**Keywords.** *Bartonella henselae*; culture-negative endocarditis; Ehlers-Danlos syndrome; electrospray ionization mass spectrometry; quantitative PCR.

**CASE REPORT**

A 58-year-old man with Ehlers-Danlos syndrome, an aortic graft, mechanical aortic valve, and mitral valve annuloplasty ring placed 10 years earlier presented to the hospital with 6 weeks of fever, chills, drenching night sweats, epistaxis, and an unintended weight loss of 16 pounds. He reported taking warfarin and aspirin faithfully. He lived on an organic farm and frequently walked barefoot when ploughing soil. He and his wife had 1 monkey, 2 dogs, and 15 cats, some of which were feral; they previously kept and milked goats.

Upon his initial presentation, he was febrile (39.5°C), tachycardic (105 beats/minute), and was noted to have mild epistaxis. His physical exam was also significant for temporal wasting, petechial hemorrhages of the conjunctiva and palate, poor dentition, and splenomegaly. Three sets of blood cultures obtained before starting antibiotics were negative for pathogens. Laboratory values included a white blood cell count of 9.7 × 10³/µL with 80% neutrophils, normal creatinine (1.3 mg/dL), low albumin (3.3 g/dL), elevated C-reactive protein ([CRP] 53 mg/L; normal range, 0–9), and an increased internationalized normal ratio of 5.2 (normal range, 0.85–1.15). In addition, he was anemic with a hemoglobin of 10.4 g/dL and thrombocytopenic with platelets of 100 × 10³/µL.

A transesophageal echocardiogram (TEE) did not reveal any valvular lesions or vegetations. A whole body 18fluorodeoxyglucose-positron emission tomography/computed tomography (18FDG-PET/CT) scan detected abnormal hypermetabolic activity in his graft, extending from the aortic arch into the aortic root/valve prosthesis, as well as his right subclavian artery and spleen (Figure 1). This finding, considered a major criterion for the diagnosis of infective endocarditis, in combination with his persistent fevers and prosthetic valve, both minor criteria, prompted initiation of empiric ceftriaxone and doxycycline for possible infective endocarditis [1]. During his hospital course, the patient developed complications related to anticoagulation and acute kidney injury. Accordingly, we chose to avoid rifampin and gentamicin, until his renal function stabilized.

In order to identify a specific pathogen, we used molecular methods to test deoxyribonucleic acid extracted from whole blood collected in ethylenediaminetetraacetic acid-containing vacutainers (5 mL) and to test antibodies in serum (2 mL) collected on hospital days 2 and 3 [2, 3]. Research-based polymerase chain reaction (PCR)/electrospray ionization mass spectrometry (ESI-MS) detected *Bartonella henselae*, which was confirmed using quantitative PCR targeting the 16S-23S ribonucleic acid intergenic region and Western immunoblotting confirmed this result. This, in turn, permitted early initiation of pathogen-directed therapy and subsequent successful medical management of *B henselae* prosthetic valve endocarditis and aortic graft infection.

DISCUSSION

In this patient with an aortic graft infection and prosthetic valve endocarditis, molecular diagnostic tests on peripheral blood permitted rapid and noninvasive identification of \textit{B. henselae}, prompt initiation of an appropriate antibiotic regimen, and avoidance of surgery. To our knowledge, this is the first report of an aortic graft infection with \textit{B. henselae}. Although the TEE did not detect vegetations, the \textsuperscript{18}FDG-PET/CT scan confirmed our clinical suspicion of prosthetic valve endocarditis and graft infection \cite{1, 7}. Most aortic graft infections \cite{8} and almost all cases of \textit{B. henselae} prosthetic valve endocarditis require surgical intervention \cite{9–14}. One previous report describes using a 30-month course of antibiotics to cure in a woman with prosthetic valve endocarditis due to \textit{B. henselae} \cite{6}. The authors used serology to both identify the pathogen and to monitor the patient’s response to treatment.

Given the number of uncommon pets, our patient had the potential for exposure to several zoonotic pathogens. Three distinct molecular assays identified the pathogen as \textit{B. henselae}. Polymerase chain reaction/ESI-MS offers the advantage of a rapid molecular test that offers sensitive and specific identification of pathogens. Quantitative PCR on the 16S-23S intergenic region and Western immunoblots enabled specific identification among \textit{Bartonella} spp \cite{4}. During his hospitalization, the patient reported that 2 of the cats had recently died, raising the possibility that one of them may have been the source of his \textit{B. henselae} infection \cite{15}.

CONCLUSIONS

In our patient with aortic graft infection and prosthetic valve endocarditis caused by \textit{B. henselae}, rapid molecular testing on blood samples permitted early initiation of pathogen-specific antimicrobial therapy, which helped obviate the need for surgical intervention.
