma A}\), \(T_2 = J_{\gamma B}\), and \(T_3 = \text{Id} - \gamma C\) in Proposition 20, we deduce from Proposition 13 that, if \(\gamma \in [0, 2\beta]\) and \(\alpha = 2\beta/(4\beta - \gamma)\), then \(T\) is \(\alpha\)-averaged. Now take \(y \in \mathcal{H}\) and set \(x = J_{\gamma B} y\), hence \(y - x \in \gamma B x\) by (36). Then \(y \in \text{Fix} T \Leftrightarrow J_{\gamma A}(2x - y - \gamma Cx) + y - x = y \Leftrightarrow J_{\gamma A}(2x - y - \gamma Cx) = x \Leftrightarrow x = x - y - \gamma Cx \in \gamma A x\) by (36). Thus, \(0 = (x - y) + (y - x) \in (\gamma A x + Bx + Cx)\), which shows that \(x\) solves Problem 51. Altogether, since \(y\) can be constructed via Theorem 37, we obtain the following convergence result.

Proposition 53 (splitting three operators II [113]) In Problem 51, assume that \(C\) is \(\beta\)-cocoercive for some \(\beta \in [0, +\infty]\). Let \(\gamma \in [0, 2\beta]\) and set \(\alpha = 2\beta/(4\beta - \gamma)\). Furthermore, let \((\lambda_n)_{n \in \mathbb{N}}\) be an \(\alpha\)-relaxation sequence and let \(y_0 \in \mathcal{H}\). Iterate

\[
\begin{align*}
  x_n &= J_{\gamma B} y_n \\
  r_n &= y_n + \gamma C x_n \\
  z_n &= J_{\gamma A} (2x_n - r_n) \\
  y_{n+1} &= y_n + \lambda_n (z_n - x_n).
\end{align*}
\]

Then \((x_n)_{n \in \mathbb{N}}\) converges to a solution to Problem 51.

Remark 54
i) Work closely related to Proposition 53 can be found in [38], [44], [190]. See also [189], which provides further developments and a discussion of [38], [113], [190].

ii) Unlike algorithm (62), (64) imposes constant proximal parameters and requires the cocoercivity of $C$, but it involves only one application of $C$ per iteration. An extension of (64) appears in [231] in the context of minimization problems.

B. Splitting sums of composite monotone operators

The monotone inclusion problems of Section IV-A are instantiations of the following formulation, which involves an arbitrary number of maximally monotone operators and compositions with linear operators.

**Problem 55** Let $\delta \in [0, +\infty]$ and let $A: H \rightarrow 2^H$ be maximally monotone. For every $k \in \{1, \ldots, q\}$, let $B_k: G_k \rightarrow 2^{G_k}$ be maximally monotone, let $0 \neq L_k: H \rightarrow G_k$ be linear, and let $C_k: G_k \rightarrow G_k$ be monotone and $\delta$-Lipschitzian. The task is to

$$
\text{find } x \in H \text{ such that } 0 \in Ax + \sum_{k=1}^{q} L_k^*((B_k + C_k)(L_kx)),
$$

under the assumption that a solution exists.

In the context of Problem 55, the principle of a splitting algorithm is to involve all the operators individually. In the case of a set-valued operator $A$ or $B_k$, this means using the associated resolvent, whereas in the case of a single-valued operator $C_k$ or $L_k$, a direct application should be considered. An immediate difficulty one faces with (65) is that it involves many set-valued operators. However, since inclusion is a binary relation, for reasons discussed in [41], [83] and analyzed in more depth in [200], it is not possible to deal with more than two such operators. To circumvent this fundamental limitation, a strategy is to rephrase Problem 55 as a problem involving at most two set-valued operators in a larger space. This strategy finds its root in convex feasibility problems [186] and it was first adapted to the problem of finding a zero of the sum of $m$ operators in [136], [208]. In [41], it was used to deal with the presence of linear operators (see in particular Example 34), with further developments in [33], [34], [85], [96], [226]. In the same spirit, let us reformulate Problem 55 by introducing

$$
\begin{align*}
L: H &\rightarrow G: x \mapsto (L_1x, \ldots, L_qx) \\
B: G &\rightarrow 2^G: (y_k)_{1 \leq k \leq q} \mapsto \bigcup_{k=1}^{q} B_ky_k \\
C: G &\rightarrow G: (y_k)_{1 \leq k \leq q} \mapsto \bigcup_{k=1}^{q} C_ky_k' \\
V &\text{range } L.
\end{align*}
$$

(66)

Note that $L$ is linear, $B$ is maximally monotone, and $C$ is monotone and $\delta$-Lipschitzian. In addition, the inclusion (65) can be rewritten more concisely as

$$
\text{find } x \in H \text{ such that } 0 \in Ax + L^*((B + C)(Lx)).
$$

(67)

In particular, suppose that $A = 0$. Then, upon setting $y = Lx \in V$, we obtain the existence of a point $u \in (B + C)y$ in $\ker L^* = V^\perp$. In other words,

$$
0 \in Ny + By + Cy.
$$

(68)

Solving this inclusion is equivalent to solving a problem similar to Problem 51, formulated in $G$. Thus, applying Proposition 53 to (68) leads to the following result.

**Proposition 56** In Problem 55, suppose that $A = 0$, that the operators $(B_k)_{1 \leq k \leq q}$ are $\beta$-cocoercive for some $\beta \in [0, +\infty]$, and that $Q = \sum_{k=1}^{q} L_k^* L_k$ is invertible. Let $\gamma \in [0, 2\beta]$, set $\alpha = 2\beta/(4\beta - \gamma)$, and let $(\lambda_n)_{n \in \mathbb{N}}$ be an $\alpha$-relaxation sequence. Further, let $y_0 \in G$, set $s_0 = Q^{-1}\left(\sum_{k=1}^{q} L_k^* y_{0,k}\right)$, and iterate

$$
\begin{align*}
\text{for } n = 0, 1, \ldots, \\
&\quad \text{for } k = 1, \ldots, q \\
&\quad \quad p_{n,k} = J_{\gamma B_k} y_{n,k} \\
&\quad \quad x_n = Q^{-1}\left(\sum_{k=1}^{q} L_k^* p_{n,k}\right) \\
&\quad \quad \gamma_n = Q^{-1}\left(\sum_{k=1}^{q} L_k^* C_k p_{n,k}\right) \\
&\quad \quad z_n = x_n - s_n - \gamma_n \epsilon_n \\
&\quad \quad \text{for } k = 1, \ldots, q \\
&\quad \quad s_{n+1,k} = s_n + \lambda_n z_n.
\end{align*}
$$

(69)

Then $(x_n)_{n \in \mathbb{N}}$ converges to a solution to (65).

A strategy for handling Problem 55 in its general setting consists of introducing an auxiliary variable $v \in B(Lx)$ in (67), which can then be rewritten as

$$
\begin{align*}
0 &\in Ax + L^* v + L^* (C(Lx)) \\
0 &\in -Lx + B^{-1} v.
\end{align*}
$$

(70)

This results in an instantiation of Problem 47 in $K = H \times G$ involving the maximally monotone operators

$$
\begin{align*}
A: K &\rightarrow 2K: (x, v) \mapsto \begin{bmatrix} A & 0 \\
0 & B^{-1} \end{bmatrix} [x, v] \\
C: K &\rightarrow K: (x, v) \mapsto \begin{bmatrix} L^* C L & L^* \\
-L & 0 \end{bmatrix} [x, v].
\end{align*}
$$

(71)

We observe that, in $K$, $B_1$ is Lipschitzian with constant $\chi = \|L\|(1 + \delta\|L\|)$. By applying Proposition 49 to (70), we obtain the following algorithm.

**Proposition 57** (96) Consider Problem 55. Set

$$
\chi = \sqrt{\sum_{k=1}^{q} \|L_k\|^2 (1 + \delta \sqrt{\sum_{k=1}^{q} \|L_k\|^2})}.
$$

(72)
Let $x_0 \in \mathcal{H}$, let $v_0 \in \mathcal{G}$, let $\varepsilon \in ]0, 1/(\chi + 1)[$, let $(\gamma_n)_{n \in \mathbb{N}}$ be in $[\varepsilon, (1 - \varepsilon)/\chi]$, and iterate

\[
\begin{align*}
&\text{for } n = 0, 1, \ldots, \\
&\quad u_n = x_n - \gamma_n \sum_{k=1}^q L_k^*(C_k(L_k x_n) + v_{n,k}) \\
&\quad p_n = J_{\gamma_n A} u_n \\
&\quad \text{for } k = 1, \ldots, q \\
&\quad y_{n,k} = v_{n,k} + \gamma_n L_k x_n \\
&\quad z_{n,k} = y_{n,k} - \gamma_n J_{\sigma^{-1} B_k} (y_{n,k}/\gamma_n) \\
&\quad s_{n,k} = z_{n,k} + \gamma_n L_k p_n \\
&\quad v_{n+1,k} = v_{n,k} - y_{n,k} + s_{n,k} \\
&\quad r_n = p_n - \gamma_n \sum_{k=1}^q L_k^*(C_k(L_k p_n) + z_{n,k}) \\
&\quad x_{n+1} = x_n - u_n + r_n.
\end{align*}
\]

Then $(x_n)_{n \in \mathbb{N}}$ converges to a solution to Problem 55.

An alternative solution consists of reformulating (70) in the form of Problem 47 with the maximally monotone operators

\[
\begin{align*}
A_2 \colon \mathcal{K} \to 2\mathcal{K} : (x, v) &\mapsto \begin{bmatrix} A & L^* \\ -L & B \end{bmatrix} x + v \\
B_2 \colon \mathcal{K} \to \mathcal{K} : (x, v) &\mapsto \begin{bmatrix} L^* \circ C \circ L \\ 0 \\ 0 \\ 0 \end{bmatrix} x + v
\end{align*}
\]

(74)

Instead of working directly with these operators, it may be judicious to use preconditioned versions $V \circ A_2$ and $V \circ B_2$, where $V : \mathcal{K} \to \mathcal{K}$ is a self-adjoint strictly positive linear operator. If $\mathcal{K}$ is renormed with

\[\| \cdot \|_{V} : (x, v) \mapsto \sqrt{\langle (x, v) \mid V^{-1} (x, v) \rangle},\]

(75)

then $V \circ A_2$ is maximally monotone in the renormed space and, if $C$ is cocoercive in $\mathcal{G}$, then $V \circ B_2$ is cocoercive in the renormed space. Thus, setting

\[V = \begin{bmatrix} W & 0 \\ 0 & (\sigma^{-1} \text{Id} - L \circ W \circ L^*)^{-1} \end{bmatrix},\]

(76)

where $W : \mathcal{H} \to \mathcal{H}$, and applying Proposition 50 in this context yields the following result (see [85]).

\[\text{Proposition 58} \quad \text{Suppose that, in Problem 55, } A = 0 \text{ and } (C_k)_{1 \leq k \leq q} \text{ are } \beta\text{-cocoercive for some } \beta \in ]0, +\infty[. \text{ Let } W : \mathcal{H} \to \mathcal{H} \text{ be a self-adjoint strictly positive linear operator and let } \sigma \in ]0, +\infty[ \text{ be such that } \kappa = \| L \circ W \circ L^* \| < \min\{1/\sigma, 2\beta\}. \text{ Let } \varepsilon \in ]0, \min\{1/2, \beta/\kappa\}[, \text{ let } x_0 \in \mathcal{H}, \text{ and let } v_0 \in \mathcal{G}. \text{ For every } n \in \mathbb{N}, \text{ let}
\]

\[\lambda_n \in [\varepsilon, (1 - \varepsilon)(2 + \varepsilon - \kappa/2\beta)].\]

(77)

\[\text{Iterate for } n = 0, 1, \ldots
\]

\[\text{for } k = 1, \ldots, q
\]

\[s_{n,k} = C_k(L_k x_n)
\]

\[z_n = x_n - W(\sum_{k=1}^q L_k(s_{n,k} + v_{n,k}))
\]

\[\text{for } k = 1, \ldots, q
\]

\[w_{n,k} = v_{n,k} + \sigma L_k z_n
\]

\[y_{n,k} = w_{n,k} - \sigma J_{\sigma^{-1} B_k}(w_{n,k}/\sigma)
\]

\[v_{n+1,k} = v_{n,k} - y_{n,k} + \lambda_n(y_{n,k} - v_{n,k})
\]

\[u_n = x_n - W(\sum_{k=1}^q L_k^*(s_{n,k} + y_{n,k}))
\]

\[x_{n+1} = x_n + \lambda_n(u_n - x_n).
\]

Then $(x_n)_{n \in \mathbb{N}}$ converges to a solution to Problem 55.

