Abstract. The present study examined the potential function and underlying mechanisms of microRNA-125a (miR-125a) in thyroiditis. Mice were subcutaneously administered with 100 µg porcine thyroglobulin weekly for 2 weeks to establish the thyroiditis model. Results of the in vivo study demonstrated that miR-125a serum expression was upregulated in thyroiditis mice compared with the control group. In vitro studies were performed on a mouse macrophage cell line in which a model of thyroiditis was established using 10 ng/ml human interferon-γ. Uregulated miR-125a expression was achieved via mimic transfection. Increased miR-125a expression reduced autophagy and cell proliferation, increased the apoptotic rate and the expression of pro-inflammatory factors tumor necrosis factor-α, interleukin (IL)-1β, IL-6 and IL-18 via downregulation of the phosphoinositide 3-kinase/protein kinase B/mammalian target of rapamycin (PI3K/Akt/mTOR) signaling pathway. PI3K inhibition enhanced the ability of miR-125a to increase the inflammatory response in vitro via regulation of the PI3K/Akt/mTOR signaling pathway. These results suggest miR-125a inhibited autophagy in a model of thyroiditis through the PI3K/Akt/mTOR signaling pathway.

Introduction

Autoimmune thyroid disease is a common chronic lymphocytic inflammatory disease, which does not exhibit any of the typical symptoms of systemic infection (1), in which thyroid function is progressively reduced, which severely affects the quality of life of patients (2). Hashimoto's thyroiditis (HT) is a common tissue-specific autoimmune thyroid disease. This can be induced by the termination of immune tolerance due to abnormal immune system regulation, as well as an inappropriate autoimmune response against the thyroid (3).

Autophagy is a highly conserved physiological process that involves lysosome-mediated self-digestion and the recycling of intracellular components, including the cell membrane and organelles, particularly mitochondria, cytoskeletal components and protein complexes (4). Autophagy can remove injured or aging biological macromolecules and organelles in cytoplasm, thus maintaining protein turnover and intracellular homeostasis, as well as regulating cell survival, differentiation and development (5). Autophagy is a regulatory stress response that participates in multiple physiological and pathological cell processes, including embryonic development, aging and cancer (5). It is maintained at a basic level in resting cells for the elimination of defective organelles and misfolded proteins, the prevention of excessive protein accumulation and to cope with endoplasmic reticulum stress (6). Additionally, autophagy is an important inflammatory regulator that is associated with inflammasome and cytokine elimination (6). Autophagy maintains cell homeostasis, protecting cells from injury and death (4). Therefore, autophagy is a necessary physiological process for normal cell function and survival.

A study has demonstrated that the phosphoinositide 3-kinase/protein kinase B/mechanistic target of rapamycin (PI3K/Akt/mTOR) signalling pathway can regulate autophagy as well as apoptosis (7). PI3K/Akt controls cell function by regulating the expression of numerous downstream molecules, including Mtor (7). mTOR is a serine/threonine kinase in the phosphatidylinositol 3'kinase-related kinase family that is associated with the proliferation and growth of non-neuronal cells (8). Neurons are non-proliferative cells, but previous research has indicated that neuron size is associated with mTOR regulation (9). It has also been demonstrated that mTOR activation is required for neuron extension direction, dendritic development and spine shape (8). PI3K/Akt signalling pathway activation regulates mTOR protein expression to result in the inhibition of neuronal apoptosis (9). Phosphorylated Akt can activate mTOR and mTOR inhibits downstream molecule ULK1 complex to negatively regulate autophagy (10).

miRNAs have the potential to regulate the expression of the majority of human genes (11). miRNAs participate in biological
processes of autoimmune disease by regulating the development, differentiation, maturation and signal transduction of immune cells (11). Furthermore, they have an important role in maintaining immune cell homeostasis and normal cell function regulation and therefore have the potential to be used in novel disease therapies (12). It has been identified that >100 miRNAs may contribute to autoimmune disease. These miRNAs have the potential to influence the development and function of innate and acquired immune cells (12). Li and Ding (13) recently demonstrated that miR-125a also promoted serum pro-inflammatory cytokine expression in patients with lupus nephritis. In the present study, the function and underlying mechanisms of miR-125a in thyroiditis were examined.

