THE LOCAL GROMOV–WITTEN THEORY OF $\mathbb{CP}^1$ AND INTEGRABLE HIERARCHIES

ANDREA BRINI

Abstract. In this paper we begin the study of the relationship between the local Gromov–Witten theory of Calabi–Yau rank two bundles over the projective line and the theory of integrable hierarchies. We first of all construct explicitly, in a large number of cases, the Hamiltonian dispersionless hierarchies that govern the full-descendent genus zero theory. Our main tool is the application of Dubrovin’s formalism, based on associativity equations, to the known results on the genus zero theory from local mirror symmetry and localization. The hierarchies we find are apparently new, with the exception of the resolved conifold $\mathbb{C}P^1(-1) \oplus \mathbb{C}P^1(-1)$ in the equivariantly Calabi–Yau case. For this example the relevant dispersionless system turns out to be related to the long-wave limit of the Ablowitz–Ladik lattice. This identification provides us with a complete procedure to reconstruct the dispersive hierarchy which should conjecturally be related to the higher genus theory of the resolved conifold. We give a complete proof of this conjecture for genus $g \leq 1$; our methods are based on establishing, analogously to the case of KdV, a “quasi-triviality” property for the Ablowitz–Ladik hierarchy at the leading order of the dispersive expansion. We furthermore provide compelling evidence in favour of the resolved conifold/Ablowitz–Ladik correspondence at higher genus by testing it successfully in the primary sector for $g = 2$.

1. Introduction

1.1. Gromov–Witten invariants and integrable hierarchies. Gromov–Witten theory deals with the study and the computation of intersection numbers on moduli spaces of holomorphic maps from a source Riemann surface to a compact Kähler manifold $X$. Denote by $\mathcal{M}_{g,n}(X,\beta)$ the Kontsevich compactification of the moduli space of degree $\beta \in H_2(X,\mathbb{Z})$ stable maps from $n$-pointed genus $g$ curves to $X$. The Gromov–Witten invariants of $X$ are defined as

$$
\langle \tau_{p_1}(\phi_{\alpha_1}) \cdots \tau_{p_n}(\phi_{\alpha_n}) \rangle^X_{g,n,\beta} := \int_{[\overline{\mathcal{M}}_{g,n}(X,\beta)]^{vir}} \prod_{i=1}^{n} \mathrm{ev}_i^*(\phi_{\alpha_i}) \psi_i^{p_i},
$$

where $[\overline{\mathcal{M}}_{g,n}(X,\beta)]^{vir}$ is the virtual fundamental class of $\overline{\mathcal{M}}_{g,n}(X,\beta)$, $\phi_{\alpha_i} \in H^*(X,\mathbb{C})$ are arbitrary co-homology classes of $X$, $\mathrm{ev}_i : \overline{\mathcal{M}}_{g,n}(X,\beta) \to X$ is the evaluation map at the $i$th marked point, and $\psi_i = c_i(L_i)$ are the first Chern classes of the universal cotangent line bundles $L_i$ on $\overline{\mathcal{M}}_{g,n}(X,\beta)$. When $p_i = 0$ for all $i$, these invariants have an interpretation as a “count” (in a suitable sense) of holomorphic curves of genus $g$ and degree $\beta$ inside $X$, subject to the constraint of intersecting $n$ generic cycles given by the Poincaré duals of the classes $\phi_{\alpha_i}$.

We know from examples [36,45,54], and have limited general evidence both in the Fano and the Calabi–Yau case [6,21,29,49], that Gromov–Witten invariants of a target space $X$ could be subject to a mysterious web of constraints relating them to one another, and a long-standing problem in the subject has been to lift at least part of the mystery. An influential conjecture stemming from Witten’s influential work on two-dimensional topological gravity [53] asserts that a full explanation should be provided by the theory of integrable hierarchies of non-linear PDEs. More precisely, introduce formal symbols $\epsilon$ and $t^{a,p}$, where $\alpha \in \{1, \ldots, h_X\}$, $h_X := \dim_{\mathbb{C}} H^*(X,\mathbb{C})$ and $p \in \mathbb{N}$; the set $\{t^{a,p}\}_{\alpha \in \{1, \ldots, h_X\}, p \in \mathbb{N}}$ will be short-handly written as $t$. Moreover let $\phi_1$ correspond to the unity of $H^*(X)$ and denote the formal variable $t^{1,0}$ with $x$. We define the all-genus, full-descendent Gromov–Witten potential of $X$ as the formal power series

$$
\mathcal{F}^X(\epsilon, t) = \sum_{g \geq 0} \epsilon^{2g-2} \sum_{\beta \in H_2(X,\mathbb{Z})} \sum_{n \geq 0} \frac{\prod_{i=1}^{n} t^{a_i,p_i}}{n!} \langle \tau_{p_1}(\phi_{\alpha_1}) \cdots \tau_{p_n}(\phi_{\alpha_n}) \rangle^X_{g,n,\beta}.
$$

The Gromov–Witten/Integrable Systems correspondence can then be stated as follows:

**Conjecture 1.1.** Let $\mathcal{F}^X(\epsilon, t)$ denote the all-genus full descendent Gromov–Witten potential of $X$. Then there exists a Hamiltonian integrable hierarchy of PDEs such that $\epsilon^2 \mathcal{F}^X(\epsilon, t)$ is the logarithm of a $\tau$-function associated to one of its solutions. The variables $t^{a,p}$ are identified with times of the hierarchy, and the genus counting variable $\epsilon$ with a perturbative parameter in a small dispersion expansion of the equations.

By “small dispersion expansion” we mean that, in terms of the basic fields $u_\alpha(t)$

$$
u_\alpha(t) := \epsilon^2 \frac{\partial^2 \mathcal{F}^X(\epsilon, t)}{\partial x^2 \partial \epsilon^{a,0}},
$$

the equations of the hierarchy should take the form of a formal gradient expansion

$$
\frac{\partial u_\alpha}{\partial b^{a,p}} = \sum_{g=0}^\infty \sum_{\beta=1}^{h_X} A^{[g]}(u, u_x, u_{xx}, \ldots, u^{(2g+1)}).
$$

In [H] $A^{[g]}$ are degree $2g + 1$ homogeneous polynomials in $u^{(n)}$, where we have defined

$$
\deg \frac{\partial^2 u_\alpha}{\partial x^{2n}} = n \quad \forall \alpha.
$$
A constructive proof of this conjecture - i.e., an explicit characterization of the hierarchy associated to the Gromov–Witten theory of a given target space $X$ - would be a far-reaching result, both in principle and computationally. However, to find out whether such an integrable structure can be found and effectively described is in general a tough task, and the catalogue of rigorous and complete answers to this question is restricted to a discouragingly low number of examples:

(1) $X = \text{pt}$, that is, intersection theory on the Deligne–Mumford compactification of the moduli space of curves. The Witten–Kontsevich theorem states $[36, 54]$ that the KdV hierarchy is the relevant integrable system in this case;

(2) $X = \mathbb{P}^1$, in which case the associated system is the extended Toda hierarchy $[20, 22, 44, 45, 48]$;

(3) $X = (\mathbb{P}^1)^\mathbb{T} \cong \mathbb{C}^*$, where $\mathbb{T}$ is the canonical torus action on $\mathbb{P}^1$. The relevant hierarchy is a reduction of 2D-Toda $[28, 46, 48]$.

For each of the three cases above, a few proposals have been made to extend the correspondence to orbifolds of the form $[X/G]$, where $G$ is a finite group $[32, 33, 47, 51]$; the corresponding candidate hierarchies should be reductions of KP (resp. 2D-Toda) for $X = \text{pt}$ (resp. $X = \mathbb{P}^1$). Unfortunately, apart from this very limited bestiary, the goal to have a general constructive proof of Conjecture 1.1 appears to be out of reach at the moment. In fact, even adding new examples to the above list seems to be a very challenging problem: the next-to-simplest case of the complex projective plane $\mathbb{P}^2$ is already hard to tackle, and it is as of today unsolved.

On the other hand, recent developments $[3, 4]$ strongly indicate a natural new arena to push forward the study of the Gromov–Witten/Integrable Systems correspondence: the local theory of toric Calabi–Yau threefolds. In this context, physics-inspired dualities have provided an impressive quantity of new insights, including conjectural proposals for the solutions of the non-equivariant theory $[4, 7]$ and remarkable connections to other areas of Mathematics: examples include other moduli space problems in Algebraic Geometry $[42, 43]$ and quite different subjects like quantum topology $[31, 40, 50]$ and modular forms $[2]$. On one hand, it is natural to speculate that the high degree of solvability of the theory could be explained by underlying integrable structures; on the other, such a rich web of mathematical interconnections renders the possibility to elucidate the role of integrability in this context an even more appealing goal.

1.2. Main results. In this paper we begin to address this problem by studying the integrable structures that govern the equivariant Gromov–Witten theory of Calabi–Yau rank two bundles over the complex projective line - that is, differential neighbourhoods of a (not necessarily isolated) rational curve inside a Calabi–Yau threefold. By Grothendieck’s theorem, such bundles split into a sum of line bundles: $\mathcal{O}_{\mathbb{P}^1}(n_1) \oplus \mathcal{O}_{\mathbb{P}^1}(n_2)$, $n_i \in \mathbb{Z}$; by the Calabi–Yau condition, we must have that $k := -n_1 = n_2 + 2$. We will denote by $X_k$ the total spaces of these bundles. Moreover, we will consider their equivariant Gromov–Witten theory with respect to a $T \cong \mathbb{C}^*$ torus action, which covers the trivial action on the base $\mathbb{P}^1$ and rotates the fibers:

$$X_k := \mathcal{O}_{\mathbb{P}^1}(-k) \oplus \mathcal{O}_{\mathbb{P}^1}(k - 2)^\mathbb{T}, \quad k \in \mathbb{Z}. \quad (6)$$

In many cases, we will take $T$ to act with identical (resp. opposite) characters on the two fibers; we will refer to these choices as the diagonal (resp. anti-diagonal) case.

In spirit, our study will be very close to the perturbative philosophy of Dubrovin–Zhang $[19]$ for the non-equivariant Gromov–Witten theory of Fano manifolds with $(p, p)$
co-homology. Let us briefly recall the main lines of their strategy. In their case, the whole hierarchy is constructed according to the following two-step process:

(1) find a closed form description of its genus zero approximation (the Principal Hierarchy);

(2) find a reconstruction procedure to incorporate the higher genus corrections.

Step (1) is based on the datum of a Frobenius manifold, that is, a solution of the Witten–Dijkgraaf–Verlinde–Verlinde equations possessing a distinguished dependence on one of its variables (the unity direction) and obeying a quasi-homogeneity condition (existence of the Euler field). Out of these data, it was shown in [15] how to associate a quasi-linear, non-dispersive Hamiltonian hierarchy and a $\tau$-function coinciding with the genus zero Gromov–Witten partition function. Step (2) is much more involved, and strongly relies on the existence of a local bi-Hamiltonian structure, as well as on the assumption of semi-simplicity of the quantum product and of Virasoro constraints on the dispersionful $\tau$-function [18, 19].