\[\text{Other choices of the metric operator } V \text{ are possible, which lead to different primal-dual algorithms [102], [107], [157], [226]. An advantage of (73) and (78) over (69) is that the first two do not require the inversion of linear operators.}\]

\[\text{C. Block-iterative algorithms}\]

\[\text{As will be seen in Problems 84 and 86, systems of inclusions arising in multivariate optimization problems (they will also be present in Nash equilibria; see, e.g., (153) and (183)). We now focus on general systems of inclusions involving maximally monotone operators as well as linear operators coupling the variables.}\]

\[\text{Problem 59} \quad \text{For every } i \in I = \{1, \ldots, m\} \text{ and } k \in K = \{1, \ldots, q\}, \text{ let } A_i : \mathcal{H}_i \to 2^{\mathcal{H}_i}, \text{ and } B_k : \mathcal{G}_k \to 2^{\mathcal{G}_k} \text{ be maximally monotone, and let } L_{k,i} : \mathcal{H}_i \to \mathcal{G}_k \text{ be linear. The task is to find}
\]

\[\bar{x}_1 \in \mathcal{H}_1, \ldots, t_m \in \mathcal{H}_m \text{ such that } (\forall i \in I)
\]

\[\begin{align*}
0 &\in A_i \bar{x}_i + \sum_{k \in K} L_{k,i}^*(B_k\left(\sum_{j \in I} L_{j,k}\bar{x}_j\right))
\end{align*}
\]

(79)

under the assumption that the Kuhn-Tucker set

\[Z = \left\{ (\bar{x}, v) \in \mathcal{H} \times \mathcal{G} \mid (\forall i \in I) - \sum_{k \in K} L_{k,i}^* v_k \in A_i \bar{x}_i \right\}
\]

(80)

\[\text{is nonempty.}\]

\[\text{We can regard } m \text{ as the number of coordinates of the solution vector } \bar{x} = (\bar{x}_1)_{1 \leq i \leq m}. \text{ In large-scale applications, } m \text{ can be sizable and so can the number of terms } q, \text{ which is often associated with the number of observations. We have already discussed in Sections III-C and III-E techniques in which not all the indices } i \text{ or } k \text{ need to be activated at a given iteration under certain hypotheses on the structure of the problem. Below, we describe a block-iterative method proposed in [87] which allows for partial activation of both the families and } (A_i)_{1 \leq i \leq m} \text{ and } (B_k)_{1 \leq k \leq q}, \text{ together with individual, iteration-dependent proximal parameters for each operator. The method displays an unprecedented level of flexibility and it does not require the inversion of linear operators or knowledge of their norms.}\]

\[\text{The principle of the algorithm is as follows. Denote by } I_n \subset I \text{ and } K_n \subset K \text{ the blocks of indices of operators to be updated at iteration } n. \text{ We impose the mild condition that there exist } M \in \mathbb{N} \text{ such that each operator index } i \text{ and } k \text{ is used at least once within any } M \text{ consecutive iterations, i.e., for every } n \in \mathbb{N},
\]

\[\bigcup_{j=n}^{n+M-1} I_j = \{1, \ldots, m\} \text{ and } \bigcup_{j=n}^{n+M-1} K_j = \{1, \ldots, q\}.\]

(81)

For each $i \in I_n$ and $k \in K_n$, we select points $(a_{i,n}, b_{i,n}^k) \in \text{gra } A_i$ and $(b_{k,n}, b_{k,n}^k) \in \text{gra } B_k$ and use them to construct
a closed half-space \( H_n \subset \mathcal{H} \times \mathcal{G} \) which contains \( Z \). The primal variable \( x_n \) and the dual variable \( v_n \) are updated as \((x_{n+1}, v_{n+1}) = \text{proj}_{H_n}(x_n, v_n)\). The resulting algorithm can also be implemented with relaxations and in an asynchronous fashion \([87]\). For simplicity, we present the unrelaxed synchronous version.

**Proposition 60 ([87])** Consider the setting of Problem 59. Take sequences \((I_n)_{n \in \mathbb{N}}\) in \( I \) and \((K_n)_{n \in \mathbb{N}}\) in \( K \) satisfying (81), with \( I_0 = I \) and \( K_0 = K \). Let \( \varepsilon \in [0,1] \) and, for every \( i \in I \) and every \( k \in K \), let \((\gamma_{i,n})_{n \in \mathbb{N}}\) and \((\mu_{k,n})_{n \in \mathbb{N}}\) be sequences in \([\varepsilon, 1/\varepsilon]\). Let \( x_0 \in \mathcal{H} \), let \( v_0 \in \mathcal{G} \), and iterate

\[
\text{for } n = 0, 1, \ldots \text{ }
\begin{align*}
& \text{for every } i \in I_n \\
& \quad l_{i,n}^* = \sum_{k \in K} L_{k,i}^* v_{k,n} \\
& \quad a_{i,n} = J_{\gamma_{i,n}} \left( x_{i,n} - l_{i,n}^* \right) \\
& \quad a_{i,n}^* = \gamma_{i,n}^{-1} \left( x_{i,n} - a_{i,n} \right) - l_{i,n}^* \\
& \text{for every } i \in I \text{ and } k \in K_n \\
& \quad b_{k,n} = J_{\mu_{k,n}} \left( x_{k,n} + \mu_{k,n} v_{k,n} \right) \\
& \quad b_{k,n}^* = v_{k,n} + \mu_{k,n} \left( l_{k,n} - b_{k,n} \right)
\end{align*}
\]

Then \((x_n)_{n \in \mathbb{N}}\) converges to a solution to Problem 59.

Recent developments on splitting algorithms for Problem 59 as well as variants and extensions thereof can be found in \([45], [46], [132], [153]\).

V. FIXED POINT MODELING OF MINIMIZATION PROBLEMS

We present key applications of fixed point models in convex optimization.

**A. Convex feasibility problems**

The most basic convex optimization problem is the convex feasibility problem, which asks for compliance with a finite number of convex constraints the object of interest is known to satisfy. This approach was formalized by Youla \([236], [238]\) in signal recovery and it has enjoyed a broad success \([75], [77], [144], [210], [216], [220]\).

**Problem 61** Let \((C_i)_{1 \leq i \leq m}\) be nonempty closed convex subsets of \( \mathcal{H} \). The task is to

\[
\text{find } x \in \bigcap_{i=1}^{m} C_i.
\]

Suppose that Problem 61 has a solution and that each set \( C_i \) is modeled as the fixed point set of an \( \alpha_i \)-averaged operator \( T_i: \mathcal{H} \to \mathcal{H} \) some \( \alpha_i \in [0,1] \). Then, applying Theorem 37 with \( T = T_1 \circ \cdots \circ T_m \) (which is averaged by Proposition 18) and \( \lambda_n = 1 \) for every \( n \in \mathbb{N} \), we obtain that the sequence \((x_n)_{n \in \mathbb{N}}\) constructed via the iteration

\[
(\forall n \in \mathbb{N}) \quad x_{n+1} = (T_1 \circ \cdots \circ T_m) x_n
\]

converges to a fixed point \( x \) of \( T_1 \circ \cdots \circ T_m \). However, in view of Proposition 26, \( x \) is a solution to (83). In particular, if each \( T_i \) is the projection operator onto \( C_i \) (which was seen to be 1/2-averaged), we obtain the classical POCS (Projection Onto Convex Sets) algorithm \([122]\)

\[
(\forall n \in \mathbb{N}) \quad x_{n+1} = \left( \text{proj}_{C_1} \circ \cdots \circ \text{proj}_{C_m} \right) x_n
\]

popularized in \([238]\) and which goes back to \([154]\) in the case of affine hyperplanes. In this algorithm, the projection operators are used sequentially. Another basic projection method for solving (83) is the barycentric projection algorithm

\[
(\forall n \in \mathbb{N}) \quad x_{n+1} = \frac{1}{m} \sum_{i=1}^{m} \text{proj}_{C_i} x_n,
\]

which uses the projections simultaneously and goes back to \([73]\) in the case of affine hyperplanes. Its convergence is proved by applying Theorem 37 to \( T = m^{-1} \sum_{i=1}^{m} \text{proj}_{C_i} \) which is 1/2-averaged by Example 17. More general fixed point methods are discussed in \([15], [20], [78], [156]\).

**B. Split feasibility problems**

The so-called **split feasibility problem** is just a convex feasibility problem involving a linear operator \([49], [56], [57]\).

**Problem 62** Let \( C \subset \mathcal{H} \) and \( D \subset \mathcal{G} \) be closed convex sets and let \( 0 \neq L: \mathcal{H} \to \mathcal{G} \) be linear. The task is to

\[
\text{find } x \in C \text{ such that } Lx \in D,
\]

under the assumption that a solution exists.

In principle, we can reduce this problem to a 2-set version of (85) with \( C_1 = C \) and \( C_2 = L^{-1}(D) \). However the projection onto \( C_2 \) is usually not tractable, which makes projection algorithms such as (85) or (86) not implementable. To work around this difficulty, let us define \( T_1 = \text{proj}_C \) and
Hence, \( T_2 = \text{Id} - \gamma G_2 \), where \( G_2 = L^* \circ (\text{Id} - \text{proj}_D) \circ L \) and \( \gamma \in [0, +\infty[. \) Then \( (\forall x \in H) \) \( Lx \in D \iff G_2x = 0 \).\(^1\) Hence, \[
\text{Fix} \ T_1 = C \quad \text{and} \quad \text{Fix} \ T_2 = \{x \in H \mid Lx \in D\}. \tag{88}
\]
Furthermore, \( T_1 \) is \( \alpha_1 \)-averaged with \( \alpha_1 = 1/2 \). In addition, \( \text{Id} - \text{proj}_D \) is firmly nonexpansive by (24) and therefore \( 1 \)-cocoercive. It follows from Proposition 21 that \( G_2 \) is cocoercive with constant \( 1/\|L\|^2 \). Now let \( \gamma \in [0, 2/\|L\|^2] \) and set \( \alpha_2 = \gamma/\|L\|^2/2 \). Then Proposition 13 asserts that \( \text{Id} - \gamma G_2 \) is \( \alpha_2 \)-averaged. Altogether, we deduce from Example 19 that \( T_1 \circ T_2 \) is \( \alpha \)-averaged. Now let \((\lambda_n)_{n \in \mathbb{N}}\) be an \( \alpha \)-relaxation sequence. According to Theorem 37 and Proposition 26, the sequence produced by the iterations \[
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \lambda_n \cdot (\text{proj}_C(x_n - \gamma L^* (Lx_n - \text{proj}_D(Lx_n)))) - x_n
\]
converges to a point in \( \text{Fix} \ T_1 \cap \text{Fix} \ T_2 \), i.e., in view of (88), to a solution to Problem 62. In particular, if we take \( \lambda_n = 1 \), the update rule in (89) becomes \[
 x_{n+1} = \text{proj}_C \left( x_n - \gamma L^* (Lx_n - \text{proj}_D(Lx_n)) \right). \tag{90}
\]

C. Convex minimization

We deduce from Fermat’s rule (Theorem 3) and Proposition 6 the fact that a differentiable convex function \( f : H \to \mathbb{R} \) admits \( x \in H \) as a minimizer if and only if \( \nabla f(x) = 0 \). Now let \( \gamma \in [0, +\infty[ \). Then this property is equivalent to \( x = x - \gamma \nabla f(x) \), which shows that \[
\text{Argmin} f = \text{Fix} \ T, \quad \text{where} \quad T = \text{Id} - \gamma \nabla f. \tag{91}
\]
If we add the assumption that \( \nabla f = \delta \)-Lipschitzian, then it is \( 1/\delta \)-cocoercive by Proposition 14. Hence, if \( 0 < \gamma < 2/\delta \), it follows from Proposition 13, that \( T \) in (91) is \( \alpha \)-averaged with \( \alpha = \gamma\delta/2 \). We then derive from Theorem 37 the convergence of the steepest-descent method.

Proposition 63 (steepest-descent) Let \( f : H \to \mathbb{R} \) be a differentiable convex function such that \( \text{Argmin} f \neq \emptyset \) and \( \nabla f \) is \( \delta \)-Lipschitzian for some \( \delta \in [0, +\infty[ \). Let \( \gamma \in [0, 2/\delta] \), let \((\lambda_n)_{n \in \mathbb{N}}\) be a \( \gamma\delta/2 \)-relaxation sequence, and let \( x_0 \in H \). Set \[
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n - \gamma \lambda_n \nabla f(x_n).
\]
Then \((x_n)_{n \in \mathbb{N}}\) converges to a point in \( \text{Argmin} f \).

Now, let us remove the smoothness assumption by considering a general function \( f \in \Gamma_0(H) \). Then it is clear from (9) that \( (\forall x \in H) \) \( x = \text{prox}_f x \iff (\forall y \in H) \) \( f(x) \leq f(y) \). In other words, we obtain the fixed point characterization \[
\text{Argmin} f = \text{Fix} \ T, \quad \text{where} \quad T = \text{prox}_f. \tag{93}
\]

\(^1\) Set \( T = \text{Id} - \text{proj}_D \) and fix \( x \in H \) such that \( Lx \in D \). Then \( T(Lx) = 0 \) and thus \( G_2x = 0 \). Conversely, take \( x \in H \) such that \( G_2x = 0 \). Since \( T \) is firmly nonexpansive by Example 11, applying (18) with \( \beta = 1 \) yields \( 0 = (0-x-x-x) = (G_2x - G_2x - x - x) = (L^*(T(Lx) - T(Lx)) \mid x - x) = (T(Lx) - T(Lx)) \mid Lx - Lx \geq \|T(Lx) - T(Lx)\|^2 = \|T(Lx)\|^2 \). So \( T(Lx) = 0 \) and therefore \( Lx = \text{proj}_D(Lx) \in D \).