Materials and methods

**Mice and cell culture.** Female 6-week-old C57BL/6 mice (n=12; 18-20 g) were purchased from Chongqing Medical University (Chongqing, China), housed in a clean-grade animal breeding centre at 20-24°C, humidity of 55-60% and were given free access to food and water in a 12 h alternating dark/light cycle. Mice were divided into the control (n=6) and thyroiditis model (n=6) groups. In the thyroiditis model group, mice were subcutaneously injected with 100 µg/ml porcine thyroglobulin (Sigma-Aldrich; Merck KGaA, Darmstadt, Germany) weekly for 2 weeks. The peripheral blood of mice (100 µl) was subsequently collected into centrifuge tubes containing heparin (Sigma-Aldrich; Merck KGaA) under anaesthesia, and then the mice were sacrificed by decapitation. In control group, mice were subcutaneously injected with normal saline once a week. The use of animals in the present study was reviewed and approved by the Ethics Committee of The Zhongshan District of Chongqing General Hospital (Chongqing, China).

The mouse macrophage cell line RAW264.7 cell was obtained from The Type Culture Collection of the Chinese Academy of Sciences (Shanghai, China) and cultured in Dulbecco's modified Eagle's medium (DMEM; Thermo Fisher Scientific, Inc., Waltham, MA, USA) supplemented with 10% fetal bovine serum (FBS; Thermo Fisher Scientific, Inc.), 100 U/ml penicillin and 100 U/ml streptomycin at 37°C and 5% CO2.

**Hematoxylin and eosin (H&E) staining.** Following the induction of thyroiditis, thyroid tissue was fixed with 4% paraformaldehyde for 24 h at room temperature. Thyroid tissue was sectioned into 10-µm-thick sections and H&E staining was performed at room temperature for 10 min. Thyroid tissue was examined using a confocal microscope (Nikon Eclipse Ti; Nikon Corporation, Tokyo, Japan) at a magnification of x100 to confirm the establishment of the model.

**Reverse transcription-quantitative polymerase chain reaction (RT-qPCR).** Total RNA was extracted from the mouse peripheral blood using TRIzol reagent (Life Technologies; Thermo Fisher Scientific, Inc.). cDNA was reverse transcribed using the miScript II RT kit (Qiagen China Co., Ltd., Shanghai, China). RT-qPCR was performed in triplicate using the miScript SYBR Green PCR kit (Qiagen China Co., Ltd.) with the StepOnePlus PCR system (Applied Biosystems; Thermo Fisher Scientific, Inc.). Initial denaturation was performed at 95°C for 30 sec, followed by 40 cycles at 95°C for 30 sec, 60°C for 30 sec and 72°C for 30 sec. The primer sequences used were as follows: miRNA-125a: Forward, 5'-CTGAACAGT TGTGCACGGAAACACTCAGGG-3' and reverse, 5'-CTG AAAGCTTGGAGTGACAGATCTGTGTCCTC-3'; U6: Forward, 5'-CGCGGGCGCCGAGGGCC-3' and reverse, 5'-ATATGGAACGGTTCAGAATT-3'. The expression of miRNA-125a was quantified using the 2^-∆∆CT method (14,15).

**Cell transfection and establishment of an in vitro model of thyroiditis.** Cells (5x10^4) were seeded into 6-well plates, and transfected with 100 ng miR-125a (5'-ACAGUGAGGU CUUGGGGAGGC-3') or a combination of miR-125a and a PI3K inhibitor (20 nM LY294002) for 36 h at 37°C using Lipofectamine® 2000 (both Invitrogen; Thermo Fisher Scientific, Inc.) according to the manufacturer's protocol. In control group, cells (5x10^4) were transfected with 100 ng negative control miRNA (5'-CCCCCCCCCCCCCCCCCCCC CCC-3') using Lipofectamine® 2000 according to the manufacturer's protocol. Cells were subsequently seeded into 6 (1x10^5 cell/well) or 96 (1x10^4 cell/well) well plates in DMEM and stimulated with human interferon-γ (IFN-γ; 10 ng/ml; Sigma-Aldrich; Merck KGaA) for 12 h at 37°C. RAW264.7 cells were cultured with IFN-γ to establish the *in vitro* model of experimental autoimmune inflammation (16).