We will try to transfer some of the guiding principles of [19] to the case at hand. A major obstacle is the fact that equivariant quantum co-homology rings do not satisfy all axioms of a Frobenius manifold, and in particular the quasi-conformality of the prepotential. Still, the arguments of [15] show that Step (1) above is almost independent of the presence of an Euler vector field, the only requirement being that the prepotential be known in closed form. In other words, bi-Hamiltonianity is not required to reconstruct the Principal Hierarchy; the existence of a grading operator is only needed to fix completely a canonical basis of flows.

For the case of the local theory of $\mathbb{P}^1$ in the diagonal and anti-diagonal case, and for the resolved conifold with a generic $(\mathbb{C}^*)^2$-fiberwise action, we have complete control on the prepotential both from the $A$-model [10] and the $B$-model side [12]. This will be sufficient for us to construct in a completely explicit way the relevant tree-level hierarchies.

From a geometer’s point of view, however, the real utility of a clear link with integrable hierarchies resides in the possibility to effectively perform Step (2), namely, to give a complete recipe to solve the all-genus, full-descendent theory in terms of a dispersive deformation of the Principal Hierarchy. This would be particularly valuable for the case at hand, where little is known about possible higher genus relations between descendent invariants. For this second step, however, it looks hopeless to generalize the methods of Dubrovin–Zhang for the construction of the dispersive tail, as the validity of some of their key assumptions, like existence of Virasoro symmetries annihilating the $\tau$-function, is unclear, if not in jeopardy in our case.

Still, in one example we can find a way out. It turns out that for the resolved conifold $O_{\mathbb{P}^1}(-1) \oplus O_{\mathbb{P}^1}(-1)$ with anti-diagonal action the Principal Hierarchy coincides with the long-wave limit of the so-called Ablowitz–Ladik lattice [1]. The latter can be regarded as a complexified version of the discretized non-linear Schrödinger hierarchy, and appears as a particular reduction of the 2D-Toda hierarchy. Explicit knowledge of a candidate dispersive integrable model allows us to give a full reconstruction of the dispersive flows. It is tempting to speculate that this particular deformation could be the one that verifies Conjecture 1.1 in this case.

Conjecture 1.2. The all-genus, full descendent Gromov–Witten potential of the resolved conifold $X_1$ in the equivariantly Calabi–Yau case is the logarithm of a $\tau$-function of the Ablowitz–Ladik hierarchy.

\footnote{This represents the prototypical family of target spaces whose big quantum co-homologies satisfy the technical assumptions necessary for Dubrovin and Zhang’s machinery to work, like commutativity and semi-simplicity of the quantum product and a well-defined grading.}
If proven, this statement would add a fourth item to the list we presented in Sec. 1.1. We have various reasons to believe that this conjecture is true. First of all, it was shown in [17] that, for 2-component integrable systems like the ones we consider in this paper, integrability very often breaks down when we turn on dispersive perturbations. This is for example the case of the generalized Fermi–Pasta–Ulam systems, for which the procedure of discretizing space derivatives never preserves involutivity of the flows except for exponential non-linearities (i.e. for the Toda lattice). Having one dispersive integrable candidate is an already fortunate circumstance and, if we trust the statement of Conjecture 1.1, it should be taken very seriously.

The second, and much more cogent piece of evidence that we provide is given by the following

**Theorem 1.3.** Conjecture 1.2 is true for $g \leq 1$.

The key idea in our proof will be to establish a so-called “quasi-triviality” property for the Ablowitz–Ladik hierarchy at the leading order of the dispersive expansion. Although differing in the way we obtained it, due to the apparent absence of a second compatible local Poisson bracket for the Ablowitz–Ladik system, our final result comes very close to analogous statements in the bi-Hamiltonian case [18, 19]. Finally, we will exploit the possibility to reconstruct the dispersive flows, order by order in the parameter $\epsilon$, to give higher genus tests of our proposal. In particular we verify the following non-trivial implication of Conjecture 1.2:

**Theorem 1.4.** Under Assumption 3.1, let $\mathcal{F}(\epsilon, t)$ be the Ablowitz–Ladik $\tau$-function which reduces for $\epsilon \to 0$ to the topological $\tau$-function of the Principal Hierarchy of $X_1$ with anti-diagonal action. Then its reduction to small phase space at $O(\epsilon^4)$ coincides with the genus 2 primary Gromov–Witten potential of the resolved conifold in the equivariantly Calabi–Yau case, possibly up to the degree zero term.

For the reasons that we have outlined at the end of section 1.1, we believe that this new example of the Gromov–Witten/Integrable Systems correspondence could be a good starting point for new insights in toric Gromov–Witten theory. A partial list of the questions to be answered include the relationship of our hierarchies with the physicists’ open invariants of toric Calabi–Yau threefolds and the Eynard–Orantin recursion [7, 23], a local mirror symmetry description of the hierarchies in the framework of spectral curves and the universal Whitham hierarchy [3, 38], the study of the fate of the Virasoro conjecture [21] in the equivariant case, multi-parameter generalizations (e.g. the “closed topological vertex”), a Kontsevich-like description via random matrix ensembles, and physical applications for the geometric engineering of extended $\mathcal{N} = 2$ $U(1)$ gauge theories [41] in five dimensions. We plan to return on some of these points in the near future.

**Acknowledgements.** It is a pleasure to thank in primis Boris Dubrovin for his many insightful comments and suggestions, that crucially helped us to solve many puzzles in this project. The present work would not have been undertaken without his influence. I am moreover grateful to Vincent Bouchard, Motohico Mulase and Brad Safnuk for inviting me to present part of this material at the AIM workshop “Recursion structures in topological string theory and enumerative geometry” in Palo Alto; I would also like to thank the participants for their valuable comments. I am likewise happy to thank Tom Coates for inviting me to visit Imperial College in November 2009, as well as for his interest, support, and helpful discussions on related subjects. I also benefitted from discussions with Guido Carlet, Renzo Cavalieri and Paolo Rossi.

This work was supported by a post-doc fellowship of the Fonds National Suisse (FNS); partial support from a “Progetto Giovani 2009” grant of the Gruppo Nazionale per la Fisica Matematica (GNFM) is also acknowledged.
2. The genus zero theory of local $\mathbb{P}^1$ and integrable hierarchies

2.1. Hamiltonian integrable hierarchies from associativity equations. In this section we sketchily review the general construction of dispersionless Hamiltonian hierarchies from associativity equations. The details can be found in the original literature on the subject \cite{16,14}; see also \cite{22} for a recent and very readable account of this material.

Let $\mathcal{V}$ be a $n$-dimensional vector space over a field $\mathbb{K}$. We will denote by $\mathcal{N} := \mathcal{L}(S^1, \mathcal{V}) = \{u : S^1 \to \mathcal{V}\}$ the formal loop space of $\mathcal{V}$; the components of the formal maps $u \in \mathcal{N}$ will often be written as $u^\alpha(x)$, where $x \in S^1$ and $\alpha = 1, \ldots, n$. $\mathcal{N}$ carries naturally the structure of a linear space over $\mathbb{K}$; a distinguished subspace of its dual $\mathcal{N}^*$ is given by the so called local functionals

$$F[u] := \int_{S^1} f(x, u, u_x, u_{xx}, \ldots, u^{(k)}, \ldots) dx,$$

where $u^{(k)}$ denotes the $k$th $x$-derivative of $u$. The adjective “local” refers to the fact that we require the density $f$ to be a differential polynomial, i.e., to depend polynomially\(^2\) on $u^{(k)}$ for $k > 0$. The set of local functionals on $\mathcal{N}$ will be called $LF(\mathcal{N})$. We want to define a Hamiltonian infinite dimensional dynamical system on $\mathcal{N}$ via the following data:

- a local Poisson bracket

$$\{u^\alpha(x), u^\beta(y)\} = \sum_{j=0}^{m} a_{j}^{\alpha\beta}(u, u_x, u_{xx}, \ldots, u^{(n)}, \ldots) \delta^{(j)}(x - y),$$

for some integer $m \in \mathbb{N}$ and differential polynomials $a_j^{\alpha\beta}$; we have denoted by $\delta^{(j)}(x - y)$ the $j$th distributional derivative of Dirac’s $\delta$-function. By bilinearity and the functional Leibnitz rule, the Poisson bracket of elements $F, G \in \mathcal{N}$ is

$$\{F, G\} = \int_{S^1 \times S^1} \frac{\delta F}{\delta u^\alpha(x)} \frac{\delta G}{\delta u^\beta(y)} \left\{u^\alpha(x), u^\beta(y)\right\} dxdy.$$

The Poisson structure on $\mathcal{N}$ is said to be of hydrodynamic type if $a_j^{\alpha\beta} = \delta_{j1} n^{\alpha\beta}$ for a constant, symmetric, non-degenerate matrix $n^{\alpha\beta}$;

- Hamiltonian flows on $\mathcal{N}$ generated by Hamiltonians $H[u] \in LF(\mathcal{N})$ via

$$u_t = \{u, H[u]\}.$$ 

\textbf{Definition 2.1.} Let $\{u^\alpha(x), u^\beta(y)\}$ be a hydrodynamic Poisson bracket on $\mathcal{N}$ and $H_{\alpha,p}[u] \in LF(\mathcal{N})$, $\alpha = 1, \ldots, n$, $p \in \mathbb{N}$, be a countably infinite sequence of independent local functionals

$$H_{\alpha,p}[u] = \int_{S^1} h_{\alpha,p}(u(x), u_x(x), \ldots, x) dx.$$

Then:

(1) the equations

$$\frac{\partial u}{\partial t^{\alpha,p}} = \{u, H_{\alpha,p}[u]\}$$

are said to make up a Hamiltonian integrable hierarchy of PDEs if they satisfy the involutivity condition

$$\{H_{\alpha,p}[u], H_{\beta,q}[u]\} = 0 \quad \forall \alpha, \beta, p, q;$$

\textsuperscript{2}In this formal setting and in absence possibly of a well defined analytic theory of functions when $\mathbb{K} \neq \mathbb{C}$ or $\mathbb{R}$, a non-polynomial functional dependence should be thought of as a non-truncating formal power series expansion in $u^\alpha(x)$.
the hierarchy is said to possess a \( \tau \)-structure if there exists a potential \( \partial_x \ln \tau \) for the integrability condition

\[
\partial_{t^\alpha} h_{\alpha, p-1} = \partial_{t^\alpha} h_{\beta, q-1} = \partial_x \partial_{t^\alpha} \partial_{t^\beta} \ln \tau. \quad (14)
\]

\( \tau( u, u_x, u_{xx}, \ldots, u^{(n)} \ldots ) \) is called a \( \tau \)-function of the hierarchy;

(3) the hierarchy is said to be dispersionless if the system \((12)\) is quasi-linear, i.e., if the densities \( h_{\alpha, p} \) do not depend on derivatives \( u^{(k)} \) of the fields for \( k \geq 1 \).