In turn, since \( \text{prox}_f \) is firmly nonexpansive (see Example 11), we derive at once from Theorem 37 the convergence of the proximal point algorithm.

Proposition 64 (proximal point algorithm) Let \( f \in \Gamma_0(H) \) be such that \( \text{Argmin} f \neq \emptyset \). Let \( \gamma \in [0, +\infty[ \), let \((\lambda_n)_{n \in \mathbb{N}}\) be a \( 1/2 \)-relaxation sequence, and let \( x_0 \in H \). Set \[
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \lambda_n (\text{prox}_f x_n - x_n). \tag{94}
\]
Then \((x_n)_{n \in \mathbb{N}}\) converges to a point in \( \text{Argmin} f \).

Remark 65 We can interpret the barycentric projection algorithm (86) as an unrelaxed instance of the proximal point algorithm (94) with \( \gamma = 1 \) by applying Remark 22 with \( q = m \) and, for every \( k \in \{1, \ldots, q\} \), \( \omega_k = 1/q, G_k = H, L_k = \text{Id}, \) and \( g_k = t_{C_k} \).

A more versatile minimization model is the following instance of the formulation discussed in Proposition 7.

Problem 66 Let \( f \in \Gamma_0(H) \) and \( g \in \Gamma_0(H) \) be such that \( (\text{ri dom} f) \cap (\text{ri dom} g) \neq \emptyset \) and \( \lim_{\|x\| \to +\infty} f(x) + g(x) = +\infty \). The task is to minimize \[
f(x) + g(x). \tag{95}
\]

It follows from Proposition 7i) that Problem 66 has a solution and from Proposition 7ii) that it is equivalent to Problem 51 with \( A = \partial f \) and \( B = \partial g \). It then remains to appeal to Proposition 48 and Example 33 to obtain the following algorithm, which employs the proximity operators of \( f \) and \( g \) separately.

Proposition 67 (Douglas-Rachford splitting) Let \((\lambda_n)_{n \in \mathbb{N}}\) be a \( 1/2 \)-relaxation sequence, let \( \gamma \in [0, +\infty[ \), and let \( y_n \in H \). Iterate \[
\begin{align*}
x_n &= \text{prox}_{\gamma f} y_n \\
y_n &= \text{prox}_{\gamma f} (2x_n - y_n) \\
y_{n+1} &= y_n + \lambda_n (z_n - x_n).
\end{align*}
\]
Then \((x_n)_{n \in \mathbb{N}}\) converges to a solution to Problem 66.

The Douglas-Rachford algorithm was first employed in signal and image processing in [94] and it has since been applied to various problems, e.g., [68], [165], [184], [211], [239]. For a recent application to joint scale/regression estimation in statistical data analysis involving several product space reformulations, see [92]. We now present two applications to matrix optimization problems. Along the same lines, the Douglas-Rachford algorithm is also used in tensor decompositions [129].

Example 68 Let \( H \) be the space of \( N \times N \) real symmetric matrices equipped with the Frobenius norm. We denote by \( \xi_{i,j} \) the \( i,j \)th component of \( X \in H \). Let \( O \in H \). The graphical lasso problem [127], [191] is to minimize \[
\min_{X \in H} f(X) + \ell(X) + \text{trace}(OX),
\]
where
where
\[ f(X) = \chi \sum_{i=1}^{N} \sum_{j=1}^{N} |x_{i,j}|, \quad \text{with } \chi \in [0, +\infty], \] (98)
amd
\[ \ell(X) = \begin{cases} -\ln \det X, & \text{if } X \text{ is positive definite;} \\ +\infty, & \text{otherwise.} \end{cases} \] (99)

Problem (97) arises in the estimation of a sparse precision (i.e., inverse covariance) matrix from an observed matrix \( O \) and it has found applications in graph processing. Since \( \ell \in \Gamma_0(\mathcal{H}) \) is a symmetric function of the eigenvalues of its arguments, by [19, Corollary 24.65], its proximity operator at \( X \) is obtained by performing an eigendecomposition
\[ [U, (\mu_i)_{1 \leq i \leq N}] = \text{eig}(X) \Leftrightarrow X = U \text{Diag}(\mu_1, \ldots, \mu_N)U^\top. \]
Here, given \( \gamma \in [0, +\infty) \), [19, Example 24.66] yields
\[ \text{prox}_\gamma X = U \text{Diag}((\text{prox}_{-\gamma \text{ln}} \mu_1, \ldots, \text{prox}_{-\gamma \text{ln}} \mu_N))U^\top, \] (100)

where \( \text{prox}_{-\gamma \ln} : x \mapsto (\chi + \sqrt{\chi^2 + 4xy})/2 \). Let \( (\lambda_n)_{n \in \mathbb{N}} \) be a 1/2-relaxation sequence, let \( \lambda \in [0, +\infty) \), and let \( Y_0 \in \mathcal{H} \). Upon setting \( g = \ell + (\cdot | O) \), the Douglas-Rachford algorithm of (96) for solving (97) becomes

for \( n = 0, 1, \ldots \)
\[ \begin{aligned}
& [U_n, (\mu_{i,n})_{1 \leq i \leq N}] = \text{eig}(Y_n - \gamma O) \\
& X_n = U_n \text{Diag}((\text{prox}_{-\gamma \text{ln}} \mu_1, \ldots, \text{prox}_{-\gamma \text{ln}} \mu_N))U_n^\top \\
& Z_n = \text{soft}_\chi(2X_n - Y_n) \\
& Y_{n+1} = Y_n + \lambda_n(Z_n - X_n),
\end{aligned} \] (101)

where \text{soft}_\chi denotes the soft-thresholding operator on \([-\chi, \chi]\) applied componentwise. Applications of (101) as well as variants with other choices of \( \ell \) and \( g \) are discussed in [25].

\[ \text{Example 69 (robust PCA)} \quad \text{Let } M \text{ and } N \text{ be integers such that } M \geq N > 0, \text{ and let } \mathcal{H} \text{ be the space of } N \times M \text{ real matrices equipped with the Frobenius norm. The robust Principal Component Analysis (PCA) problem} [52], [223] \text{ is to minimize} \]
\[ \min_{X \in \mathcal{H}, Y \in \mathcal{H}} ||Y||_{\text{nuc}} + \chi ||X||_1, \] (102)

where \( \| \cdot \|_1 \) is the \( \ell_1 \)-norm, \( \| \cdot \|_{\text{nuc}} \) is the nuclear norm, and \( \chi \in [0, +\infty] \). Let \( X = U \text{Diag}(\sigma_1, \ldots, \sigma_N)\) be the singular value decomposition of \( X \in \mathcal{H} \). Then \( ||X||_{\text{nuc}} = \sum_{i=1}^{N} \sigma_i \) and, by [19, Example 24.69],
\[ \text{prox}_{\chi ||X||_{\text{nuc}}} X = U \text{Diag}(\text{soft}_\chi \sigma_1, \ldots, \text{soft}_\chi \sigma_N)\] (103)

An implementation of the Douglas-Rachford algorithm in the product space \( \mathcal{H} \times \mathcal{H} \) to solve (102) is detailed in [19, Example 28.6].

By combining Propositions 50, 6, and 14, together with Example 33, we obtain the convergence of the forward-backward splitting algorithm for minimization. The broad potential of this algorithm in data science was evidenced in [103]. Inertial variants are presented in [22], [29], [60], [88].

\[ \text{Proposition 70 (forward-backward splitting)} \quad \text{Suppose that, in Problem 66, } g \text{ is differentiable everywhere and that its gradient is } \delta \text{-Lipschitzian for some } \delta \in [0, +\infty]. \text{ Let } \varepsilon \in [0, \min\{1/2, 1/\delta\}], \text{ let } x_0 \in \mathcal{H}, \text{ and let } (\gamma_n)_{n \in \mathbb{N}} \text{ be in } [\varepsilon, 2/(\delta(1 + \varepsilon))], \text{ and let}
\[ (\forall n \in \mathbb{N}) \quad \lambda_n \in [\varepsilon, (1 - \varepsilon)(2 + \varepsilon - \delta \gamma_n/2)]. \]
(104)

Iterate
\[ \begin{aligned}
& u_n = x_n - \gamma_n \nabla g(x_n) \\
& x_{n+1} = x_n + \lambda_n(\text{prox}_{\gamma_n} fu_n - x_n),
\end{aligned} \] (105)

Then \( (x_n)_{n \in \mathbb{N}} \text{ converges to a solution to Problem 66.} \]

**Example 71** Let \( M \) and \( N \) be integers such that \( M \geq N > 0 \), and let \( \mathcal{H} \) be the space of \( N \times M \) real-valued matrices equipped with the Frobenius norm. The task is to reconstruct a low-rank matrix given its projection \( O \) onto a vector space \( V \subset \mathcal{H} \). Let \( L = \text{proj}_V \). The problem is formulated as
\[ \min_{X \in \mathcal{H}} \frac{1}{2}||O - LX||^2 + \chi ||X||_{\text{nuc}} \] (106)

where \( \chi \in [0, +\infty] \). As seen in Example 69, the proximity operator of the nuclear norm has a closed form expression. In addition, \( g : X \mapsto ||O - LX||^2/2 \) is convex and its gradient
\[ \nabla g : X \mapsto L^*(LX - O) = LX - O \text{ is nonexpansive.} \]
Problem (106) can thus be solved by algorithm (105) where \( f = \chi || \cdot ||_{\text{nuc}} \) and \( \delta = 1 \). A particular case of (106) is the matrix completion problem [53], [54], where only some components of the sought matrix are observed. If \( \mathbb{K} \) denotes the set of indices of the unknown matrix components, we have
\[ V = \{ X \in \mathcal{H} | (\forall (i,j) \in \mathbb{K}) x_{i,j} = 0 \}. \]

**Example 72** Let \( X \) and \( W \) be mutually independent \( \mathbb{R}^N \)-valued random vectors. Assume that \( X \) is absolutely continuous and square-integrable, and that its probability density function is log-concave. Further, assume that \( W \) is Gaussian with zero-mean and covariance \( \sigma^2 I_N \), where \( \sigma \in [0, +\infty] \). Let \( Y = X + W \). For every \( y \in \mathbb{R}^N \), \( Q_y = E[X | Y = y] \) is the minimum mean square error (MMSE) denoiser for \( X \) given the observation \( y \). The properties of \( Q \) have been investigated in [139]. It can be shown that \( Q \) is the proximity operator of the conjugate of \( h = (1/\sigma^2 \log p)^* || \cdot ||^2/2 \in \Gamma_0(\mathbb{R}^N) \), where \( p \) is the density of \( Y \). Let \( g : \mathbb{R}^N \rightarrow \mathbb{R} \) be a differentiable convex function with a \( \delta \)-Lipschitzian gradient for some \( \delta \in [0, +\infty] \), and let \( \gamma \in [0, 2/\delta] \). The iteration
\[ (\forall n \in \mathbb{N}) \quad x_{n+1} = Q(x_n - \gamma \nabla g(x_n)) \] (107)

therefore turns out to be a special case of the forward-backward algorithm (105), where \( f = h^* / \gamma \) and \( (\forall n \in \mathbb{N}) \lambda_n = 1 \). This algorithm is studied in [229] from a different perspective.

The projection-gradient method goes back to the classical papers [135], [164]. A version can be obtained by setting \( f = \iota_C \) in Proposition 70, where \( C \) is the constraint set. Below, we describe the simpler formulation resulting from the application of Theorem 37 to \( T = \text{proj}_C \circ (I_d - \gamma \nabla g) \).
Example 73 (projection-gradient) Let $C$ be a nonempty closed convex subset of $\mathcal{H}$ and let $g : \mathcal{H} \to \mathbb{R}$ be a differentiable convex function, with a $\delta$-Lipschitzian gradient for some $\delta \in [0, +\infty]$. The task is to

\[
\begin{equation}
\text{minimize } g(x), \quad (108)
\end{equation}
\]

under the assumption that $\lim_{\|x\| \to +\infty} g(x) = +\infty$ or $C$ is bounded. Let $\gamma \in [0, 2/\delta]$ and set $\alpha = 2/(4 - \gamma \delta)$. Furthermore, let $(\lambda_n)_{n \in \mathbb{N}}$ be an $\alpha$-relaxation sequence and let $x_0 \in \mathcal{H}$. Iterate

\[
\begin{align}
\text{for } n = 0, 1, \ldots \\
y_n &= x_n - \gamma \nabla g(x_n) \\
x_{n+1} &= x_n + \lambda_n (\text{proj}_{C} y_n - x_n).
\end{align}
\]

Then $(x_n)_{n \in \mathbb{N}}$ converges to a solution to (108).