**MTT assay.** Cells (1x10^5/well) were plated in 96-well plates and MTT (5 mg/ml; 20 µl; Thermo Fisher Scientific, Inc.) was added into each well for 4 h at 37°C. Dimethyl sulfoxide (150 µl; Thermo Fisher Scientific, Inc.) was subsequently added into the wells for 20 min at 37°C. Optical density values were measured with an automatic microplate reader (BioTek Instruments, Inc., Winooski, VT, USA) at 492 nm.

**Flow cytometry.** After 4 h of transfection, cells were plated in 6-well plates (1x10^5/well) in DMEM with 10% FBS for 48 h at 37°C and subsequently washed with PBS. Cells were resuspended in binding buffer (Nanjing KeyGen Biotech Co., Ltd., Nanjing, China) and stained with annexin-V fluorescein isothiocyanate (5 µl) and propidium iodide (5 µl; KeyGen Biotech Co., Ltd.) for 15 min in the dark at room temperature. Samples were analysed using a Beckman Coulter flow cytometer (Beckman Coulter, Inc., Fullerton, CA, USA) and FlowJo software (version 7.6.1; FlowJo LLC, Ashland, OR, USA).

**Immunocytochemical analysis of autophagy.** Cells were washed with PBS, fixed with 4% paraformaldehyde for 15 min at room temperature and permeabilized with 0.1% Triton X-100 for 15 min at room temperature. Cells were subsequently incubated with anti-microtubule-associated protein 1a/1β-light chain 3 (LC3) antibody (cat. no. 3868; 1:1,000; CST Biological Reagents Co., Ltd., Shanghai, China) for 1 h at room temperature, followed by incubation with Alexa Fluor® 488-conjugated goat anti-rabbit antibody (cat. no. 4412; 1:2,000, CST Biological Reagents Co., Ltd.) for 1 h at room temperature. Fluorescence was visualized with a confocal laser-scanning microscope (Zeiss GmbH, Jena, Germany) at a magnification of x20.
miR-125a serum expression increases in a mouse model of thyroiditis. RT-qPCR was performed to detect miR-125a serum expression. miR-125a expression was significantly upregulated in thyroiditis mice, compared with the control group (Fig. 1). This suggests that miR-125a may be associated with the pathophysiology of thyroiditis.

miR-125a upregulation induces apoptosis and reduces cell proliferation in vitro. The effect of miR-125a on cell growth in an in vitro thyroiditis model was examined. miR-125a was significantly upregulated in miRNA-125a mimic transfected cells (Fig. 2A). The upregulation of miRNA-125a significantly increased the apoptotic rate (Fig. 2B) and reduced cell proliferation (Fig. 2C) compared with the control group.

miR-125a upregulation induces the expression of pro-inflammatory factors in vitro. Levels of TNF-α, IL-1β, IL-6 and IL-18 were significantly increased in the in vitro model of thyroiditis when transfected with miR-125a mimics, compared with the control group (Fig. 3), indicating that miR-125a may regulate pro-inflammatory factor expression in thyroiditis.

miR-125a upregulation reduces autophagy in vitro. The effect of miR-125a on the expression of autophagy-associated proteins was investigated. The expression of autophagy proteins LC3 and Atg 5 was significantly decreased in the miR-125a mimic transfected group compared with the control (Fig. 4), suggesting that miR-125a may reduce autophagy in thyroiditis.

miR-125a suppresses PI3K/Akt/mTOR signalling pathway activation in vitro. miR-125a upregulation significantly suppressed PI3K, p-Akt and p-mTOR levels, compared with the control group (Fig. 5), suggesting that miR-125a suppressed autophagy through inhibition of the PI3K/Akt/mTOR signaling pathway.

PI3K inhibition enhances the miRNA-125a-mediated suppression of the PI3K/Akt/mTOR signalling pathway, induction of apoptosis and inhibition of cell proliferation in vitro. To examine the role of PI3K in the function of miRNA-125a in thyroiditis, a PI3K inhibitor, 20 nM of LY294002 was used to inhibit the PI3K/Akt/mTOR signalling pathway in the in vitro thyroiditis model. PI3K inhibitor and miRNA-125a mimics significantly reduced PI3K, p-Akt and p-mTOR levels by miRNA-125a, compared with the miRNA-125a mimic alone (Fig. 6). Apoptotic rate was also significantly increased and cell proliferation was further decreased by the PI3K inhibitor and miRNA-125a mimic, compared with the miRNA-125a mimic alone (Fig. 7).