It was suggested by Witten \[54\] that Conjecture 1.1 should have a description in this framework, with the Hamiltonian densities \( h_{\alpha, p} \) being related to 2-point “big phase space” correlators in a topological field theory coupled to gravity. For the genus zero theory this was formalized in fairly large generality, and in a completely explicit way, in the work of Dubrovin \[15, 16\]. We will now review it in the case we will be interested in of the \( T \simeq (\mathbb{C}^*)^k \)-equivariant Gromov–Witten theory of a Kähler target manifold \( X \). We will assume that \( T \) acts with compact fixed loci \( F \).

Take \( \mathcal{V}_X := QH^*(X) \) to be the big equivariant quantum co-homology ring of \( X \); in this case \( \mathbb{K} = \mathbb{C}(\lambda_1, \ldots, \lambda_k) \) is the field of fractions of \( H^*(pt) \). Suppose moreover that \( \mathcal{V}_X^{\text{odd}} = 0 \), and pick a basis \( \phi_\alpha, \alpha = 1, \ldots, h_X \) of \( \mathcal{V}_X \), where \( h_X = \dim \mathcal{V}_X \) and \( \phi_1 = 1_{\mathcal{V}_X} \); a generic element of \( \mathcal{V}_X \) will be written \( u = \sum_\alpha u^\alpha \phi_\alpha \) with \( u^\alpha \in \mathbb{K} \). The genus zero primary Gromov–Witten potential of \( X \) is a formal analytic function \( F_0 : \mathcal{V}_X \to \mathbb{K} \),

\[
F_0(u) = \sum_{j,d=0}^{\infty} \frac{1}{j!} \left( u^1, \ldots, u^m \right)_j \left( 0 \right)_{j,d}^X = \sum_{j=0}^{\infty} \sum_{\alpha_1, \ldots, \alpha_m} f_{\alpha_1, \ldots, \alpha_j} u^{\alpha_1} \ldots u^{\alpha_j}, \quad (15)
\]

satisfying:

1. \( \eta_{\alpha \beta} := \partial_1 \partial_2 F_0(\mathbf{u}) \) is a nondegenerate, constant symmetric matrix;
2. \( F_0 \) obeys the following set of third order, non-linear PDEs

\[
\partial^3_{\alpha \beta \gamma} F_0 \eta^{\gamma \delta} \partial^3_{\delta \epsilon s} F_0 = \partial^3_{\alpha \gamma} F_0 \eta^{\gamma \delta} \partial^3_{\delta \epsilon s} F_0. \quad (16)
\]

It is intended that indices are raised with the non-degenerate contravariant 2-tensor \( \eta^{\alpha \beta} = (\eta^{-1})_{\alpha \beta} \), and we use Einstein’s convention to sum over repeated indices.

**Remark 2.1.** It should be stressed at this point that, as opposed to the usual definition of a Frobenius manifold \[16\], we do not have a quasi-homogeneity condition obeyed by \( F_0 \). This is due to the fact that the ground field \( \mathbb{K} \) has a non-trivial grading in this case, and therefore the natural Euler operator, keeping track of the equivariant de Rham degree, is not \( \mathbb{K} \)-linear.

Eq. \((15)\) implies the following fact. Define the 1-parameter family of connections on \( T^* \mathcal{V}_X \)

\[
D_z := d + \Gamma, \quad (17)
\]

where the Christoffel symbol \( \Gamma_\alpha \) in components reads \( (\Gamma_\alpha)_\beta := z c_{\alpha \beta} \) and \( z \in \mathbb{K} \). Notice that because of integrability of \( c_{\alpha \beta} \gamma \) and \((16)\) we have

\[
D_z^2 = 0 \quad \forall z, \quad (18)
\]

that is, the connection is flat. Its horizontal sections \( \omega^\beta_{\alpha} d\mathbf{u}^\alpha = dh^\beta_{(\beta)} \), where \( \beta = 1, \ldots, h_X \) labels a fundamental set of solutions of \((18)\), should come from a basis \( f^\beta \in \text{Fun}(\mathcal{V}_X) \) of solutions of the holonomic system of PDEs

\[
\partial^2_{\alpha \beta} h^\delta = z c_{\alpha \beta} \partial_\gamma h^\delta, \quad \delta = 1, \ldots, h_X. \quad (19)
\]
We will call the solutions of (19) the flat functions of $V_X$. Their duals $h_\alpha(u, z) := \eta_{\alpha\beta} h^\beta(u, z)$ can always be normalized such that

$$h_\alpha(u, 0) = w_\alpha = \eta_{\alpha\beta} u^\beta, \quad (20)$$

$$\partial_x h_\alpha(u, z) \eta^{\gamma\delta} \partial_x h_\beta(u, -z) = \eta_{\alpha\beta}, \quad (21)$$

$$\partial_t h_\alpha(u, z) = z h_\alpha(u, z) + \eta_{1\alpha}. \quad (22)$$

**Remark 2.2.** Eqs. (20)-22 do not fix completely the ambiguity in the choices of the $z$-dependent constants of integration of (19). In the ordinary Frobenius manifold case such ambiguity could be dealt with by imposing additional conditions coming from the existence of the Euler vector field. In the cases we are interested in such a procedure will have to be performed otherwise (see Sec. 2.2).

Solutions of WDVV relate to the theory of Hamiltonian dispersionless systems in the following way. Endow the loop space $\mathcal{N}^*_X := L(S^1, V_X)$ with the hydrodynamic Poisson bracket

$$\{u^\alpha(x), u^\beta(y)\} = \eta^{\alpha\beta}(x - y). \quad (23)$$

Then the Taylor coefficients of the $z$-expansion of $h_\alpha(\tau; z)$ with respect to $z$,

$$h_\alpha(u, z) := \sum_{z=0}^\infty h_{\alpha,p-1}(u) z^p, \quad (24)$$

define dispersionless Hamiltonian densities on $\mathcal{N}^*_X$. The system of 1st order quasi-linear PDEs

$$\frac{\partial u}{\partial t^{\alpha,p}} = \left\{ u, \int_{S^1} h_{\alpha,p}(u(x)) \right\} dx \quad (25)$$

will be called the **Principal Hierarchy** of $X$. We have the following

**Theorem 2.3** (Dubrovin). The set of Hamiltonians $H_{\alpha,p} = \int_{S^1} h_{\alpha,p} dx$ mutually Poisson-commute with respect to the Poisson bracket (23). Let $u^\alpha(t)$ solve the system (25) with boundary condition

$$u_\alpha(t) \bigg|_{t^{\alpha,p}=0} = \partial_{t^{\alpha,p}} F_0(u^1 + x, u^2, u^3, \ldots, u^n) \quad (26)$$

and define for all times

$$\langle\langle \tau_\rho \phi_\alpha \tau_q \phi_\beta \rangle\rangle_0 = \frac{1}{2\pi i} \oint \frac{dzdw}{z+w} \left( \partial_x h_\alpha(u(t), z) \eta^{\alpha\beta} \partial_x h_\beta(u(t), w) - \eta_{\alpha\beta} \right), \quad (27)$$

$$\partial_{x,p}^2 F_0(x + t^{1,0}, t^{2,0}, \ldots) := \sum_{\beta} \langle\langle \tau_\rho \phi_\alpha \tau_q \phi_\beta \rangle\rangle_0 \langle\langle \tau_\rho \phi_\alpha \tau_q \phi_\beta \rangle\rangle_0 (t) t^{\alpha,p} + \sum_{\beta,q} \langle\langle \tau_\rho \phi_\alpha \tau_q \phi_\beta \rangle\rangle_0 (t) \langle\langle \tau_\rho \phi_\alpha \tau_q \phi_\beta \rangle\rangle_0 (t), \quad (28)$$

$$\langle\langle \phi_\alpha \phi_\beta \phi_\gamma \rangle\rangle_0 := \partial_{\alpha,p} \partial_{\beta,q} \ldots \partial_{\gamma,r} F_0(t). \quad (29)$$

Then $F_0$ is the logarithm of a $\tau$ function for the hierarchy (25). It moreover satisfies

$$F_0 \bigg|_{t^{\alpha,p}=0} = F_0 (t^{\alpha,0}) \quad \text{(reduction to primaries)}$$

$$\partial_x F_0 = \sum_{\beta} t^{\alpha,p} \partial_{\alpha,p-1} F_0 + \frac{1}{2} \eta_{\alpha\beta} t^{\alpha,0} t^{\beta,0} \quad \text{(string equation)} \quad (30)$$

$$\langle\langle \phi_{\alpha,p} \phi_{\beta,q} \phi_{\gamma,r} \rangle\rangle_0 = \langle\langle \phi_{\alpha,p-1} \phi_{\beta,q} \rangle\rangle_0 \eta^{\delta\gamma} \langle\langle \phi_{\delta,e} \phi_{\gamma,f} \phi_{\gamma,g} \rangle\rangle_0 \quad \text{(genus zero TRRs)} \quad (31)$$

For the purpose of the Gromov–Witten/Integrable Systems correspondence this construction has a number of very attractive features, together with a few weak points. The main virtue of this construction is that it does not depend on the details of $X$, apart from the requirement that $\mathcal{V}_X^{\text{odd}} = 0$; moreover, it provides an explicit construction of the integrable hierarchy starting from primary data, thus yielding a constructive proof of Conjecture [11] at the leading order in $\epsilon$ (i.e. in the genus zero subsector). However, to make it work we
need to have control on $F_0$ in closed form - no implicit, recursive or up-to-inversion-of-the-mirror-map form will do the job. Any polynomial truncation of (15) affects dramatically the form of the three-point couplings $c_{a_1\ldots a_3}$ and therefore the flat functions. In other words, we must know explicitly all the coefficients $f_{a_1\ldots a_3}$ in (15). This limitation turns out to be very constraining in the context of ordinary Gromov–Witten theory, where it basically reduces the list of viable examples to the cases of $X = \text{pt}$ and $X = \mathbb{P}^1$ we mentioned in Sec. 1.1. However, since the construction does not depend on the existence of an Euler vector field, we might expect to find new examples in the context of equivariant Gromov–Witten theory. Indeed, as we are going to argue, the local theory of rational curves inside Calabi–Yau threefolds evades this limitation in a large number of cases.