As a special case of Example 73, we obtain the convergence of the alternating projections algorithm [65], [164].

Example 74 (alternating projections) Let $C_1$ and $C_2$ be nonempty closed convex subsets of $\mathcal{H}$, one of which is bounded. Given $x_0 \in \mathcal{H}$, iterate

\[
(\forall n \in \mathbb{N}) \quad x_{n+1} = \text{proj}_{C_1} (\text{proj}_{C_2} x_n). \quad (110)
\]

Then $(x_n)_{n \in \mathbb{N}}$ converges to a solution to the constrained minimization problem

\[
\begin{equation}
\text{minimize } d_{C_2}(x), \quad (111)
\end{equation}
\]

This follows from Example 73 applied to $g = d_{C_2}^2/2$. Note that $\nabla g = \text{Id} - \text{proj}_{C_2}$ has Lipschitz constant $\delta = 1$ (see Example 5) and hence (110) is the instance of (109) obtained by setting $\gamma = 1$ and $(\forall n \in \mathbb{N}) \lambda_n = 1$ (see Example 10i).

The following version of Problem 66 involves $m$ smooth functions.

Problem 75 Let $(\omega_i)_{1 \leq i \leq m}$ be real numbers in $[0, 1]$ such that $\sum_{i=1}^m \omega_i = 1$. Let $f_0 \in \Gamma_0(\mathcal{H})$ and, for every $i \in \{1, \ldots, m\}$, let $\delta_i \in [0, +\infty]$ and let $f_i : \mathcal{H} \to \mathbb{R}$ be a differentiable convex function with a $\delta_i$-Lipschitzian gradient. Suppose that

\[
\lim_{\|x\| \to +\infty} f_0(x) + \sum_{i=1}^m \omega_i f_i(x) = +\infty. \quad (112)
\]

The task is to

\[
\begin{equation}
\text{minimize } x \in \mathcal{H} f_0(x) + \sum_{i=1}^m \omega_i f_i(x). \quad (113)
\end{equation}
\]

To solve Problem 75, an option is to apply Theorem 44 to obtain a forward-backward algorithm with block-updates.

Proposition 76 ([90]) Consider the setting of Problem 75. Let $(I_n)_{n \in \mathbb{N}}$ be a sequence of nonempty subsets of $\{1, \ldots, m\}$ such that (49) holds for some $M \in \mathbb{N} \setminus \{0\}$. Let $\gamma \in [0, 2/\max_{1 \leq i \leq m} \delta_i[, \ let x_0 \in \mathcal{H}$, let $(t_{i,-1})_{1 \leq i \leq m} \in \mathcal{H}^m$, and iterate

\[
\begin{align}
\text{for } n = 0, 1, \ldots & \\
& [\text{for every } i \in I_n] \\
& \quad t_{i,n} = x_n - \gamma \nabla f_i(x_n) \\
& \quad x_{n+1} = \text{prox}_{\alpha f_0} (\sum_{i=1}^m \omega_i t_{i,n}).
\end{align}
\]

Then the following hold:

i) Let $x$ be a solution to Problem 75 and let $i \in \{1, \ldots, m\}$. Then $\nabla f_i(x_n) \to \nabla f_i(x)$.

ii) $(x_n)_{n \in \mathbb{N}}$ converges to a solution to Problem 75.

iii) Suppose that, for some $i \in \{0, \ldots, m\}$, $f_i$ is strongly convex. Then $(x_n)_{n \in \mathbb{N}}$ converges linearly to the unique solution to Problem 75.

A method related to (114) is proposed in [173]; see also [175] for a special case. Here is a data analysis application.

Example 77 Let $(e_k)_{1 \leq k \leq N}$ be an orthonormal basis of $\mathcal{H}$ and, for every $k \in \{1, \ldots, N\}$, let $\psi_k \in \Gamma_0(\mathbb{R})$. For every $i \in \{1, \ldots, m\}$, let $0 \not= a_i \in \mathcal{H}$, let $\mu_i \in [0, +\infty]$, and let $\phi_i : \mathbb{R} \to [0, +\infty]$ be a differentiable convex function such that $\phi_i''$ is $\mu_i$-Lipschitzian. The task is to

\[
\begin{equation}
\text{minimize } x \in \mathcal{H} \sum_{k=1}^N \psi_k((x | e_k)) + \frac{1}{m} \sum_{i=1}^m \phi_i((x | a_i)). \quad (115)
\end{equation}
\]

As shown in [90], (115) is an instantiation of (113) and, given $\gamma \in [0, 2/\max_{1 \leq i \leq m} \mu_i |a_i|^2]$, and subsets $(I_n)_{n \in \mathbb{N}}$ of $\{1, \ldots, m\}$ such that (49) holds, it can be solved by (114), which becomes

\[
\begin{align}
& [\text{for every } i \in I_n] \\
& \quad t_{i,n} = x_n - \gamma \phi_i'((x_n | a_i)) a_i \\
& \quad x_{n+1} = \sum_{k=1}^N \omega_k t_{i,n} \\
& \quad y_{n+1} = \sum_{k=1}^N \text{prox}_{\alpha \phi_k} ((y_n | e_k)) e_k.
\end{align}
\]

A popular setting is obtained by choosing $\mathcal{H} = \mathbb{R}^N$ and $(e_k)_{1 \leq k \leq N}$ as the canonical basis, $\alpha \in [0, +\infty]$, and, for every $k \in \{1, \ldots, K\}$, $\psi_k = \alpha | \cdot |$. This reduces (115) to

\[
\begin{equation}
\text{minimize } \alpha \|x\|_1 + \sum_{i=1}^m \phi_i((x | a_i)). \quad (117)
\end{equation}
\]

Choosing, for every $i \in \{1, \ldots, m\}$, $\phi_i : t \mapsto |t - \eta_i|^2$ where $\eta_i \in \mathbb{R}$ models an observation, yields the lasso formulation, whereas choosing $\phi_i : t \mapsto \ln(1 + \exp(t)) - \eta_i t$, where $\eta_i \in (0, 1)$ models a label, yields the penalized logistic regression framework [142].

Next, we extend Problem 66 to a flexible composite minimization problem. See [34], [66], [67], [69], [70], [85], [89], [92], [174], [184], [185], [192] for concrete instantiations of this model in data science.
**Problem 78** Let $\delta \in [0, +\infty]$ and let $f \in \Gamma_0(\mathcal{H})$. For every $k \in \{1, \ldots, q\}$, let $g_k \in \Gamma_0(G_k)$, let $0 \neq L_k : \mathcal{H} \to G_k$ be linear, and let $h_k : G_k \to \mathbb{R}$ be a differentiable convex function, with a $\delta$-Lipschitz gradient. Suppose that
\[
\lim_{x \to +\infty} f(x) + \sum_{k=1}^{q} (g_k(L_kx) + h_k(L_kx)) = +\infty
\]
and that
\[
(\exists z \in \text{ri dom } f)(\forall k \in \{1, \ldots, q\}) \quad L_k z \in \text{ri dom } g_k.
\]
Then, given $y_0 \in \mathcal{G}$ and $z_0 \in \mathcal{G}$, the alternating-direction method of multipliers (ADMM) constructs a sequence $(x_n)_{n \in \mathbb{N}}$ that converges to a solution to (122) [120] via the iterations [35], [128], [133]
\[
\begin{align*}
\begin{cases}
x_n = \text{prox}_{\gamma f}(y_n - z_n) \\
d_n = L x_n \\
y_{n+1} = \text{prox}_{\gamma g}(d_n + z_n) \\
z_{n+1} = z_n + d_n - y_{n+1}.
\end{cases}
\end{align*}
\]
for $n = 0, 1, \ldots$

This iteration process can be viewed as an application of the Douglas-Rachford algorithm (96) to the Fenchel dual of (122) [128], [120]. Variants of this algorithm are discussed in [12], [95], [119], and applications to image recovery in [2], [3], [126], [131], [137], [207].

D. Inconsistent feasibility problems

We consider a more structured variant of Problem 61 which can also be considered as an extension of Problem 62.

**Problem 81** Let $C$ be a nonempty closed convex subset of $\mathcal{H}$ and, for every $i \in \{1, \ldots, m\}$, let $L_i : \mathcal{H} \to G_i$ be a nonzero linear operator and let $D_i$ be a nonempty closed convex subset of $G_i$. The task is to
\[
\text{find } x \in C \text{ such that } (\forall i \in \{1, \ldots, m\}) \quad L_i x \in D_i.
\]

To address the possibility that this problem has no solution due to modeling errors [58], [76], [237], we fix weights $(\omega_i)_{1 \leq i \leq m}$ in $[0, 1]$ such that $\sum_{i=1}^{m} \omega_i = 1$ and consider the surrogate problem
\[
\min_{x \in C} \frac{1}{2} \sum_{i=1}^{m} \omega_i d_{D_i}^2(L_i x),
\]
where $C$ acts as a hard constraint. This is a valid relaxation of (124) in the sense that, if (124) does have solutions, then those are the only solutions to (125). Now set $f_0 = \gamma C$. In addition, for every $i \in \{1, \ldots, m\}$, set $f_i : x \mapsto (1/2)d_{D_i}^2(L_i x)$ and notice that $f_i$ is differentiable and that its gradient $\nabla f_i = L_i^* \circ (\text{Id} - \text{proj}_{D_i}) \circ L_i$ has Lipschitz constant $\delta_i = \|L_i\|^2$. Furthermore, (122) holds as long as $C$ is bounded or, for some $i \in \{1, \ldots, m\}$, $D_i$ is bounded and $L_i$ is invertible. We have thus cast (125) as an instance of Problem 75 [90]. In view of (114), a solution is found as the limit of the sequence $(x_n)_{n \in \mathbb{N}}$ produced by the block-update algorithm
\[
\begin{align*}
&\text{for } n = 0, 1, \ldots
&\quad \text{for every } i \in I_n
&\quad \quad t_{i,n} = x_n + \gamma L_i^* (\text{proj}_{D_i}(L_i x_n) - L_i x_n)
&\quad \text{for every } i \in \{1, \ldots, m\} \setminus I_n
&\quad \quad t_{i,n} = t_{i,n-1}
&\end{align*}
\]
\[
\begin{align*}
x_{n+1} = \text{proj}_{C}(\sum_{i=1}^{m} \omega_i t_{i,n}),
&\text{where } \gamma \text{ and } (I_n)_{n \in \mathbb{N}} \text{ are as in Proposition 76.}
\end{align*}
\]
E. Stochastic forward-backward method

Consider the minimization of $f + g$, where $f \in \Gamma_0(\mathcal{H})$ and $g: \mathcal{H} \to \mathbb{R}$ is a differentiable convex function. In certain applications, it may happen that only stochastic approximations to $f$ or $g$ are available. A generic stochastic form of the forward-backward algorithm for such instances is [98]

$$\left(\forall n \in \mathbb{N}\right)\ x_{n+1} = x_n + \lambda_n \left(\text{prox}_{\gamma_n f}(x_n - \gamma_n u_n) + a_n - x_n\right),$$

(127)

where $\gamma_n \in [0, +\infty]$, $\lambda_n \in [0, 1]$, $f_n \in \Gamma_0(\mathcal{H})$ is an approximation to $f$, $u_n$ is a random variable approximating $\nabla g(x_n)$, and $a_n$ is a random variable modeling a possible additive error. When $f = f_n = 0$, $\lambda_n = 1$, and $a_n = 0$, we recover the standard stochastic gradient method for minimizing $g$, which was pioneered in [123], [124].

Example 82 As in Problem 75, let $f \in \Gamma_0(\mathcal{H})$ and let $g = m^{-1} \sum_{i=1}^m g_i$, where each $g_i: \mathcal{H} \to \mathbb{R}$ is a differentiable convex function. The following specialization of (127) is obtained by setting, for every $n \in \mathbb{N}$, $f_n = f$ and $u_n = \nabla g_{(n)}(x_n)$, where $(n)$ is a $\{1, \ldots, m\}$-valued random variable. This leads to the incremental proximal stochastic gradient algorithm described by the update equation

$$x_{n+1} = x_n + \lambda_n \left(\text{prox}_{\gamma_n f}(x_n - \gamma_n \nabla g_{(n)}(x_n)) - x_n\right).$$

(128)

For related algorithms, see [28], [114], [115], [152], [204].

Various convergence results have been established for algorithm (127). If $\nabla g$ is Lipschitzian, (127) is closely related to the fixed point iteration in Theorem 45. The almost sure convergence of $(x_n)_{n \in \mathbb{N}}$ to a minimizer of $f + g$ can be guaranteed in several scenarios [6], [98], [198]. Fixed point strategies allow us to derive convergence results such as the following.