PI3K inhibition enhances the miRNA-125a-mediated increase in pro-inflammatory mediators and decrease in autophagy in vitro. The inhibition of PI3K in combination with the miRNA-125a mimics significantly increased TNF-α, IL-1β, IL-6 and IL-18 expression compared with miRNA-125a mimic alone (Fig. 8). PI3K inhibition also resulted in a further decrease in LC3 and Atg 5 protein expression thyroiditis, compared with miRNA-125a mimic alone (Fig. 9).

Discussion

HT, also referred to as chronic lymphocytic thyroiditis, is a T-cell-mediated organ specific autoimmune disease (17). It is the most common type of thyroiditis and typically develops in middle-aged women, with the population morbidity at 2% (18). The present study revealed that miR-125a serum expression was upregulated in a mouse model of thyroiditis compared with the control group. However, only 12 mice were used in the current study and larger cohorts should be used in future research to validate this result. In the current study, RAW264.7 cells stimulated with IFN-γ were used to establish the in vitro model of experimental autoimmune inflammation, however they were not uses as a model of experimental autoimmune thyroiditis as that hypothesis was not adequately supported by previous studies. Other experiment models will be used in a further study.

It has previously been indicated that lymphocytic inflammatory disorder is a major source of ROS (17). Excessive ROS production is associated with allergic dermatitis, continuous inflammation, lupus erythematous and multiple dermatis (19). Autophagy defects have been identified in many...

diseases and are associated with an increased susceptibility to autoimmune and inflammatory disease development (20). HT is an autoimmune inflammatory disease and autophagy has an important role in its pathogenesis (20). The present study demonstrated that miR-125a upregulation reduced the expression of autophagy proteins LC3 and Atg in vitro.

Kim et al (21) recently reported that miR-125a inhibits autophagy activation during mycobacterial infection. The
development of HT is closely associated with a signalling network of cytokines, neurotransmitters and other endocrine hormones in the thyroid (22). This signalling network can regulate the differentiation and growth function of thyroid cells in an autocrine and paracrine manner. Inflammatory cytokines associated with this disease include monocyte chemoattractant protein 1 and TNF-α (23). The present study identified that the upregulation of miR-125a induced

the expression of inflammatory factors IL-18, IL-6, IL-1β and TNF-α in vitro. Li et al (13) recently demonstrated that miR-125a also promotes serum pro-inflammatory cytokine expression in patients with lupus nephritis.

Akt is a serine/threonine kinase that regulates cell function by phosphorylating various enzymes, kinases and transcription factors following its activation (24). For example, activated Akt can phosphorylate B cell lymphoma-1 and caspases to inhibit apoptosis and act on the class O forkhead box transcription factors member and nuclear factor-κB to regulate cell survival (25). The PI3K/Akt signalling pathway is a molecular pathway that is required for cell survival and has important roles in apoptosis and tumor genesis (25). Its regulatory effect on downstream autophagy-related molecules, including mTOR, has been extensively recognized (9). The results of the present study revealed that miR-125a upregulation suppressed PI3K/Akt signalling pathway activation in vitro.

It is well established that necrosis can induce the inflammatory response, the release of toxic cytokines and
peripheral cell injury (7). By contrast, apoptosis is a process of programmed cell death that does not induce an inflammatory response and is therefore neuroprotective (10). Research has confirmed that autophagy is regulated by the PI3K/Akt signalling pathway following neuronal mechanical injury. The PI3K/Akt/mTOR pathway has a critical role in the growth, proliferation and survival of cells (10). However, some research has demonstrated that this pathway can induce cell death, particularly necrosis. PI3K/Akt/mTOR pathway activation can inhibit autophagy, which may lead to an increase in necrotic cells and a decrease in neuronal apoptosis and overall cellular activity (9). The present study indicated that the inhibition of PI3K enhanced the ability of miRNA-125a to increase the inflammatory response in macrophages via the PI3K/Akt/mTOR signalling pathway. Tang et al (26) identified that miR-125a also inhibits the invasive ability of hepatocellular carcinoma cells via regulation of the PI3K/Akt/mTOR signalling pathway.

In conclusion, miR-125a increased inflammation and inhibited autophagy in an in vitro model of thyroiditis through regulation of the PI3K/Akt/mTOR signalling pathway. Further investigation is required to fully elucidate the mechanisms involved in autoimmune thyroiditis. The present study provides evidence for a potential mechanism involved in autoimmune thyroiditis pathophysiology.