2.2. The resolved conifold. Let us then consider the target spaces $X_k$ of (6). We begin with the rigid case $k = 1$, and consider its equivariant theory with respect to a $T \simeq (\mathbb{C}^*)^2$ fiberwise action rescaling the fibers. Let $H(X_1) := H^*_T(X_1) \simeq H^*(F_1) \otimes \mathbb{C}(\lambda_1, \lambda_2)$ denote the localized $T$-equivariant co-homology of $X_1$ and $F_1 \simeq \mathbb{P}^1$ be the fixed locus of the $T$-action, that is, the null section of $X_1 \to \mathbb{P}^1$. Let moreover $(1, p)$ denote the canonical basis of $H(X_1)$ (regarded as a free $\mathbb{C}(\lambda_1, \lambda_2)$-module), where 1 and $p$ denote respectively the lifts to $T$-equivariant co-homology of the identity and the Kähler class of the base $\mathbb{P}^1$, and write $u := v + wp$, i.e. $v := u^1$, $w := u^2$ with $v, w \in \mathbb{C}(\lambda_1, \lambda_2)$. We separate the degree zero ("classical") and positive degree ("quantum") parts of the genus zero Gromov–Witten potential of $X_1$ as

$$F_0^{X_1}(u) = F_{0,\text{cl}}^{X_1}(u) + F_{0,\text{qu}}^{X_1}(u),$$

where

$$F_{0,\text{cl}}^{X_1}(u) = \frac{1}{3!} \int_{[p]} \frac{u \cup u \cup u}{e(N_{X_1/F_1})},$$

$$F_{0,\text{qu}}^{X_1}(u) = \sum_{d>0} e^{dw} N_{0,d}^{(1)},$$

$$N_{g,d}^{(1)} = \int_{([X_1]_{g,d})^{vir}} 1.$$

A special feature of the $(\mathbb{C}^*)^2$-equivariant theory of the resolved conifold is that the invariants $N_{0,d}^{(1)}$ have a closed expression for all $d$ [12] given by the Aspinwall-Morrison multicovering formula [5]

$$N_{0,d}^{(1)} = \frac{1}{d^3}.$$

$X_1$ then belongs to the list of fortunate cases where a closed form expression for the genus zero Gromov–Witten invariants of all degrees, and therefore for the prepotential, is known in terms of special functions. Explicitly we have

$$F_{0,\text{cl}}^{X_1}(v, w) = \frac{1}{3!} \int_{[p]} \frac{(v + wp)^3}{(\lambda_1 - p)(\lambda_2 - p)}$$

$$= \frac{1}{3! \lambda_1 \lambda_2} \int_{[p]} (v + wp)^3 \left(1 + \left(\frac{1}{\lambda_1} + \frac{1}{\lambda_2}\right)p\right)$$

and hence

$$F_0^{X_1} = \frac{v^3}{3!} \frac{\lambda_1 + \lambda_2}{\lambda_1^2 \lambda_2^2} + \frac{1}{2\lambda_1 \lambda_2} v^2 w + \text{Li}_3(e^w),$$

where we have introduced the polylogarithm function

$$\text{Li}_j(x) = \sum_{n=1}^{\infty} \frac{x^n}{n^j}.$$

This is all that is necessary to apply the machinery of Sec. 2.1. For future use, we state the following
Lemma 2.4. Consider the following solution of WDVV
\[ F_0 = \frac{Pv^3}{3!} + \frac{Qv^2w}{2} + \text{Li}_3(e^w). \] (37)
Then the general integral of the flatness conditions \([19]\) reads
\[ f(v, w, z, P, Q) = A(w, z, P, Q) \frac{e^{vw}}{z} + B(z), \] (38)
where
\[ A(w, z, P, Q) = c_1(z) {}_2F_1 \left( -\Delta_+, -\Delta_-; 1; e^w \right) \]
\[ + c_2(z) {}_2F_1 \left( 1 + \Delta_-, 1 + \Delta_+; \frac{zP}{Q^2} + 2; 1 - e^w \right) \left( 1 - e^w \right)^{\frac{P^2}{Q^2} + 1}, \] (39)
\[ \Delta_\pm = \frac{z \left( P \pm \sqrt{P^2 - 4Q^2} \right)}{2Q^2}. \]

Proof. The form (38) follows from (19) with \(\alpha = v\). Putting \(\alpha = \beta = w\) in (19) yields a Fuchsian ODE for \(A\) as a function of \(w\),
\[ \frac{\partial_w^2 A}{Q} = \frac{z^2 A(w)}{Q} - \frac{Pz \partial_w A(w)}{Q^2}, \] (40)
whose general integral has the form (39). \(\Box\)

For the prepotential (35) we have
\[ \Delta_+ = z \lambda_1, \quad \Delta_- = z \lambda_2, \quad \frac{P}{Q^2} = \lambda_1 + \lambda_2. \] (41)

Let us fix a normalization of the corresponding flat functions \(h^\alpha(v, w; z)\),
\[ h^\alpha(v, w; z) = A^\alpha(w, z, \lambda_1, \lambda_2) \frac{e^{vw}}{z} + B^\alpha(z), \] (42)
in order for the flows to satisfy the string axiom and the genus zero TRRs. Eq. (22) fixes \(B^\alpha(z)\) to be
\[ B^\alpha(z) = -\frac{\delta^{\nu, \alpha}}{z}. \] (43)
To fix completely \(A^\alpha(w, z, \alpha, \beta, \lambda)\) we use the fact that it is related \([13]\) to the fundamental solution \(S_{\alpha \beta}\) of the Gauss-Manin system as
\[ A^\alpha = \partial_\nu h^\alpha \bigg|_{v=0}, \] (44)
\[ \partial_\nu h^\alpha =: S_{0,0}^\alpha =: J^\alpha, \] (45)
that is to say, it corresponds to the \(\alpha\)-component of the \(J\)-function at \(v = 0\). The Coates–Givental theorem \([12]\) prescribes it to take the form
\[ J(v = 0, w, z, \lambda_1, \lambda_2) = e^{vp \log q(w)} \sum_{d \geq 0} \prod_{m=-d+1}^0 (-p + m/z + \lambda_1) (-p + m/z + \lambda_2) \frac{q(w)^d}{\prod_{m=1} (p + m/z)^2}, \] (46)
where \(q(w)\) is the inverse mirror map. We have the following

Proposition 2.5. For the normalized flat functions \([12]\) we have
\[ A^\alpha(w, z, \lambda_1, \lambda_2) = c_1^\alpha (z, \lambda_1, \lambda_2) {}_2F_1 (-z \lambda_1, -z \lambda_2; 1; e^w) \]
\[ + c_2^\alpha (z, \lambda_1, \lambda_2) {}_2F_1 (z \lambda_1 + 1, z \lambda_2 + 1; z(\lambda_1 + \lambda_2) + 2; 1 - e^w) \]
\[ \times \left( 1 - e^w \right)^{\lambda_1 + \lambda_2 + 1}, \] (47)
where:
\[
c_1^v(z, \lambda_1, \lambda_2) = 1,
\]
\[c_2^v(z, \lambda_1, \lambda_2) = 0,
\]
\[c_1^w(z, \lambda_1, \lambda_2) = -z \left[ \psi^{(0)}(z \lambda_1 + 1) + \psi^{(0)}(z \lambda_2 + 1) + 2\gamma \right],
\]
\[c_2^w(z, \lambda_1, \lambda_2) = -\frac{z \Gamma(z \lambda_1 + 1) \Gamma(z \lambda_2 + 1)}{\Gamma(z (\lambda_1 + \lambda_2) + 2)}.
\]

In (50), \(\gamma\) is the Euler-Mascheroni constant, while \(\psi^{(0)}(x)\) is the polygamma function
\[\psi^{(0)}(z) = \frac{d \log \Gamma(z)}{dz}.
\]

**Proof.** The \(O(z)\) term of the expansion of the \(J\)-function is the statement that the mirror map is trivial in this case
\[\log q = w \pmod{2\pi i}.
\]

Let us examine the summand in (46) above more closely, starting from the numerator. The finite product gives, remembering that \(p^2 = 0\),
\[
\prod_{m=-d+1}^{0} (-p + m/z + \lambda_1) (-p + m/z + \lambda_2) = \prod_{m=0}^{d-1} \left[ p \left( \frac{2m}{z} - \lambda_1 - \lambda_2 \right) + \frac{m^2 - z \lambda_1 m - z \lambda_2 m + z^2 \lambda_1 \lambda_2}{z^2} \right] = \left( \frac{z}{2} \right)^{d} \Gamma(d - z \lambda_1) \Gamma(d - z \lambda_2) \frac{\Gamma(z \lambda_1) \Gamma(z \lambda_2)}{\Gamma(-z \lambda_1) \Gamma(-z \lambda_2)} \bigg) p,
\]

while for the inverse of the denominator we obtain simply
\[\frac{1}{\prod_{m=1}^{d} (p + m/z)^2} = \frac{(z^2)^d}{\Gamma(d+1)^2} - 2z \left( \frac{z^2}{2} \right)^d H_d p,
\]

where \(H_d\) is the \(d^{th}\) harmonic number. For the \(v\)-component, this means that we should have
\[A^v(w, z, \lambda_1, \lambda_2) = \sum_{d \geq 0} e^{wd} \frac{\Gamma(d - z \lambda_1) \Gamma(d - z \lambda_2)}{\Gamma(d+1)^2 \Gamma(-z \lambda_1) \Gamma(-z \lambda_2)}.
\]

Comparison with (47) sets
\[c_1^v = 1, \quad c_2^v = 0.
\]

On the other hand, the component \(J^w\) of the \(J\)-function in the direction of the volume form is a series that looks as follows
\[J^w(0, w, z, \lambda_1, \lambda_2) = zw A^v(w, z, \lambda_1, \lambda_2) + \sum_{d \geq 0} \left[ e^{wd} \frac{z \Gamma(d - z \lambda_1) \Gamma(d - z \lambda_2)}{\Gamma(d+1)^2 \Gamma(-z \lambda_1) \Gamma(-z \lambda_2)} \times \left( -2H_d + \sum_{i=1,2} \left( \psi^{(0)}(d - z \lambda_i) - \psi^{(0)}(-z \lambda_i) \right) \right) \right].
\]

The term proportional to \(zw\) term comes from the \(e^{\exp \log q}\) prefactor of the \(I\) function. Let us then fix the coefficients \(c_i^w(z)\) by Taylor-expanding (47) at \(q = \exp w = 0\). We get an
expansion of the form $a \log q + b + o(1)$

$$A^w(w, z, \lambda_1, \lambda_2) = -\frac{c_2^w(z, \lambda_1, \lambda_2) \Gamma(z(\lambda_1 + \lambda_2) + 2)}{\Gamma(z \lambda_1 + 1) \Gamma(z \lambda_2 + 1)} \log(q) - c_1^w(z, \lambda_1, \lambda_2)$$

while from the explicit form of the $J$-function we get

$$A^w(w, z, \lambda_1, \lambda_2) = z \log q + O(q).$$

Matching the logarithmic coefficient gives (51), while the $O(1)$ term yields (50). This completely fixes the form of the deformed flat coordinates; it is straightforward to check that the normalization conditions (20)-(22) are satisfied.