Theorem 83 ([98]) Let $f \in \Gamma_0(\mathcal{H})$, let $\delta \in [0, +\infty]$, and let $g: \mathcal{H} \to \mathbb{R}$ be a differentiable convex function such that $\nabla g$ is $\delta$-Lipschitzian and $S = \text{Argmin}(f + g) \neq \emptyset$. Let $\gamma \in [0, 2/\delta]$ and let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $[0, 1]$ such that $\sum_{n \in \mathbb{N}} \lambda_n = +\infty$. Let $x_0$, $(u_n)_{n \in \mathbb{N}}$, and $(a_n)_{n \in \mathbb{N}}$ be $\mathcal{H}$-valued random variables with finite second-order moments. Let $(x_n)_{n \in \mathbb{N}}$ be a sequence produced by (127) with $\gamma_n = \gamma$ and $f_n = f$. For every $n \in \mathbb{N}$, let $x_n$ be the $\sigma$-algebra generated by $(x_0, \ldots, x_n)$ and set $\mathcal{G}_n = \mathbb{E}(\|u_n - \mathbb{E}(u_n | x_n)\|^2 | x_n)$.

Assume that the following are satisfied a.s.:

i. $\sum_{n \in \mathbb{N}} \lambda_n \mathbb{E}\|u_n - \mathbb{E}(u_n | x_n)\|^2 | x_n\| < +\infty$.

ii. $\sum_{n \in \mathbb{N}} \lambda_n \mathbb{E}(u_n | x_n) - \nabla g(x_n)\| < +\infty$.

iii. $\sup_{n \in \mathbb{N}} \mathcal{G}_n < +\infty$ and $\sum_{n \in \mathbb{N}} \lambda_n \mathcal{G}_n < +\infty$.

Then $(x_n)_{n \in \mathbb{N}}$ converges a.s. to an $S$-valued random variable.

Extensions of these stochastic optimization approaches can be designed by introducing an inertial parameter [197] or by bringing into play primal-dual formulations [98].

F. Random block-coordinate optimization algorithms

We design block-coordinate versions of optimization algorithms presented in Section V-C, in which blocks of variables are updated randomly.

Problem 84 For every $i \in \{1, \ldots, m\}$ and $k \in \{1, \ldots, q\}$, let $f_i \in \Gamma_0(\mathcal{H}_i)$, let $g_k \in \Gamma_0(\mathcal{G}_k)$, and let $0 \neq L_{k,i}: \mathcal{H}_i \to \mathcal{G}_k$ be linear. Suppose that

$$\left(\exists z \in \mathcal{H}\right) \left(\exists w \in \mathcal{G}\right) (\forall i \in \{1, \ldots, m\})(\forall k \in \{1, \ldots, q\})$$

$$-q \sum_{j=1}^q L_{i,j}^* w_j \in \partial f_i(z_i) \quad \text{and} \quad \sum_{j=1}^m L_{k,j} z_j \in \partial g_k(w_k).$$

(129)

The task is to

$$\min_{x \in \mathcal{H}} \sum_{i=1}^m f_i(x_i) + \sum_{k=1}^q g_k \left(\sum_{i=1}^m L_{k,i} x_i\right).$$

(130)

Let $\gamma \in [0, +\infty]$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $[0, 2]$, and set

$$V = \{(x_1, \ldots, x_m, y_1, \ldots, y_q) \in \mathcal{H} \times \mathcal{G} : (\forall k \in \{1, \ldots, q\}) y_k = \sum_{i=1}^m L_{k,i} x_i\}.$$ 

(131)

Let us decompose $\text{proj}_V$ as $\text{proj}_V: x \mapsto (Q_j x)_{1 \leq j \leq m+q}$. A random block-coordinate form of the Douglas-Rachford algorithm for solving Problem 84 is [97]

for $n = 0, 1, \ldots$

for $i = 1, \ldots, m$

$$z_{i,n+1} = z_{i,n} + \varepsilon_{i,n} (Q_i(x_n, y_n) - z_{i,n})$$

$$x_{i,n+1} = x_{i,n} + \varepsilon_{i,n} \lambda_n \left(\text{prox}_{\gamma_n f_i}(2z_{i,n+1} - x_{i,n+1}) - x_{i,n+1}\right)$$

for $k = 1, \ldots, q$

$$w_{k,n+1} = w_{k,n} + \varepsilon_{m+k,n} (Q_{m+k}(x_n, y_n) - w_{k,n})$$

$$y_{k,n+1} = y_{k,n} + \varepsilon_{m+k,n} \lambda_n \left(\text{prox}_{\gamma_n g_k}(2w_{k,n+1} - y_{k,n+1}) - w_{k,n+1}\right),$$

(132)

where $x_n = (x_{i,n})_{1 \leq i \leq m}$ and $y_n = (y_{k,n})_{1 \leq k \leq q}$. Moreover, $(\varepsilon_{i,n})_{1 \leq i \leq m}$ and $(\varepsilon_{j,n})_{1 \leq j \leq q}$ are binary random variables signaling the activated components.

Proposition 85 ([97]) Let $S$ be the set of solutions to Problem 84 and set $D = \{0, \ldots, m+q\} \setminus \{0\}$. Let $\gamma \in [0, +\infty]$, let $\varepsilon \in [0, 1]$, let $(\lambda_n)_{n \in \mathbb{N}}$ be in $[\varepsilon, \varepsilon - \varepsilon]$, let $x_0$ and $z_0$ be $\mathcal{H}$-valued random variables, let $y_0$ and $w_0$ be $\mathcal{G}$-valued random variables, and let $(\varepsilon_n)_{n \in \mathbb{N}}$ be identically distributed $\mathcal{D}$-valued random variables. In addition, suppose that the following hold:

i. For every $n \in \mathbb{N}$, $\varepsilon_n$ and $(x_0, \ldots, x_n, y_0, \ldots, y_n)$ are mutually independent.

ii. $(\forall j \in \{1, \ldots, m+q\}) \text{Prob}(\varepsilon_{j,0} = 0) > 0$.

Then the sequence $(z_n)_{n \in \mathbb{N}}$ generated by (132) converges a.s. to an $S$-valued random variable.

Applications based on Proposition 85 appear in the areas of machine learning [91] and binary logistic regression [39].
If the functions \((g_k)_{1 \leq k \leq q}\) are differentiable in Problem 84, a block-coordinate version of the forward-backward algorithm can also be employed, namely,

\[
\begin{align*}
  & \text{for } n = 0, 1, \ldots, \\
  & \text{for } i = 1, \ldots, m \\
  & r_{i,n} = \varepsilon_{i,n} (x_{i,n} - \\
  & \quad \quad \gamma_{i,n} \sum_{k=1}^{q} L_{k,i} \left( \nabla g_k \sum_{j=1}^{m} L_{k,j} x_{j,n} \right) ) \\
  & x_{i,n+1} = x_{i,n} + \varepsilon_{i,n} \lambda_n (\text{prox}_{\gamma_{i,n} f_i} r_{i,n} - x_{i,n}),
\end{align*}
\]

(133)

where \(\gamma_{i,n} \in [0, +\infty[\) and \(\lambda_n \in [0, 1]\). The convergence of (133) has been investigated in various settings in terms of the expected value of the cost function [179], [193], [194], [201], the mean square convergence of the iterates [99], [193], [194], or the almost sure convergence of the iterates [97], [201]. It is shown in [201] that algorithms such as the so-called random Kaczmarz method to solve standard linear systems are special cases of (133).

A noteworthy feature of the block-coordinate forward-backward algorithm (133) is that, at iteration \(n\), it allows for the use of distinct parameters \(\gamma_{i,n}\) to update each component. This was observed to be beneficial to the convergence profile in several applications [71], [193]. See also [201] for further developments along these lines.

**G. Block-iterative multivariate minimization algorithms**

We investigate a specialization of a primal-dual version of the multivariate inclusion Problem 59 in the context of Problem 84.

**Problem 86** Consider the setting of Problem 84. The task is to solve the primal minimization problem

\[
\begin{align*}
  & \text{minimize } \sum_{i=1}^{m} f_i(x_i) + \sum_{k=1}^{q} g_k \left( \sum_{i=1}^{m} L_{k,i} x_i \right), \quad (134)
\end{align*}
\]

along with its dual problem

\[
\begin{align*}
  & \text{minimize } \sum_{i=1}^{m} f_i^*( - \sum_{k=1}^{q} L_{k,i}^* v_{k,i}^* + \sum_{k=1}^{q} g_k^* (v_{k,i}^*)), \quad (135)
\end{align*}
\]

We solve Problem 86 with algorithm (82) by replacing \(J_{\gamma_{i,n} A_i}\) by \(\text{prox}_{\gamma_{i,n} f_i}\) and \(J_{\mu_{k,n} B_k}\) by \(\text{prox}_{\mu_{k,n} g_k}\). This block-iterative method then produces a sequence \((x_n)_{n \in \mathbb{N}}\) which converges to a solution to (134) and a sequence \((v_{n,i}^*)_{n \in \mathbb{N}}\) which converges to a solution to (135) [87].

Examples of problems that conform to the format of Problems 84 or 86 are encountered in image processing [26], [40], [43] as well as in machine learning [4], [9], [91], [150], [151], [170], [225], [240].

**H. Splitting based on Bregman distances**

The notion of a Bregman distance goes back to [37] and it has been used since the 1980s in signal recovery [51], [59]. Let \(\varphi \in \Gamma_0(H)\) be strictly convex, and differentiable on \(\text{int dom } \varphi \neq \emptyset\) (more precisely, we require a Legendre function, see [16], [17] for the technical details). The associated Bregman distance between two points \(x, y\) in \(H\) is

\[
D_{\varphi}(x, y) = \begin{cases} \varphi(x) - \varphi(y) - \langle x - y, \nabla \varphi(y) \rangle, & \text{if } y \in \text{int dom } \varphi; \\ +\infty, & \text{otherwise}. \end{cases}
\]

This construction captures many interesting discrepancy measures in data analysis such as the Kullback-Leibler divergence. Another noteworthy instance is when \(\varphi = \| \cdot \|^2/2\), which yields \(D_{\varphi}(x, y) = \|x - y\|^2/2\) and suggests extending standard tools such as projection and proximity operators (see Theorems 1 and 2) by replacing the quadratic kernel by a Bregman distance. For instance, under mild conditions on \(f \in L_0(H)\) [17], the Bregman proximal point of \(y \in \text{int dom } \varphi\) relative to \(f\) is the unique point \(\text{prox}_{f} \varphi y\) which solves

\[
\begin{align*}
  \text{minimize } f(p) + D_{\varphi}(p, y).
\end{align*}
\]

The Bregman projection \(\text{proj}_{\varphi}^C y\) of \(y\) onto a nonempty closed convex set \(C\) in \(H\) is obtained by setting \(f = \iota_C\) above. Various algorithms such as the POCS algorithm (85) or the proximal point algorithm (94) have been extended in the context of Bregman distances [16], [17]. For instance [16] establishes the convergence to a solution to Problem 61 of a notable extension of POCS in which the sets are Bregman-projected onto in arbitrary order, namely

\[
\begin{align*}
  (\forall n \in \mathbb{N} ) \quad x_{n+1} = \text{proj}^{\varphi}_{C_{i(n)}} \, x_n,
\end{align*}
\]

(138)

where \(i : \mathbb{N} \to \{1, \ldots, m\}\) is such that, for every \(p \in \mathbb{N}\) and every \(j \in \{1, \ldots, m\}\), there exists \(n \geq p\) such that \(i(n) = j\).

A motivation for such extensions is that, for certain functions, proximal points are easier to compute in the Bregman sense than in the standard quadratic sense [14], [93], [180]. Some work has also focused on monotone operator splitting using Bregman distances as an extension of standard methods [93]. The Bregman version of the basic forward-backward minimization method of Proposition 70, namely,

\[
\begin{align*}
  & u_n = \nabla \varphi(x_n) - \gamma_n \nabla g(x_n) \\
  & x_{n+1} = \left( \nabla \varphi + \gamma_n \partial f \right)^{-1} u_n
\end{align*}
\]

(139)

has also been investigated in [14], [46], [180] (note that the standard quadratic kernel corresponds to \(\nabla \varphi = \text{Id}\)). In these papers, it was shown to converge in instances when (105) cannot be used because \(\nabla g\) is not Lipschitzian.