Theorem 2.3 and Proposition 2.5 together complete the construction of the dispersionless Gromov–Witten hierarchy of the resolved conifold. To see what its first flows look like, take the $z$-expansion of the densities (see (167)-(168))

$$h_v(v, w, z, \lambda_1, \lambda_2) = \frac{w \lambda_1 \lambda_2 + v (\lambda_1 + \lambda_2)}{\lambda_1^2 \lambda_2^2} + \frac{1}{\lambda_1^2 \lambda_2^2} \left( \frac{1}{2} (\lambda_1 + \lambda_2) (v^2 + 2 \lambda_1 \lambda_2 L_2 (e^w)) \right)$$

$$+ O(z^2),$$

$$h_w(v, w, z, \lambda_1, \lambda_2) = \frac{v}{\lambda_1 \lambda_2} + \left( \frac{v^2}{2 \lambda_1 \lambda_2} + L_2 (e^w) \right) z + O(z^2).$$

The first two flows are then

$$\frac{\partial v}{\partial t_{1,0}} = v_x, \quad \frac{\partial w}{\partial t_{1,0}} = w_x,$$

$$\frac{\partial v}{\partial t_{2,0}} = \lambda_1 \lambda_2 \frac{e^w w_x}{1 - e^w w_x},$$

$$\frac{\partial w}{\partial t_{2,0}} = v_x - (\lambda_1 + \lambda_2) \frac{e^w w_x}{1 - e^w w_x}.$$

Eliminating $v$ and putting $t := t_{2,0}$ we obtain the non-linear wave equation

$$w_{tt} = \lambda_1 \lambda_2 \left( \frac{e^w w_x}{1 - e^w w_x} \right)_x - (\lambda_1 + \lambda_2) \left( \frac{e^w w_x}{1 - e^w w_x} \right)_t.$$

In Sec. 3.2 we will see how this relates, in one notable case, to known examples in the theory of integrable hierarchies.

2.3. The diagonal action. Let us move on to the general case (0) of $X_k$. In the first place we restrict $T$ to be isomorphic to a one dimensional torus acting diagonally on the two fibers. We adapt, with obvious meaning of symbols, the conventions of Sec. 2.2 for the potentials, the genus zero invariants, and the equivariant co-homology classes of $X_k$, appending an index $k$ and a superscript $di$ (for “diagonal”) whenever necessary.

The choice of a diagonal action is special for two reasons. First, this is the case that corresponds to the invariants defined by Bryan and Pandharipande in [10]. Secondly, it surprisingly turns out to be a subcase of the $(\mathbb{C}^*)^2$-equivariant theory of the resolved.
conifold we treated in the previous section. The quantum tail of the prepotential indeed [12, 26] has for all \( k \) the Aspinwall-Morrison like form

\[
N_{0,d}^{(k,\text{di})} = \frac{1}{d^3}.
\] (68)

On the other hand, the classical piece is given by

\[
F_{0,\text{cl}}^{X_k,\text{di}}(v,w) = \frac{1}{3!} \int_{[P^1]} \frac{(v + w p)^3}{(\lambda - kp)(\lambda + kp - 2p)}
= \frac{1}{3! \lambda^2} \int_{[P^1]} (v + w p)^3 \left( 1 + \frac{2p}{\lambda} \right)
\] (69)

and hence

\[
F_{X_k,\text{di}} = \frac{1}{3} \left( \frac{v}{\lambda} \right)^3 + \frac{1}{2\lambda^3} v^2 w + \text{Li}_3(e^w) \quad \forall k \in \mathbb{Z}.
\] (70)

Therefore, our results in the previous section apply, a fortiori, to the theory with generic \( k \) and \( \lambda_1 = \lambda_2 \).

### 2.4. The anti-diagonal action.

Another case of special interest is given by the reduction to the case of a \( T \simeq \mathbb{C}^* \) fiberwise action with opposite characters on the two fibers. In this case, the equivariant Euler class of \( X_k \) is trivial

\[
e_T(X_k) = 0,
\] (71)

that is, \( X_k \) is equivariantly Calabi–Yau. The notation will follow the same conventions as in the previous two sections, with a superscript \( \text{ad} \) for “anti-diagonal” added whenever needed.

It was conjectured in general for toric Calabi–Yau threefolds, and verified explicitly for the case at hand [10], that the invariants in the equivariantly Calabi–Yau case are the ones that most closely make contact with the physics prediction based on topological open/closed duality. In particular the authors of [10] could prove the following formula, which could be regarded as a specialization to \( X_k \) of the topological vertex formalism of [4]:

**Theorem 2.6** (Bryan-Pandharipande). The fixed-degree \( d > 0 \), all-genus Gromov - Witten potentials of \( X_k^{\text{ad}} \) are given by the following sum over partitions

\[
\sum_{g \geq 0} e^{2g-2} N_{g,d}^{(k,\text{ad})} = (-1)^d(k-1) \sum_{\rho} \left( \frac{\dim Q(\rho)}{d!} \right)^2 Q_{c(\rho)(1-k)}.
\] (72)

In (72), \( \rho \) is a Young diagram (a partition of length \( l(\rho) \)), \( c_\rho \) is its total content, \( Q := e^{i\epsilon} \), \( h(\square) \) is the hooklength of a box in \( \rho \) and

\[
\frac{\dim Q(\rho)}{d!} = \prod_{\square \in \rho} \left( 2 \sin \left( \frac{h(\square) \epsilon}{2} \right) \right)^{-1}.
\] (73)

As we stressed in Sections [12] and [21] a key point in our analysis is the construction of the hierarchy governing the genus zero theory starting from a closed-form solution of WDVV. To see this, we should be able to obtain a closed expression for the all-degree, genus zero invariants starting from (72). This is the content of the next
Proposition 2.7 ([11]). The quantum part $F_{0,qu}^{X_k,ad}(v, w)$ of the $A$-model prepotential of $X_k$ with anti-diagonal action is

$$
F_{0,qu}^{X_k,ad}(v, w) = \frac{2}{3!} \left( \frac{v}{\lambda} \right)^3 - \frac{1}{2} w \left( \frac{v}{\lambda} \right)^2 + F_{0,qu}^{X_k,ad}(w).
$$

(77)

where $n_k = (k-1)^2$.

Eq. (74) is a corollary of (83); the other two expressions were obtained in [11] by an asymptotic analysis in $\epsilon$ of the sum over partitions [10] based on saddle-point techniques for a suitably constructed random matrix model. A mirror symmetry confirmation, based on Birkhoff factorization applied to the Coates–Givental twisted $I$-function, was given in [25].

To complete the computation of the prepotential we just have to add the degree zero contribution. We get

$$
F_{0}^{X_k,ad}(v, w) = \frac{2}{3!} \left( \frac{v}{\lambda} \right)^3 - \frac{1}{2} w \left( \frac{v}{\lambda} \right)^2 + F_{0,qu}^{X_k,ad}(w).
$$

(77)

The case $k = 1$ is obviously a reduction of the case of Sec. 2.2 for $\lambda_1 = -\lambda_2 = \lambda$; inspection shows moreover that the case $k = 2$ coincides with the one of Sec. 2.3 upon sending $F_0 \rightarrow -F_0$.

The situation for $k > 1$ case is instead radically different. A closed form solution for these flat functions seems too hard to obtain; still the Hamiltonian densities $h_{\alpha, p}$ can be computed and normalized, as we have done before, order by order in $p$. The kind of equations that we find seem totally new: defining the "Yukawa coupling" $Y_k(w) := \partial_{www} F_0^{X_k,ad}(w)$ we have

$$
Y_k(w) = \frac{1}{n_k} - \frac{1}{n_k^{n_k-1} F_{n_k}^{-2}} \left[ \frac{1}{n_k}, \ldots, \frac{n_k-1}{n_k}, \frac{1}{n_k-1}, \ldots, \frac{n_k-2}{n_k-1}, \frac{(-1)^k n_k e^{-w}}{(n_k-1)^{n_k-1}} \right]
$$

(78)

and we find for instance for the $t := t_{2,0}$-flow

$$
\partial_t v(x, t) = \{ v(x, t), H_{w,0} \} = Y_k(w) w_x,
$$

(79)

$$
\partial_t w(x, t) = \{ w(x, t), H_{w,0} \} = (v)_x + (2k-2)Y_k(w) w_x,
$$

(80)

which reduces to a wave equation with hypergeometric\footnote{In fact it was shown in [8] how to give for $k = 3$ a purely algebraic expression for the Yukawa [75]; the final result though sheds little more light on the nature of the equation [51].} non-linearity

$$
(w)_{tt} = (Y_k(w) w_x)_x + (2k-2) (Y_k(w) w_x)_t.
$$

(81)

3. The resolved conifold at higher genus and the Ablowitz–Ladik hierarchy

In this section we address the problem of deforming the hierarchies we constructed in Sec. 2 in order to incorporate higher genus corrections, and we will successfully find a way to do it in the case $k = 1$ with anti-diagonal action. After reviewing in Sec. 3.1 the general problem of constructing Hamiltonian integrable perturbations of dispersionless systems, we will exploit the connection of the Principal Hierarchy of $X_1^{ad}$ with a known integrable lattice to construct a candidate dispersive deformation whose $\tau$-function corresponds to higher genus Gromov–Witten potentials. A quasi-triviality property at $\mathcal{O}(\epsilon^2)$ will be established in Sec. 3.3 and a $\tau$-structure will be defined at this order and used to prove Theorem 1.3.
Finally in Sec. 3.4 we point out the difficulties and subtleties of the higher genus case, and provide a non-trivial \( g = 2 \) test of Conjecture 1.2.

3.1. **Dispersive perturbations of Hamiltonian systems.** In the terminology of Sec. 1.2 we have performed Step (1) of the construction of the hierarchies relevant to establish Conjecture 1.1 for the local theory of \( \mathbb{P}^1 \), at least for the case \( k = 1 \) and for the diagonal and anti-diagonal action. A full answer needs a prescription to perform Step (2), that is, to say, to find a way to unambiguously determine the coefficients \( A^{[g]}_{\alpha,p} \) in (3), or within the framework of Hamiltonian hierarchies, the dispersive corrections \( H^{[g]} \) of the \( g = 0 \) Hamiltonians

\[
H^{\text{disp}}_{\alpha,p}[u, \epsilon] = H^{[0]}_{\alpha,p}[u] + \epsilon H^{[1]}_{\alpha,p}[u] + \epsilon^2 H^{[2]}_{\alpha,p}[u] + \ldots,
\]

(82)

for local functionals \( H^{[n]}_{\alpha,p}[u] \)

\[
H^{[j]}_{\alpha,p}[u] = \int_{S^1} h^{[j]}_{\alpha,p}(u, u_x, u_{xx}, \ldots, u^{(j)}) dx,
\]

(83)

where \( h^{[j]}_{\alpha,p} \) is a differential polynomial, homogeneous of degree \( j \) with respect to the grading (34), and we have appended a superscript \( [0] \) to the dispersionless Hamiltonians of the Principal Hierarchy (25). The statement of integrability is then that

\[
\{ H^{\text{disp}}_{\alpha,p}[u, \epsilon], H^{\text{disp}}_{\beta,q}[u, \epsilon] \} = 0
\]

(84)

as a formal power series in \( \epsilon \).