**VI. FIXED POINT MODELING OF NASH EQUILIBRIA**

In addition to the notation of Section **II-A**, given \(i \in \{1, \ldots, m\}\), \(x_i \in \mathcal{H}_i\), and \(y \in \mathcal{H}\), we set

\[
\begin{align*}
  \mathcal{H}_{i-1} \times \cdots \times \mathcal{H}_{i-1} \times \mathcal{H}_{i+1} \times \cdots \times \mathcal{H}_m
\end{align*}
\]

(140)

In various problems arising in signal recovery [7], [8], [26], [40], [43], [109], [110], [116], telecommunications [161], [205], machine learning [36], [111], network science [233],
[235], and control [24], [31], [243], the solution is not a single vector but a collections of vectors \( x = (x_1, \ldots, x_m) \in \mathcal{H} \) representing the actions of \( m \) competing players. Oftentimes, such solutions cannot be modeled via a standard minimization problem of the form

\[
\text{minimize } h(x)
\]  

for some function \( h: \mathcal{H} \to [-\infty, +\infty] \), but rather as a Nash equilibrium. In this game-theoretic setting [160], player \( i \) aims at minimizing his individual loss (or negative payoff) function \( h_i: \mathcal{H} \to [-\infty, +\infty] \), that incorporates the actions of the other players. An action profile \( \varpi \in \mathcal{H} \) is called a Nash equilibrium if and only if

\[
(h_i(\varpi; \varpi_{\neq i}) = \min_{x_i \in H_i} h_i(x_i; \varpi_{\neq i}) \quad \forall i \in \{1, \ldots, m\})
\]

In other words, if

\[
\text{best}_i: \mathcal{H}_{\neq i} \to 2^{H_i}: x_{\neq i} \mapsto \{x_i \in H_i \mid (\forall y_i \in H_i) h_i(y_i; x_{\neq i}) \geq h_i(x_i; x_{\neq i})\}
\]

denotes the best response operator of player \( i \), \( \varpi \in \mathcal{H} \) is a Nash equilibrium if and only if

\[
(\forall i \in \{1, \ldots, m\}) \quad \varpi_i \in \text{best}_i(\varpi_{\neq i}).
\]

This property can also be expressed in terms of the set-valued operator

\[
B: \mathcal{H} \to 2^\mathcal{H}: x \mapsto \text{best}_1(x_{\neq 1}) \times \cdots \times \text{best}_m(x_{\neq m}).
\]

Thus, a point \( \varpi \in \mathcal{H} \) is a Nash equilibrium if and only if it is a fixed point of \( B \) in the sense that \( \varpi \in B\varpi \).

A. Cycles in the POCS algorithm

Let us go back to feasibility and Problem 61. The POCS algorithm (85) converges to a solution to the feasibility problem (83) when one exists. Now suppose that Problem 61 is inconsistent, with \( C_1 \) bounded. Then, as seen in Example 74, in the case of \( m = 2 \) sets, the sequence \((x_{2n})_{n \in \mathbb{N}}\) produced by the alternating projection algorithm (110), written as

\[
\begin{align*}
  &x_{2n+1} = \text{proj}_{C_2}x_{2n} \\
  &x_{2n+2} = \text{proj}_{C_1}x_{2n+1},
\end{align*}
\]

converges to a point \( \varpi_1 \in \text{Fix}(\text{proj}_{C_1} \circ \text{proj}_{C_2}) \), i.e., to a minimizer of \( d_{C_2} \) over \( C_1 \). More precisely [65], if we set \( \varpi_2 = \text{proj}_{C_2}\varpi_1 \), then \( \varpi_1 = \text{proj}_{C_1}\varpi_2 \) and \((\varpi_1, \varpi_2)\) solves

\[
\text{minimize } x_1 \in C_1, x_2 \in C_2 \|x_1 - x_2\|.
\]

An extension of the alternating projection method (146) to \( m \) sets is the POCS algorithm (85), which we write as

\[
\begin{align*}
  &x_{mn+1} = \text{proj}_{C_m}x_{mn} \\
  &x_{mn+2} = \text{proj}_{C_{m-1}}x_{mn+1} \\
  &\vdots \\
  &x_{mn+m} = \text{proj}_{C_1}x_{mn+m-1}.
\end{align*}
\]

As first shown in [140] (this is also a consequence of Theorem 41), for every \( i \in \{1, \ldots, m\} \), \((x_{mn+i})_{n \in \mathbb{N}}\) converges to a point \( \varpi_{m+1-i} \in C_{m+1-i} \); in addition \((\varpi_i)_{1 \leq i \leq m}\) forms a cycle in the sense that (see Fig. 6)

\[
\begin{align*}
  \varpi_1 = \text{proj}_{C_1}\varpi_2, \ldots, \varpi_m = \text{proj}_{C_m}\varpi_1.
\end{align*}
\]

As shown in [11], in stark contrast with the case of \( m = 2 \), sets and (147), there exists no function \( \Phi: \mathcal{H}^m \to \mathbb{R} \) such that cycles solve the minimization problem

\[
\text{minimize } x_1 \in C_1, \ldots, x_m \in C_m \Phi(x_1, \ldots, x_m),
\]

which deprives cycles of a minimization interpretation. Nonetheless, cycles are equilibria in a more general sense, which can be described from three different perspectives.

- Fixed point theory: Define two operators \( P \) and \( L \) from \( \mathcal{H}^m \) to \( \mathcal{H}^m \) by

\[
\begin{align*}
  P: x \mapsto (\text{proj}_{C_1}x_1, \ldots, \text{proj}_{C_m}x_m) \\
  L: x \mapsto (x_2, \ldots, x_m, x_1)
\end{align*}
\]

Then, in view of (149), the set of cycles is precisely the set of fixed points of \( P \circ L \), which is also the set of fixed points of \( T = P \circ F \), where \( F = (\text{Id} + L)/2 \) (see [19, Corollary 26.3]). Since Example 11 implies that \( P \) is firmly nonexpansive and since \( L \) is nonexpansive, \( F \) is firmly nonexpansive as well. It thus follows from Example 19, that the cycles are the fixed points of the 2/3-averaged operator \( T \).

- Game theory: Consider a game in \( \mathcal{H}^m \) in which the goal of player \( i \) is to minimize the loss

\[
\begin{align*}
  h_i: \{x_i; x_{\neq i}\} \mapsto t_{C_i}(x_i) + \frac{1}{2}\|x_i - x_{i+1}\|^2,
\end{align*}
\]

i.e., to be in \( C_i \) and as close as possible to the action of player \( i + 1 \) (with the convention \( x_{m+1} = x_1 \)). Then a cycle \((\varpi_1, \ldots, \varpi_m)\) is a solution to (142) and therefore a Nash equilibrium. Let us note that the best response operator of player \( i \) is \( \text{best}_i: x_{\neq i} \mapsto \text{proj}_{C_i}x_{i+1} \).
• Monotone inclusion: Applying Fermat’s rule to each line of (142) in the setting of (152), and using (14), we obtain

\[
\begin{align*}
0 & \in N_{C_1} \varpi_1 + \varpi_1 - \varpi_2 \\
& \vdots \\
0 & \in N_{C_{m-1}} \varpi_{m-1} + \varpi_{m-1} - \varpi_m \\
0 & \in N_{C_m} \varpi_m + \varpi_m - \varpi_1.
\end{align*}
\] (153)

In terms of the maximally monotone operator \( A = N_{C_1 \times \cdots \times C_m} \) and the cocoercive operator

\[
B : x \mapsto (x_1 - x_2, \ldots, x_{m-1} - x_m, x_m - x_1),
\] (154)

(153) can be rewritten as an instance of Problem 47 in \( \mathcal{H}^m \), namely, \( 0 \in A \varpi + B \varpi \).

B. Proximal cycles

We have seen in Section VI-A a first example of a Nash equilibrium. This setting can be extended by replacing the indicator function \( \iota_{C_i} \) in (152) by a general function \( \varphi_i \in \Gamma_0(\mathcal{H}) \) modeling the self-loss of player \( i \), i.e.,

\[
h_i : (x_i, x_{-i}) \mapsto \varphi_i(x_i) + \frac{1}{2} \| x_i - x_{i+1} \|^2.
\] (155)

The solutions to the resulting problem (142) are proximal cycles, i.e., \( m \)-tuples \( (\varpi_i)_{1 \leq i \leq m} \in \mathcal{H}^m \) such that

\[
\varpi_1 = \text{prox}_{\varphi_1} \varpi_2, \ldots, \varpi_{m-1} = \text{prox}_{\varphi_{m-1}} \varpi_m, \quad \text{and} \quad \varpi_m = \text{prox}_{\varphi_m} \varpi_1.
\] (156)

Furthermore, the equivalent monotone inclusion and fixed point representations of the cycles in Section VI-A remain true with

\[
P : \mathcal{H} \to \mathcal{H} : x \mapsto (\text{prox}_{\varphi_1} x_1, \ldots, \text{prox}_{\varphi_m} x_m)
\] (157)

and \( A = \partial f \), where \( f : x \mapsto \sum_{i=1}^m \varphi_i(x_i) \). Here, the best response operator of player \( i \) is best\(_i \) : \( x_{-i} \mapsto \text{prox}_{\varphi_i} x_{i+1} \). Examples of such cycles appear in [40], [103].

C. Construction of Nash equilibria

A more structured version of the Nash equilibrium formulation (142), which captures (155) and therefore (152), is provided next.

Problem 87 For every \( i \in \{1, \ldots, m\} \), let \( \psi_i \in \Gamma_0(\mathcal{H}_i) \), let \( f_i : \mathcal{H} \to [-\infty, +\infty] \), let \( g_i : \mathcal{H} \to [-\infty, +\infty] \) be such that, for every \( x \in \mathcal{H} \), \( f_i(\cdot; x_{-i}) \in \Gamma_0(\mathcal{H}_i) \) and \( g_i(\cdot; x_{-i}) \in \Gamma_0(\mathcal{H}_i) \). The task is to

find \( \varpi \in \mathcal{H} \) such that \( (84, 2) \)

\[
\varpi_i \in \text{Argmin}_{x_i \in \mathcal{H}_i} \psi_i(x_i) + f_i(x_i; \varpi_{-i}) + g_i(x_i; \varpi_{-i}).
\] (158)

Under suitable assumptions on \( (f_i)_{1 \leq i \leq m} \) and \( (g_i)_{1 \leq i \leq m} \), monotone operator splitting strategies can be contemplated to solve Problem 87. This approach was initiated in [74] in a special case of the following setting, which reduces to that investigated in [42] when \( (84, 2) \)

Assumption 88 In Problem 87, the functions \( (f_i)_{1 \leq i \leq m} \) coincide with a function \( f \in \Gamma_0(\mathcal{H}) \). For every \( i \in \{1, \ldots, m\} \) and every \( x \in \mathcal{H} \), \( g_i(\cdot; x_{-i}) \) is differentiable on \( \mathcal{H}_i \) and \( \nabla g_i(x) \) denotes its derivative relative to \( x_i \). Moreover,

\[
(\forall x \in \mathcal{H})(\forall y \in \mathcal{H}) \sum_{i=1}^m (\nabla_i g_i(x) - \nabla_i g_i(y) | x_i - y_i) \geq 0,
\] (159)

and

\[
(\exists z \in \mathcal{H}) - (\nabla_1 g_1(z), \ldots, \nabla_m g_m(z)) \in \partial f(z) + \bigoplus_{i=1}^m \partial \psi_i(z_i).
\] (160)

In the context of Assumption 88, let us introduce the maximally monotone operators on \( \mathcal{H} \)

\[
\begin{align*}
A = \partial f \\
B : x \mapsto \bigoplus_{i=1}^m \partial \psi_i(x_i) \\
C : x \mapsto (\nabla_1 g_1(x), \ldots, \nabla_m g_m(x)).
\end{align*}
\] (161)

Then the solutions to the inclusion problem (see Problem 51) \( 0 \in Ax + Bx + Cx \) solve Problem 87 [42]. In turn, applying the splitting scheme of Proposition 52 leads to the following implementation.

Proposition 89 Consider the setting of Assumption 88 with the additional requirement that, for some \( \delta \in [0, +\infty] \),

\[
(\forall x \in \mathcal{H})(\forall y \in \mathcal{H}) \sum_{i=1}^m \| \nabla_i g_i(x) - \nabla_i g_i(y) \|^2 \leq \delta^2 \sum_{i=1}^m \| x_i - y_i \|^2.
\] (162)

Let \( \varepsilon \in [0, 1/(2+\delta)] \), let \( (\gamma_n)_{n \in \mathbb{N}} \) be in \( [\varepsilon, (1-\varepsilon)/(1+\delta)] \), let \( \varphi_0 \in \mathcal{H} \), and let \( v_0 \in \mathcal{H} \). Iterate

for \( n = 0, 1, \ldots \)

for \( i = 1, \ldots, m \)

\[
\begin{align*}
y_{i,n} & = x_{i,n} - \gamma_n (\nabla_i g_i(x_{i,n}) + v_{i,n}) \\
P_{n} & = \text{prox}_{\gamma_n f} y_n \\
q_{i,n} & = v_{i,n} + \gamma_n (x_{i,n} - \text{prox}_{\gamma_n f} (v_{i,n}/\gamma_n + x_{i,n})) \\
x_{i,n+1} & = x_{i,n} - y_{i,n} + p_{i,n} + \psi_i(x_{i,n+1})
\end{align*}
\] (163)

Then there exists a solution \( \varpi \) to Problem 87 such that, for every \( i \in \{1, \ldots, m\} \), \( x_{i,n} \to \varpi_i \).