As we emphasized in Sec. 1.2 in the context of the equivariant Gromov–Witten theory there are no general methods available to date to determine recursively \( H^{[n]}_{\alpha,p}[u] \) starting from the Hamiltonians of the Principal Hierarchy. However, suppose that a dispersive completion

\[
H^{\text{disp}}_{\alpha,p}[u, \epsilon] = \sum_{k=0}^{\infty} \epsilon^k H^{[k]}_{\alpha,p}[u]
\]

(85)

of one Hamiltonian \( \alpha = \alpha, p = \beta \) be known. We have the following

**Theorem 3.1** (17). Let \( H^{[0]}_{\alpha,p}[u], \alpha = 1, \ldots, n, p \in \mathbb{N} \) be Hamiltonian local functionals of a dispersionless hierarchy of integrable PDEs

\[
\{ H^{[0]}_{\alpha,p}[u], H^{[0]}_{\beta,q}[u] \} = 0
\]

(86)

and let \( H^{\text{disp}}_{\alpha,p}[u, \epsilon] \) be a dispersive deformation (83) of the Hamiltonian flow \( \alpha = \alpha, p = \beta \) for one pair \((\alpha, \beta)\) and given local functionals \( H^{[k]}_{\alpha,p}[u] \). Then if a dispersive completion of \( H^{\text{disp}}_{\alpha,p}[u, \epsilon] \) preserving involutivity of the flows \( \forall \epsilon \) exists

\[
\{ H^{\text{disp}}_{\alpha,p}[u, \epsilon], H^{\text{disp}}_{\beta,q}[u, \epsilon] \} = 0 \quad \forall \alpha, \beta, p, q,
\]

(87)

it is unique. In such a case, there exists a formal sum of linear differential operators

\[
D = \sum_{k=0}^{\infty} \epsilon^n D^{[k]},
\]

\[
D^{[0]} = \text{id}, \quad D^{[k]} = \sum b^{[k]}_{i_1, \ldots, i_n} (u_1, \ldots, u^{(k)}_1, \ldots, u_n, \ldots, u^{(k)}_n) \frac{\partial^{\sum_j i_j}}{\partial u_1^{i_1} \ldots \partial u_n^{i_n}},
\]

(88)

such that

\[
\int_{S^1} D^{[k]} h^{[0]}_{\alpha,p}(u) dx = \int_{S^1} h^{[k]}_{\alpha,p}(u, u_x, u_{xx}, \ldots, u^{(k)}) dx = H^{[k]}_{\alpha,p}[u]
\]

(89)

satisfies the involutivity condition (34). In (88), the coefficients \( b^{[k]}_{i_1, \ldots, i_n} \) are differential polynomials and \( \sum_{j=1}^{n} i_j \leq \left[ \frac{3k}{2} \right] \).
The theorem implies in our case that if a perturbation of one Hamiltonian of the Principal Hierarchy is integrable, then the involutivity condition singles out an operator, which order by order in $\epsilon$ reconstructs the dispersive tail of all flows. This operator is uniquely defined, modulo total derivatives and the relations defining the dispersionless Hamiltonian densities.

3.2. The resolved conifold and the Ablowitz–Ladik hierarchy. Consider now the Principal Hierarchy for the resolved conifold in the equivariantly Calabi–Yau case $\lambda_1 = -\lambda_2 = \lambda$. In this case the prepotential is

$$F_{X_1, ad}^{X_1} = -\frac{1}{2\lambda^2} v^2 w + \text{Li}_3(e^w)$$

and, from the fact that $\eta_{vv} = 0$, the non-linear wave equation has a vanishing rectangular term

$$w_{tt} = -\lambda^2 \left( \frac{e^w}{1 - e^w} w_x \right)_x.$$ 

This equation was recognized in [17] to be related to the dispersionless limit of the Ablowitz–Ladik lattice [1]. We will here review, almost verbatim, the arguments of [17] relating the solution of WDVV to such an integrable lattice. The basic flow of the system is

$$\dot{a}_n = -\frac{1}{2} (1 - a_n b_n)(a_{n-1} + a_{n+1}) + a_n,$$

$$\dot{b}_n = \frac{1}{2} (1 - a_n b_n)(b_{n-1} + b_{n+1}) - b_n,$$

where $\{a_n, b_n : Z \rightarrow C\}$. Introducing new variables

$$u_n = -\log(1 - a_n b_n),$$

$$y_n = \frac{1}{2i} \left( \log \frac{a_n}{a_{n-1}} - \log \frac{b_n}{b_{n-1}} \right),$$

the evolution can be written as a Hamiltonian flow generated by

$$H_{AL} = \sum_n \sqrt{(1 - e^{-u_n})(1 - e^{-u_{n-1}})} \cos y_n$$

with the Poisson bracket

$$\{u_n, y_m\} = \delta_{n,m-1} - \delta_{n,m}, \quad \{u_n, u_m\} = \{y_n, y_m\} = 0.$$ 

By taking the long-wave expansion we continuously interpolate the discrete dependent variables $u_n, t_n$ through functions $u(X, t), y(X, t)$

$$u_n = u(\epsilon n, \epsilon t), \quad y_n = y(\epsilon n, \epsilon t).$$

This leads, at the leading order in $\epsilon$, to the dispersionless system

$$u_t = \partial_X [(e^u - 1) \sin y],$$

$$y_t = \partial_X [e^{-u} \cos y].$$

In order to make contact with the Principal Hierarchy of the resolved conifold, we will follow the argument of [17] replacing $v(X), y(X)$ by

\[
\begin{align*}
x &:= i\lambda X, \\
v(x) &= iy(x)\lambda, \\
w(x) &= \frac{ie^{i\lambda \partial_x} - 1}{e^{i\lambda \partial_x} - 1} u(x).
\end{align*}
\]
In this way, the Poisson brackets of $w$ and $v$ take the standard form \(^{(23)}\), and the Hamiltonian \(^{(94)}\) becomes upon interpolation

\[
H_{AL} = \int h_{AL} \, dx \\
= \int \sqrt{\left(1 - \exp \left\{ \frac{1 - e^{i\lambda \partial_x}}{i\lambda \partial_x} w \right\} \right) \left(1 - \exp \left\{ \frac{e^{i\lambda \partial_x} - 1}{i\lambda \partial_x} w \right\} \right) \cosh \left(\frac{v}{\lambda}\right)} \, dx,
\]

(101)

\[
h_{AL} = (-1 + e^w) \cosh \left(\frac{v}{\lambda}\right) - \frac{(e^w \lambda^2 \cosh \left(\frac{u}{\lambda}\right) (4 (-1 + e^w) w_{xx} - 3(w_{xx})^2)) e^2}{24 (-1 + e^w)} + O \left(\epsilon^4\right).
\]

(102)

It turns out that the Ablowitz–Ladik lattice admits an infinite set of conserved currents \([1]\): as opposed to the Toda case, these currents do not come straightforwardly from a bi-Hamiltonian recursion associated to a local Poisson pencil, due to the non-existence of an Euler vector field for the prepotential \([90]\). It is easy to show that at the $O(\epsilon^1)$ an infinite number of them coincide with the densities of the Principal Hierarchy associated to the prepotential \([90]\): the condition for a dispersionless density $f(v(x), w(x))$ to be in involution with the dispersionless Ablowitz–Ladik Hamiltonian gives

\[
\left\{ H_{AL}^{(0)}, \int_{S_1} f \right\} = 0 \iff \partial_{ww}^2 f + \left(\frac{\lambda^2 e^w}{1 - e^w}\right) \partial_{vv}^2 f = 0.
\]

(103)

which is implied by \([19]\) for $\alpha = \beta$.

This connection provides us with a viable candidate hierarchy to relate to the Gromov–Witten theory of $X_1$ with $e_7(X_1) = 0$, and led us to our Conjecture \([12]\) connecting the dispersionful Ablowitz–Ladik system with the all-genus theory of $X_1$. To this aim, and as a first step towards the reconstruction of the dispersionful hierarchy, let us remark here that by Theorem 3.1, Eq. \((101)\) offers us a way to effectively construct the dispersive flows:

**Proposition 3.2.** The $D$-operator for the Ablowitz–Ladik hierarchy reads at $O(\epsilon^2)$

\[
D_{AL} f = f + e^2 \left[ \frac{e^{w(x)} (-1 + 2 e^{w(x)}) w'(x)^2 f_{vv} \lambda^4}{24 (-1 + e^{w(x)})^2} + \frac{e^{w(x)} w'(x)^2 f_{vvv} \lambda^4}{12 (-1 + e^{w(x)})} \\
+ \frac{e^{w(x)} w'(x) v'(x) f_{vvv} \lambda^2}{6 (-1 + e^{w(x)})} + \frac{v'(x)^2 f_{vvv} \lambda^2}{-12 + 24 e^{-w(x)}} + \frac{1}{12} v'(x)^2 f_{vvv} \lambda^2 \right] + O(\epsilon^4).
\]

(104)

Eq. \((104)\) was obtained, with minor discrepancies due to a different choice of variables, in \([17]\). A sketch of the proof can be found in Appendix A. Applying \((104)\) to the densities $h_{\alpha,\rho}$ of the Principal Hierarchy we find

\[
h_{v}^{(2)}(v, w, v_x, w_x) = \frac{1}{24 (-1 + e^{w(x)})^2} \left[ e^{w(x)} \lambda^2 \left(-w(x) + 2 e^{w(x)} (w(x) + 1) - 2\right) w'(x)^2 \\
- 2 (-1 + e^{w(x)}) \left( e^{w(x)} (w(x) - 1) + 1 \right) v'(x)^2 \right] z^2 + O \left( z^3 \right),
\]

(105)

\[
h_{w}^{(2)}(v, w, v_x, w_x) = \frac{e^{w(x)} ((-1 + 2 e^{w(x)}) \lambda^2 w'(x)^2 - 2 (-1 + e^{w(x)}) v'(x)^2) z}{24 (-1 + e^{w(x)})^2}.
\]

\(^4\)In fact all of them, with the sole exception \([17]\) of the one generating phase shifts of $a_n$, $b_n$.  

17
\[
+ \frac{e^{w(x)}}{24 (-1 + e^{w(x)})^2} \left[ 4 \left(-1 + e^{w(x)}\right) w'(x)v'(x)\lambda^2 \\
+ v(x) \left( (-1 + 2e^{w(x)}) \lambda^2 w'(x)^2 - 2 \left(-1 + e^{w(x)}\right) v'(x)^2 \right) \right] z^2 + O(z^3) .
\]

As an example, the leading order correction to (67) reads
\[
w_{tt} = \left( -\frac{\lambda^2 e^w}{1 - e^w w_x} \right)_x - \frac{e^{w(x)}}{24 (-1 + e^{w(x)})^2} \left[ \left(1 + 4e^{w(x)} + e^{2w(x)}\right) \lambda^2 w'(x)^3 \\
+ (-2 + 2e^{2w(x)}) \left(v'(x)^2 - 2\lambda^2 w''(x)\right) w'(x) - 2 \left(-1 + e^{w(x)}\right)^2 \\
\times \left(2v'(x)v''(x) - \lambda^2 w^{(3)}(x)\right) \right] e^\epsilon + O(\epsilon^4) .
\]

3.3. Quasi-triviality and genus one Gromov–Witten invariants. A key ingredient in the Dubrovin–Zhang analysis of bi-Hamiltonian evolutionary hierarchies, which proved instrumental in their proof [20] of the F²/Toda correspondence, is the fact the hierarchy verifying Conjecture 1.1 satisfies a quasi-triviality property:

**Definition 3.1.** A transformation of the form
\[
u^\alpha \rightarrow z^\alpha = u^\alpha + \sum_{k=1}^\infty e^{2k} F^\alpha_k(u, u_x, \ldots, u^{(m(k))}) ,
\]
with \(m(k)\) a monotonically increasing, positive integer-valued sequence and \(F^\alpha_k\) a degree \(k\) rational function of \(u^{(j)}\) for \(j > 0\), will be called a quasi-Miura transformation. The hierarchy \(\{\mathcal{H}\}\) is called quasi-trivial if there exists a quasi-Miura transformation reducing it, in the new variables, to its dispersionless \(\epsilon = 0\) truncation.

The quasi-Miura transformation (108) is said to be \(\tau\)-symmetric if there exists a formal power series
\[
\mathcal{F}(\epsilon, u, u_x, \ldots) = \sum_{k=0}^\infty e^{2k} \mathcal{F}^k(u, u_x, \ldots, u^{(m(k)-2)})
\]
where again \(\mathcal{F}^k(u, u_x, \ldots, u^{(m(k)-2)})\) is a degree \(k\) rational function of \(u^{(j)}\) for \(j > 0\), such that
\[
F_{k,\alpha}(u, u_x, \ldots, u^{(m(k))}) = \frac{\partial^2 \mathcal{F}_k}{\partial x^\alpha \partial x^0}(u, u_x, \ldots, u^{(m(k)-2)}).
\]

Comparing (108) with (43) identifies \(\mathcal{F}_k\) as the \(O(\epsilon^k)\) dispersive correction to the logarithm of the dispersionless \(\tau\) function, i.e., in the case of the Principal Hierarchy [25], of the genus zero topological \(\tau\)-function of Theorem 2.3. Conjecture 1.1 then states that precisely one such object should correspond to the full descendent, all-genus Gromov–Witten potential.

The rest of this section is devoted to the use of a quasi-triviality transformation to give a proof of Conjecture 1.2 at \(O(\epsilon^2)\), that is, for \(g = 1\) Gromov–Witten invariants. Our proof consists of the following three steps:

a) proving that the Ablowitz–Ladik hierarchy is quasi-trivial at \(O(\epsilon^2)\);

b) fixing a suitable choice of dependent variables leading to a \(\tau\)-symmetric transformation (110) at \(O(\epsilon^2)\);

c) proving that the logarithm of the \(\tau\)-function thus obtained coincides with the genus one, full descendent potential of \(X_1\) with anti-diagonal action.
In the context of the usual theory of (conformal) semi-simple Frobenius structures, step (a) is a consequence of the theory of \((0,n)\) Poisson pencils on the loop space, while step (b) and (c) follow from the axiom of linearization of Virasoro constraints. In absence of bi-Hamiltonianity and possibly Virasoro-type constraints, we will need to perform steps (a)-(c) “by hand”, guided to some extent by the analogy with the Extended Toda hierarchy.

Let us start from step (a):

**Theorem 3.3.** There exists an infinitesimal time-\(\epsilon\) canonical quasi-Miura transformation

\[
 u^\alpha \to z^\alpha = u^\alpha + \epsilon \{u^\alpha, K\} + \mathcal{O}(\epsilon^2),
\]

where

\[
 K = -\frac{\epsilon}{24} \int_{S^1} \left[ F_+(x) \log F_+(x) + F_-(x) \log F_-(x) - 2 \log \left( -1 + e^{w(x)} \right) v'(x) \right] dx
\]

and

\[
 F_\pm(x) := v'(x) \pm \sqrt{\frac{e^{w(x)}}{-1 + e^{w(x)}}} \lambda w'(x)
\]

which sends solutions of the Principal Hierarchy to those of its \(\mathcal{O}(\epsilon^2)\) correction \[106\].

To prove it we will make use of the following technical lemma from \[17\]:

**Lemma 3.4.** A density \(h(u, u_x, \ldots)\), depending at most rationally on the jet variables \(u^{(n)}\) for \(n > 1\) is a total derivative \(\partial_x g(u, u_x, \ldots)\) if and only if

\[
 \frac{\delta}{\delta u(y)} \int_{S^1} h(u(x), u_x(x), \ldots) dx = 0.
\]

**Proof of Theorem 3.3.** The proof follows from a very lengthy, but straightforward application of Lemma 3.4. The Hamiltonian densities \(h_{\alpha,p}^{\text{disp}}(z, z_x, z_{xx}, \ldots)\) obtained by composition of the dispersionless densities \(h_{\alpha,p}(u)\) with the \(\mathcal{O}(\epsilon^2)\) quasi-Miura transformation \[111\] are given by

\[
 h_{\alpha,p}^{\text{disp}}(\epsilon, z, z_x, z_{xx}, \ldots) := h_{\alpha,p}(u(\epsilon, z, z_x, \ldots)) = h_{\alpha,p}(z) + \epsilon \{h_{\alpha,p}, K\} + o(\epsilon^2)
\]

since the trasformation generated by \(K\) is canonical. In particular the \(\mathcal{O}(\epsilon^2)\) correction is

\[
 h_{\alpha,p}^{[2],\text{disp}}(z, z_x, z_{xx}) = \epsilon \{h_{\alpha,p}, K\}.
\]

We claim that this reproduces the leading dispersive correction \[106\] of the dispersionless Ablowitz–Ladik flows. In the following we denote by \(h_{\alpha,p}^D\) the densities \[106\] we got by acting with the \(D\)-operator \[104\], to distinguish them from the ones obtained via \[111\]; accordingly, the corresponding generating functions will be written \(h_{\alpha,D}^q(z)\) and \(h_{\alpha,D}^{[2]}(z)\).

Define

\[
 r_\alpha(z) := h_{\alpha,D}^q(z) - h_{\alpha,D}^D(z).
\]

We refrain here from reproducing the exact form of \(r_\alpha(z)\), which would occupy alone a few pages. A direct computation using \[104\] and \[112\] shows that

\[
 \frac{\delta}{\delta u(x)} \int_{S^1} r_{\alpha}^{[2]}(z)(u, u_y, u_{yy}) dy = 0.
\]

Therefore we conclude that

\[
 H_{\alpha,p}^{q,[2]} = H_{\alpha,p}^{D,[2]}. \tag{119}
\]

\[5\]We will be happy to provide the interested reader with the details of this calculation.
Remark 3.5. Even though the Hamiltonian flows they generate are equal by (119), the Hamiltonian densities $h_{\alpha,p}^{\text{qu}}$ and $h_{\alpha,p}^{\text{Dop}}$ differ greatly in form; in particular the quasi-Miura transformation (111) introduces a rational, rather than polynomial, dependence of $h_{\alpha,p}^{\text{qu}}$ on the jet variables $u^{(n)}$ for $n \geq 1$, which should disappear only at the level of the flows by (118). For the basic dispersionless Hamiltonian of the Ablowitz–Ladik lattice we have for example

$$\{ (1 - e^w) \cosh \left( \frac{v}{\lambda} \right), K \} = -\frac{P(u, u_x, u_{xx}, u^{(3)})}{48 (1 - e^{w(x)})^2 (e^{w(x)})^2 w'(x)^2 - (1 - e^{w(x)}) v'(x)^2}$$

(120)

where $P(u, u_x, u_{xx}, u^{(3)})$ looks like

$$P = e^{w(x) - \frac{w(x)}{\lambda}} \lambda^2 \left[ (1 + e^{\frac{2w(x)}{\lambda}}) \left( -3 e^{3w(x)} \lambda^4 w'(x)^6 + e^{w(x)} \left( -1 + e^{w(x)} \right) \lambda^2 \right) \right. \\
\times \left. \left( e^{w(x)} \left( 1 + 2 e^{w(x)} \right) w''(x) \lambda^2 + \left( 1 + 5 e^{w(x)} \right) v'(x)^2 \right) \right]\left( 1 + 5 e^{w(x)} \right) - 2 e^{w(x)} \left( -1 + e^{w(x)} \right)^2 \\
\times \left. \lambda^2 \left( e^{w(x)} \lambda^2 w^{(3)}(x) - 2 v'(x) w''(x) \right) \right) w'(x)^3 - 2 e^{w(x)} \left( -1 + e^{w(x)} \right)^2 v'(x)^4 + \ldots \right].$$

(121)

It is particularly instructive to consider the result of the quasi-Miura transformation on the variable $w$. We find

$$\epsilon \{ w, K \} = -\lambda^2 e^2 \frac{\partial^2 \tilde{F}_1(w, v_x, w_x)}{\partial x^2},$$

(122)

where

$$\tilde{F}_1(w, v_x, w_x) := \frac{1}{24} \log \left( v'(x)^2 + \frac{\lambda^2 e^w}{1 - e^w} w'(x)^2 \right) + \frac{1}{12} \text{Li}_1(e^w).$$

(123)

On the other hand, for the $v$ variable we find

$$\epsilon \{ v, K \} = -\lambda^2 e^2 \left( \frac{\partial^2 \tilde{F}_1(w, v_x, w_x)}{\partial x \partial t^{2,0}} + \frac{1}{6} \frac{\partial^2 \text{Li}_1(e^w)}{\partial x \partial t^{2,0}} \right) \neq -\lambda^2 e^2 \frac{\partial^2 \tilde{F}_1(w, v_x, w_x)}{\partial x \partial t^{2,0}},$$

(124)

that is, the quasi-triviality transformation (111) is not $\tau$-symmetric. Indeed, except for the KdV case, the incompatibility between canonicity and $\tau$-symmetry of the quasi-Miura transformation seems to be a fairly generic fact also for bi-Hamiltonian systems like the Extended Toda hierarchy. Quite interestingly, the similarity with the case of the Gromov–Witten theory of $\mathbb{P}^1$ and the Extended Toda hierarchy is even more striking, as the discrepancy between the transformation generated by $K$ and the one via the logarithm of a dispersive $\tau$-function is present in only half of the change of variables, and it is equal to twice the term independent of space derivatives (in the language of [18], the $G$-function) inside $\tilde{F}_1$.