Example 90 Let \( \varphi_1 : \mathcal{H}_1 \to \mathbb{R} \) be convex and differentiable with a \( \delta_1 \)-Lipschitzian gradient, let \( \varphi_2 : \mathcal{H}_2 \to \mathbb{R} \) be convex and differentiable with a \( \delta_2 \)-Lipschitzian gradient, let \( L : \mathcal{H}_1 \to \mathcal{H}_2 \) be linear, and let \( C_1 \subset \mathcal{H}_1, C_2 \subset \mathcal{H}_2 \), and \( D \subset \mathcal{H}_1 \times \mathcal{H}_2 \) be nonempty closed convex sets. Suppose that there exists \( z \in \mathcal{H}_1 \times \mathcal{H}_2 \) such that \( -\nabla \varphi_1(z_1) + \cdots + \nabla \varphi_m(z_m) \in D \). Then there exists a solution \( \varpi \) to Problem 87 such that, for every \( i \in \{1, \ldots, m\} \), \( x_{i,n} \to \varpi_i \).
\[ L^* z_2, \nabla \varphi_2 (z_2) - L z_1 \in N_D (z_1, z_2) + N_{C_1} z_1 \times N_{C_2} z_2. \]

Then the 2-player game

\[
\begin{align*}
\forall x_1 \in C_1 & \quad \psi_1 (x_1) + \langle L x_1 \mid \tau_2 \rangle \\
\forall x_2 \in C_2 & \quad \psi_2 (x_2) - \langle L^* \tau_1 \mid x_2 \rangle
\end{align*}
\]

is an instance of Problem 87 with \( f_1 = f_2 = \iota_D \), \( \psi_1 = \iota_{C_1} \), and \( \psi_2 = \iota_{C_2} \), and

\[
\begin{align*}
g_1 : (x_1, x_2) & \mapsto \varphi_1 (x_1) + \langle L x_1 \mid x_2 \rangle \\
g_2 : (x_1, x_2) & \mapsto \varphi_2 (x_2) - \langle L^* \tau_1 \mid x_2 \rangle.
\end{align*}
\]

In addition, Assumption 88 is satisfied, as well as (162) with \( \delta = \max \{ \delta_1, \delta_2 \} + ||L|| \). Moreover, in view of (11), algorithm (163) becomes

\[
\begin{align*}
\text{for } n = 0, 1, \ldots \quad & y_{1,n} = x_{1,n} - \gamma_n \left( \nabla \varphi_1 (x_{1,n}) + L^* x_{2,n} + v_{1,n} \right) \\
y_{2,n} = x_{2,n} - \gamma_n \left( \nabla \varphi_2 (x_{2,n}) - L x_{1,n} + v_{2,n} \right) \\
P_n & = \text{proj} \frac{1}{P_n} \left( v_{1,n} + \gamma_n \left( \nabla \varphi_1 (x_{1,n}) - L^* x_{2,n} + v_{1,n} \right) \right) \\
q_{1,n} & = y_{1,n} + \gamma_n \left( \nabla \varphi_1 (x_{1,n}) - L x_{2,n} + v_{1,n} \right) \\
q_{2,n} & = y_{2,n} + \gamma_n \left( \nabla \varphi_2 (x_{2,n}) - L x_{1,n} + v_{2,n} \right) \\
x_{1,n+1} & = x_{1,n} - \gamma_n \left( \nabla \varphi_2 (x_{2,n}) + L^* p_{2,n} + v_{1,n} \right) \\
x_{2,n+1} & = x_{2,n} - \gamma_n \left( \nabla \varphi_2 (x_{2,n}) - L p_{1,n} + v_{2,n} \right) \\
\text{for } n = 0, 1, \ldots \quad & z_{i,n} = \text{proj} \frac{1}{P_i} \left( v_{i,n} + \gamma_n \left( \nabla \varphi_i (x_{i,n}) - L x_{i,n} + v_{i,n} \right) \right) \\
\text{for } i = 1, \ldots, m \quad & f_i : x \mapsto \sum_{i=1}^m \frac{1}{\lambda_i} \text{proj}_{C_i} (x_{i,n})
\end{align*}
\]

Condition (162) means that the operator \( C \) of (161) is \( \delta \)-Lipschitzian. The stronger assumption that it is cocoercive, allows us to bring into play the three-operator splitting algorithm of Proposition 53 to solve Problem 87.

**Proposition 91** Consider the setting of Assumption 88 with the additional requirement that, for some \( \beta \in \left[ 0, +\infty \right[ \)

\[
(\forall x \in \mathcal{H})(\forall y \in \mathcal{H}) \sum_{i=1}^m \langle x_i - y_i \mid \nabla_i g_i (x) - \nabla_i g_i (y) \rangle \geq \beta \sum_{i=1}^m \| \nabla_i g_i (x) - \nabla_i g_i (y) \|^2.
\]

Let \( \gamma \in [0, 2\beta] \) and set \( \alpha = 2\beta/(4\beta - \gamma) \). Furthermore, let \( (\lambda_n)_{n \in \mathbb{N}} \) be an \( \alpha \)-relaxation sequence and let \( y_0 \in \mathcal{H} \). Iterate

\[
\begin{align*}
\text{for } n = 0, 1, \ldots \\
\text{for } i = 1, \ldots, m & \quad x_{i,n} = \text{proj}_{\gamma \psi_i y_{i,n}} y_{i,n} \\
r_{i,n} & = y_{i,n} + \gamma \nabla \varphi_i (x_{i,n}) \\
z_{i,n} & = \text{proj}_{\varphi_i \psi_i} (2 x_{i,n} - r_{i,n}) \\
y_{i,n+1} = y_{i,n} + \lambda_n (z_{i,n} - x_{i,n}).
\end{align*}
\]

Then there exists a solution \( \bar{x} \) to Problem 87 such that, for every \( i = 1, \ldots, m \), \( x_{i,n} \rightarrow \bar{x}_i \).

**Example 92** For every \( i = 1, \ldots, m \), let \( C_i \subset \mathcal{H}_i \) be a nonempty closed convex set, let \( L_i : \mathcal{H}_i \rightarrow \mathcal{G} \) be linear, and let \( o_i \in \mathcal{G} \). The task is to solve the Nash equilibrium (with the convention \( L_{m+1} = 1 \))

\[
\begin{align*}
\text{find } \bar{x} & \in \mathcal{H} \text{ such that } (\forall i \in \{ 1, \ldots, m \}) \\
\bar{x}_i & \in \text{Argmin} \| L_i x_i + L_{i+1} x_{i+1} - o_i \|^2.
\end{align*}
\]

Fig. 7: Feedforward neural network: the \( i \)-th layer involves a linear weight operator \( W_i \), a bias vector \( b_i \), and an activation operator \( R_i \), which is assumed to be an averaged nonexpansive operator.

\[
\begin{align*}
\text{for } i = 1, \ldots, m & \quad x_{i,n} = \text{proj}_{\gamma \psi_i y_{i,n}} y_{i,n} \\
r_{i,n} & = y_{i,n} + \gamma \nabla \varphi_i (x_{i,n}) \\
z_{i,n} & = \text{proj}_{\varphi_i \psi_i} (2 x_{i,n} - r_{i,n}) \\
y_{i,n+1} = y_{i,n} + \lambda_n (z_{i,n} - x_{i,n}).
\end{align*}
\]

**Remark 93**

i) As seen in Example 90, the functions of (165) satisfy the Lipschitz condition (162). However the cocoercivity condition (167) does not hold. For instance, if \( \varphi_1 = 0 \) and \( \varphi_2 = 0 \) then, for every \( x \) and \( y \) in \( \mathcal{H}_1 \times \mathcal{H}_2 \),

\[
\begin{align*}
\langle \nabla_1 g_1 (x) - \nabla_1 g_1 (y) \mid x_1 - y_1 \rangle \\
+ \langle \nabla_2 g_2 (x) - \nabla_2 g_2 (y) \mid x_2 - y_2 \rangle & = 0.
\end{align*}
\]

ii) Distributed splitting algorithms for finding Nash equilibria are discussed in [23], [24], [233], [234].

iii) An asynchronous block-iterative decomposition algorithm to solve Nash equilibrium problems involving a mix of nonsmooth and smooth functions acting on linear mixtures of actions is proposed in [47].

**VII. FIXED POINT MODELING OF OTHER NON-MINIMIZATION PROBLEMS**

**A. Neural network structures**

A feedforward neural network (see Fig. 7) consists of the composition of nonlinear activation operators and affine
operators. More precisely, such an $m$-layer network can be modeled as
\[ T = T_m \circ \cdots \circ T_1, \]
where $T_i = R_i \circ (W_i \cdot + b_i)$, with $W_i \in \mathbb{R}^{N_i \times N_{i-1}}$, $b_i \in \mathbb{R}^{N_i}$, and $R_i : \mathbb{R}^{N_i} \to \mathbb{R}^{N_i}$ (see Fig. 7). If the $i$-th layer is convolutional, then the corresponding weight matrix $W_i$ has a Toeplitz (or block-Toeplitz) structure. Many common activation operators are separable, i.e.,
\[ R_i : (\xi_k)_{1 \leq k \leq N_i} \mapsto (\theta_{i,k}(\xi_k))_{1 \leq k \leq N_i}, \]
where $\theta_{i,k} : \mathbb{R} \to \mathbb{R}$. For example, the ReLU activation function is given by
\[ \theta_{i,k} : \xi \mapsto \begin{cases} \xi, & \text{if } \xi > 0; \\ 0, & \text{if } \xi \leq 0, \end{cases} \]
and the unimodal sigmoid activation function is
\[ \theta_{i,k} : \xi \mapsto \frac{1}{1 + e^{-\xi}} - \frac{1}{2}. \]
An example of a nonseparable operator is the softmax activator
\[ R_i : (\xi_k)_{1 \leq k \leq N_i} \mapsto \left( e^{\xi_k} / \sum_{j=1}^{N_i} e^{\xi_j} \right)_{1 \leq k \leq N_i}. \]
It was observed in [101] that almost all standard activators are actually averaged operators in the sense of (21). In particular, as discussed in [100], many activators are proximity operators in the sense of Theorem 2. In this case, in (173), there exist functions $(\phi_k)_{1 \leq k \leq N_i}$ in $\Gamma_0(\mathbb{R})$ such that
\[ R_i : (\xi_k)_{1 \leq k \leq N_i} \mapsto (\text{prox}_{\phi_k})_{1 \leq k \leq N_i}. \]
For ReLU, $\phi_k$ reduces to $\chi_{[0,+\infty)}$ whereas, for the unimodal sigmoid, it is the function
\[ \xi \mapsto \begin{cases} ((\xi + 1/2) \ln (\xi + 1/2) + (1/2 - \xi) \ln (1/2 - \xi)) - (|\xi|^2 + 1/4)/2, & \text{if } |\xi| < 1/2; \\ -1/4, & \text{if } \xi = 1/2; \\ +\infty, & \text{if } |\xi| > 1/2. \end{cases} \]
For softmax, we have $R_i = \text{prox}_{\varphi_i}$, where
\[ \varphi_i : (\xi_k)_{1 \leq k \leq N_i} \mapsto \begin{cases} \sum_{i=1}^{N_i} (\xi_k \ln \xi_k - |\xi_k|^2)/2, & \text{if } \min_{1 \leq k \leq N_i} \xi_k \geq 0 \text{ and } \sum_{k=1}^{N_i} \xi_k = 1; \\ +\infty, & \text{otherwise}. \end{cases} \]
The weight matrices $(W_j)_{1 \leq j \leq m}$ play a crucial role in the overall nonexpansiveness of the network. Indeed, under suitable conditions on these matrices, the network $T$ is averaged. For example, let $W = W_m \cdots W_1$ and let
\[ \theta_m = \|W\| + \sum_{\ell=1}^{m-1} \sum_{0 \leq j_1 < \cdots < j_{\ell} \leq m-1} \|W_m \cdots W_{j_{\ell}+1}\| \times \|W_{j_{\ell}} \cdots W_{j_{\ell-1}+1}\| \cdots \|W_{j_1} \cdots W_0\|. \]
Then, if there exists $\alpha \in [1/2, 1]$ such that
\[ \|W - 2^m (1-\alpha) \text{Id}\| - \|W\| + 2\theta_m \leq 2^m \alpha, \]
$T$ is $\alpha$-averaged. Other sufficient conditions have been established in [100]. These results pave the way to a theoretical analysis of neural networks from the standpoint of fixed point methods. In particular, assume that $N_m = N_0$ and consider a recurrent network of the form
\[ (\forall n \in \mathbb{N}) \quad x_{n+1} = (1 - \lambda_n)x_n + \lambda_n T x_n, \]
where $\lambda_n \in [0, +\infty]$ models a skip connection. Then, according to Theorem 37, the convergence of $(x_n)_{n \in \mathbb{N}}$ to a fixed point of $T$ is guaranteed under condition (181) provided that $(\lambda_n)_{n \in \mathbb{N}}$ is an $\alpha$-relaxation sequence. As shown in [100], when for every $i \in \{1, \ldots, m\}$, $R_i$ is the proximity operator of some function $\varphi_i \in \Gamma_0(\mathbb{R}^{N_i})$, the recurrent network delivers asymptotically a solution to the system of inclusions
\[ \begin{aligned} b_1 & \in \varphi_1 - W_1 \varphi_1 + \partial \varphi_1(\varphi_1) \\ b_2 & \in \varphi_2 - W_2 \varphi_2 + \partial \varphi_2(\varphi_2) \\ & \vdots \\ b_m & \in \varphi_m - W_m \varphi_m - \partial \varphi_m(\varphi_m), \end{aligned} \]
where $\varphi_m \in \text{Fix} \, T$ and, for every $i \in \{2, \ldots, m\}$, $\varphi_i = T \varphi_{i-1}$. Alternatively, (183) is a Nash equilibrium of the form (142) where (we set $\varphi_0 = \varphi_m$)
\[ h : (x_i; \varphi_{i-1}) \mapsto \varphi_i(x_i) + \frac{1}{2} \|x_i - b_i - W_i \varphi_{i-1}\|^2. \]
Fixed point theory also allows us to provide conditions for $T$ to be Lipschitzian and to calculate an associated Lipschitz constant. Such results are useful to evaluate the robustness of the network to adversarial perturbations of its input [213]. As shown in [101], if $\theta_m$ is given by (180), $\theta_m/2^{m-1}$ is a Lipschitz constant of $T$ and
\[ \|W\| \leq \frac{\theta_m}{2^{m-1}} \leq \|W_1\| \cdots \|W_m\|. \]
This bound is thus more accurate than the product of the individual bounds corresponding to each layer used in [213]. Tighter estimations can also be derived, especially when the activation operators are separable [101], [162], [202]. Note that the lower bound in (185) would correspond to a linear network where all the nonlinear activation operators would be removed. Interestingly, when all the weight matrices have nonnegative components, $\|W\|$ is a Lipschitz constant of the network [101].

Special cases of the neural network model of [100] are investigated in [141], [214]. Another special case of interest is when the operator $T$ in (172) corresponds to the unrolling (or unrolling) of a fixed point algorithm, that is each $T_i$ with $i \in \{1, \ldots, m\}$ corresponds to one iteration of such an algorithm [13], [138], [232], [242]. The algorithm parameters, as well as possible hyperparameters of the problem, can then be optimized from a training set by using differentiable programming. Let us note that the results of [100], [101] can be used to characterize the nonexpansiveness properties of the resulting neural network [27].
B. Plug-and-play methods

The principle of the so-called plug-and-play (PnP) methods [48], [182], [195], [199], [212], [224] is to replace a proximity operator appearing in some proximal minimization algorithm by another operator $Q$. The rationale is that, since a proximity operator can be interpreted as a denoiser [103], one can consider replacing this proximity operator by a more sophisticated denoiser $Q$, or even learning it in a supervised manner from a database of examples. Example 72 described implicitly a PnP algorithm that can be interpreted as a minimization problem. Here are some techniques that go beyond the optimization setting.

Algorithm 94 (PnP forward-backward) Let $f : \mathcal{H} \to \mathbb{R}$ be a differentiable convex function, $Q : \mathcal{H} \to \mathcal{H}$, let $\gamma \in [0, +\infty[$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $]0, +\infty[$, and let $x_0 \in \mathcal{H}$. Iterate
\[
\begin{align*}
\text{for } n = 0, 1, \ldots \\
y_n &= x_n - \gamma \nabla f(x_n) \\
x_{n+1} &= x_n + \lambda_n (Q y_n - x_n).
\end{align*}
\]

The convergence of $(x_n)_{n \in \mathbb{N}}$ in (186) is related to the properties of $T = Q \circ (\text{Id} - \gamma \nabla f)$. Suppose that $T$ is $\alpha$-averaged with $\alpha \in [0, 1]$, and that $S = \text{Fix} T \neq \emptyset$. Then it follows from Theorem 37 that, if $(\lambda_n)_{n \in \mathbb{N}}$ is an $\alpha$-relaxation sequence, then $(x_n)_{n \in \mathbb{N}}$ converges to a point in $S$.

Algorithm 95 (PnP Douglas-Rachford) Let $f : \Gamma_0(\mathcal{H})$, let $Q : \mathcal{H} \to \mathcal{H}$, let $\gamma \in ]0, +\infty[$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $]0, +\infty[$, and let $x_0 \in \mathcal{H}$. Iterate
\[
\begin{align*}
\text{for } n = 0, 1, \ldots \\
x_n &= \text{prox}_{\gamma f} y_n \\
y_{n+1} &= y_n + \lambda_n (Q (2x_n - y_n) - x_n).
\end{align*}
\]

In view of (187),
\[
(\forall n \in \mathbb{N}) \quad y_{n+1} = \left(1 - \frac{\lambda_n}{2}\right) y_n + \frac{\lambda_n}{2} T y_n, \tag{188}
\]

where $T = (2Q - \text{Id}) \circ (2\text{prox}_{\gamma f} - \text{Id})$. Now assume that $Q$ is such that $T$ is $\alpha$-averaged for some $\alpha \in [0, 1]$ and $\text{Fix} T \neq \emptyset$. Then it follows from Theorem 37 that, if $(\lambda_n/2)_{n \in \mathbb{N}}$ is an $\alpha$-relaxation sequence, then $(y_n)_{n \in \mathbb{N}}$ converges to a point in $\text{Fix} T$ and we deduce that $(x_n)_{n \in \mathbb{N}}$ converges to a point in $S = \text{prox}_{\gamma f}(\text{Fix} T)$. Conditions for $T$ to be a Banach contraction in the two previous algorithms are given in [199].

Applying the Douglas-Rachford algorithm to the dual of Problem 66 leads to a simple form of the alternating direction method of multipliers. Thus, consider algorithm 95, where $f$, $\gamma$, and $Q$ are replaced by $f^*$, $1/\gamma$ and $\text{Id} + \gamma^{-1} Q(-\gamma^*)$, respectively, and $(\forall n \in \mathbb{N}) \lambda_n = 1$. Then we obtain the following algorithm [63], which is applied to image fusion in [215].

Algorithm 96 (PnP ADMM) Let $f \in \Gamma_0(\mathcal{H})$, let $Q : \mathcal{H} \to \mathcal{H}$, let $\gamma \in ]0, +\infty[$, let $y_0 \in \mathcal{H}$, let $z_0 \in \mathcal{H}$, and let $\gamma \in ]0, +\infty[$. Iterate
\[
\begin{align*}
\text{for } n = 0, 1, \ldots \\
x_n &= Q (y_n - z_n) \\
y_{n+1} &= \text{prox}_{\gamma f} (x_n + z_n) \\
z_{n+1} &= z_n + x_n - y_{n+1}.
\end{align*}
\]

Note that, beyond the above fixed point descriptions of $S$, the properties of the solutions in plug-and-play methods are elusive in general.

C. Adjoint mismatch problem

A common inverse problem formulation is to
\[
\begin{align*}
\text{minimize } & f(x) + \frac{1}{2} \| H x - y \|^2 + \frac{\kappa}{2} \| x \|^2, \tag{190}
\end{align*}
\]

where $f \in \Gamma_0(\mathcal{H})$, $y \in \mathcal{G}$ models the observation, $H : \mathcal{H} \to \mathcal{G}$ is a linear operator, and $\kappa \in ]0, +\infty[$. This is a particular case of Problem 66 where
\[
g = \frac{1}{2} \| H \cdot y \|^2 + \frac{\kappa}{2} \| \cdot \|^2, \tag{191}
\]

has Lipschitzian gradient $\nabla g : x \mapsto H^* (H x - y) + \kappa x$. It can therefore be solved via Proposition 70, which therefore requires the application of the adjoint operator $H^*$ at each iteration. Due to both physical and computational limitations in certain applications, this adjoint may be hard to implement and it is replaced by a linear approximation $K : \mathcal{G} \to \mathcal{H}$ [241]. This leads to a surrogate of the proximal-gradient scheme (105) in the form
\[
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \lambda_n \left( \text{prox}_{\gamma f} \left( (1 - \gamma \kappa) x_n - \gamma K (H x_n - y) \right) - x_n \right), \tag{192}
\]

with $\gamma \in ]0, +\infty[$ and $\{ \lambda_n \}_{n \in \mathbb{N}} \subset ]0, 1]$. Let us assume that $L = K \circ H + \kappa \text{Id}$ is a cocoercive operator. Then the above algorithm is an instance of the forward-backward splitting algorithm introduced in Proposition 50 to solve Problem 47 where $A = \partial f$ and $B = L - Ky$. This means that a solution produced by algorithm (192) no longer solves a minimization problem since $L$ is not a gradient in general [19, Proposition 2.58]. However, suppose that $g$ is $\nu$-strongly convex with $\nu \in ]0, +\infty[$, let $\zeta_{\text{min}}$ be the minimum eigenvalue of $L + L^*$, set $\chi = 1/(\nu + \zeta_{\text{min}})$, let $\tilde{x}$ be the solution to Problem 66, and let $\tilde{x}$ be the solution to Problem 47. Then, as shown in [72],
\[
\| \tilde{x} - \tilde{x} \| \leq \chi \| (H^* - K) (H \tilde{x} - y) \|. \tag{193}
\]

Note that a sufficient condition ensuring that $L$ is cocoercive is that $\zeta_{\text{min}} > 0$. The problem of adjoint mismatch when $f = 0$ is studied in [117].
D. Problems with nonlinear observations

We describe the framework presented in [104], [105] to address the problem of recovering an ideal object \( x \in \mathcal{H} \) from linear and nonlinear transformations \( (r_k)_{1 \leq k \leq q} \) of it.

Problem 97 For every \( k \in \{1, \ldots, q\} \), let \( R_k : \mathcal{H} \rightarrow \mathcal{G}_k \) and let \( r_k \in \mathcal{G}_k \). The task is to find \( x \in \mathcal{H} \) such that \( (\forall k \in \{1, \ldots, q\} ) \ R_k x = r_k \).

(194)

In the case when \( q = 2 \), \( \mathcal{G}_1 = \mathcal{G}_2 = \mathcal{H} \), and \( R_1 \) and \( R_2 \) are projectors onto vector subspaces, Problem 97 reduces to the classical linear recovery framework of [236] which can be solved by projection methods. We can also express Problem 61 as a special case of Problem 97 by setting \( m = q \) and

\[ (\forall k \in \{1, \ldots, q\} ) \ r_k = 0 \quad \text{and} \quad R_k = \text{Id} - \text{proj}_{\mathcal{C}_k}. \]

(195)

In the presence of more general nonlinear operators, however, projection techniques are not applicable to solve (194). Furthermore, standard minimization approaches such as minimizing the least-squares residual \( \sum_{k=1}^{q} \| R_k x - r_k \|_2^2 \) typically lead to an intractable nonconvex problem. Yet, we can employ fixed point arguments to approach the problem and design a provably convergent method to solve it. To this end, assume that (194) has a solution and that each operator \( R_k \) is proxifiable in the sense that there exists \( S_k : \mathcal{G}_k \rightarrow \mathcal{H} \) such that

\[ (\forall x \in \mathcal{H} ) \quad S_k (R_k x) = S_k r_k \Rightarrow R_k x = r_k. \]

(196)

Clearly, if \( R_k \) is firmly nonexpansive, e.g., a projection or proximity operator (see Fig. 3), then it is proxifiable with \( S_k = \text{Id} \). Beyond that, many transformations found in data analysis, including discontinuous operations such as wavelet coefficients hard-thresholding, are proxifiable [104], [105]. Now set

\[ (\forall k \in \{1, \ldots, q\} ) \ T_k = S_k R_k + \text{Id} - S_k \circ R_k. \]

(197)

Then the operators \((T_k)_{1 \leq k \leq q}\) are firmly nonexpansive and Problem 97 reduces finding one of their common fixed points. In view of Propositions 18 and 26, this can be achieved by applying Theorem 37 with \( T = T_1 \circ \cdots \circ T_q \). The more sophisticated block-iterative methods of [20], [105] are also applicable.

Let us observe that the above model is based purely on a fixed point formalism which does not involve monotone inclusions or optimization concepts. See [104], [105] for data science applications.

VIII. CONCLUDING REMARKS

We have shown that fixed point strategies provide a convenient and powerful framework to model, analyze, and solve a variety of data science problems. Not only sophisticated convex minimization and game theory problems can be solved reliably with fixed point algorithms but, as illustrated in Section VII, nonlinear models that would appear to be predefined to nonconvex minimization methods can be effectively solved with the fixed point machinery. The prominent role played by averaged operators in the construction of provably convergent fixed point iterative methods has been highlighted. Also emphasized is the fact that monotone operator theory constitutes a very effective modeling tool.

Acknowledgment. The authors thank Minh N. Bui and Zev C. Woodstock for their careful proofreading of the paper.