It should be emphasized that the form of the $G$-function in the Toda case relies on the existence of a grading condition for the Frobenius manifold associated to $\mathcal{QH}^*(\mathbb{P}^1)$, which in particular allows to fix the degree zero terms at $g = 1$ [18]. As we will see, in our case this is achieved by shifting the form of the $g = 1$ full-descendent free energy by the constant map term

$$\langle \tau_0(1) \rangle_{X, 1, 1, 0}^X = -\int_{\mathcal{M}_{1,1}} \lambda_1 = -\frac{1}{24},$$

(125)

\footnote{This point was strongly emphasized to us in an enlightening discussion with B. Dubrovin.}
where \( \lambda_1 = c_1(E) \) is the Chern class of the Hodge line bundle on \( \mathcal{M}_{1,1} \), through

\[
\tilde{F}_1 \to F_1 := \tilde{F}_1 - \frac{w(x)}{24}.
\]  

(126)

Inspired by the analogy with the \( \mathbb{P}^1 / \text{Toda} \) case, we are then led to consider the following \( \tau \)-symmetric ansatz for the choice of dependent variables at \( O(\epsilon^2) \):

\[
u_\alpha \to \nu_\alpha + \epsilon^2 \frac{\partial^2 F_1(w, v_x, w_x)}{\partial x^2 \partial t^{\alpha,0}} + O(\epsilon^4),
\]

(127)

where

\[
F_1 = \frac{1}{24} \log \left( \nu'(x)^2 + \frac{\lambda^2 e^{w(x)}}{1 - e^{w(x)}} \nu'(x)^2 \right) + \frac{1}{12} \text{Li}_1(e^{w(x)}) - \frac{w(x)}{24}. \tag{128}
\]

We are now in position to prove Theorem 1.3: by the definition of quasi-triviality, the \( O(\epsilon^2) \) correction to the logarithm of the \( \tau \)-function \( F_0 \) in (29) should be obtained by plugging into (128) the solution of the Principal Hierarchy with initial data (26); the result of the composition will be again denoted by the same symbol \( F_1(t) \). Accordingly, we introduce genus 1 “big correlators”

\[
\langle \langle \tau_{p_1} \phi_{\alpha_1}, \ldots, \tau_{p_k} \phi_{\alpha_k} \rangle \rangle_{1} := \frac{\partial^k F_1(t)}{\partial \alpha_1^{p_1} \ldots \partial \alpha_k^{p_k}}. \tag{129}
\]

Proof of Theorem 1.3. The statement for \( g = 0 \) was proven in Sec. 2.2 (Theorem 2.3 and Proposition 2.5). For \( g = 1 \), notice that the descendent Gromov–Witten invariants of \( X_1 \) are completely determined in a recursive fashion by the following two formulas: the first is the \( g = 1 \) case of the higher genus multi-covering formula found in [10, 24, 30, 35, 39] that yields the primary potential of \( X_1 \) as

\[
F_{X_1}^{X_1}(t^2, 0) = -\frac{t^2}{24} + \sum_{d=1}^{\infty} N_{1,d} e^{dt^2} = -\frac{t^2}{24} + \frac{1}{12} \text{Li}_1(e^{t^2}). \tag{130}
\]

The second is the set of \( g = 1 \) topological recursion relations [14, 27, 37]

\[
\langle \tau_p(\phi_\alpha) \rangle_{1,1,d}^{X_1} = \sum_{d_1 + d_2 = d} \langle \tau_{p-1}(\phi_\alpha) \tau_0(\phi_\nu) \rangle_{0,2,d_1}^{X_1} \eta_{\mu \nu} \langle \tau_0(\phi_\mu) \rangle_{1,1,d_2}^{X_1} + \frac{1}{24} \eta_{\mu \nu} \langle \tau_{p-1}(\phi_\alpha) \tau_0(\phi_\nu) \tau_0(\phi_\mu) \rangle_{0,3,d}^{X_1}, \tag{131}
\]

that fully determine genus one descendent invariants in terms of the genus one primaries and genus zero descendents. We will prove here that the Ablowitz–Ladik \( \tau \)-function (128) implies both (130) and (131).

Consider first the small phase reduction of \( \mathcal{F}(t) \), i.e.

\[
u^\alpha(t) \bigg|_{t^{\alpha,p} = 0}^{t^{\alpha,p} = 0} = t^{\alpha,0} + \delta^{\alpha,0} x.
\]  

(132)

Replacing into (128) we find

\[
\mathcal{F}_1(t) \bigg|_{t^{\alpha,p} = 0}^{t^{\alpha,p} = 0} = -\frac{t^2}{24} + \frac{1}{12} \text{Li}_1(e^{t^2}), \tag{133}
\]

which proves (130).
To see that $F_1(t)$ correctly embeds the full-descendent information too, we follow [18] and compute

$$C_{\alpha,p} := \frac{\partial F_1}{\partial u^\alpha} - \frac{\partial^2 F_0}{\partial t \partial u^\alpha} \partial u^\alpha \frac{\partial F_1}{\partial u^\alpha},$$

$$= \sum_{\gamma=1,2} \left[ \frac{\partial F_1}{\partial u^\gamma} \frac{\partial F_0}{\partial \phi} + \frac{\partial^2 F_1}{\partial \phi \partial u^\gamma} \frac{\partial u^\gamma}{\partial \phi} - \partial \eta^{[0]}_{\partial p-1} \eta^{\mu \nu} \left( \frac{\partial F_1}{\partial u^\gamma} \frac{\partial u^\gamma}{\partial \phi} + \frac{\partial F_1}{\partial \phi} \frac{\partial \eta^{\mu \nu}}{\partial \phi} \right) \right]$$

$$= \sum_{\gamma=1,2} \left[ \frac{\partial F_1}{\partial u^\gamma} \frac{\partial u^\gamma}{\partial \phi} \eta^{[0]}_{\partial p-1} + \frac{\partial F_1}{\partial \phi} \frac{\partial \eta^{\mu \nu}}{\partial \phi} \right]$$

$$- \partial \eta^{[0]}_{\partial p-1} \eta^{\mu \nu} \left( \frac{\partial F_1}{\partial u^\gamma} \frac{\partial u^\gamma}{\partial \phi} + \frac{\partial F_1}{\partial \phi} \frac{\partial \eta^{\mu \nu}}{\partial \phi} \right)$$

$$= \sum_{\gamma=1,2} \frac{\partial F_1}{\partial u^\gamma} \frac{\partial \eta^{[0]}_{\partial p-1}}{\partial \phi},$$

(134)

where in the second line we used the chain rule and the fact that

$$\partial \eta^{[0]}_{\partial p-1} = \langle \phi_{p-1} \rangle_0 \frac{\partial^2 F_0}{\partial \eta^{\mu \nu} \partial \phi},$$

(135)

while in the third line we used the genus zero topological recursion relations [50]

$$\frac{\partial u^\alpha}{\partial \beta} = \eta^{\gamma \beta} \frac{\partial^2 F_0}{\partial \gamma \partial \eta^{\alpha \beta}} = \eta^{\alpha \beta} \frac{\partial^2 F_0}{\partial \eta^{\alpha \beta} \partial \gamma} \eta^{\gamma \beta} \frac{\partial^2 F_0}{\partial \gamma \partial \eta^{\alpha \beta}}$$

$$= \frac{\partial u^\alpha}{\partial \beta} \eta^{\gamma \beta} \eta^{\gamma \beta},$$

(136)

Moreover Eq. [66] with $\lambda_1 = -\lambda_2 = \lambda$ and the explicit form [128] yield

$$\sum_{\gamma=1,2} \frac{\partial F_1}{\partial u^\gamma} \frac{\partial u^\gamma}{\partial \phi} \eta^{\mu \nu} = \frac{\partial F_1}{\partial v} \frac{\partial v}{\partial \phi} + \frac{\partial F_1}{\partial w} \frac{\partial w}{\partial \phi} = \eta^{\mu \nu} 2v' \frac{\partial v}{\partial \phi} + 2 \frac{\lambda^2 w'(x) \partial w(x) \partial \phi}{1-e^{w(x)}}$$

$$= -\frac{\lambda^2}{12} \delta^{\mu \nu}.$$

(137)

This implies

$$C_{\alpha,p} = \frac{\lambda^2}{12} \frac{\partial \eta^{[0]}_{\partial p-1}}{\partial \phi} = \frac{\lambda^2}{12} \frac{\partial^2 F_0}{\partial \eta^{\mu \nu} \partial \phi},$$

(138)

Combining the last equality with the definition of $C_{\alpha,p}$ in the first line of [134], we obtain

$$\langle \phi_{p-1} \rangle_0 \eta^{\mu \nu} \langle \phi_{p-1} \rangle_0 = \frac{\lambda^2}{24} \frac{\partial^2 F_0}{\partial \eta^{\mu \nu} \partial \phi} \frac{\partial \eta^{\mu \nu}}{\partial \phi},$$

(139)

which, setting $t^{\alpha,p} = 0$ for $p > 0$ in [129] and expanding in $e^{t^{z,0}}$, implies [131].

$$\square$$

3.4. A look at the higher genus theory. A natural further step would be to generalize the results of the previous section to higher genus Gromov–Witten invariants. As usual, however, the degree of difficulty undergoes a phase transition as soon as $g > 1$, and the search of straightforward generalizations of the methods we used becomes unwieldy. In particular, the construction of the quasi-triviality transformation appears to be very hard, yet alone finding a suitable $\tau$-symmetric form to compare with the higher genus Gromov–Witten potentials.

However, there is still room for a number of non-trivial tests of Conjecture [12]. To see this, recall that in the previous section we found three ways to construct the $O(\epsilon^2)$ dispersive tail of the Ablowitz–Ladik hierarchy:
invariants are perturbative expansion in $\epsilon$.

On the other hand, focusing on the first line we see that at the leading order in $\tau$ the relevant Assumption 3.1.

Gromov–Witten invariants.

zero up to a quasi-Miura transformation whose restriction to primaries is determined by (126). In the following we will make the following important up to terms related to constant maps contribution upon restriction to primary fields, as in (122) and (124) this is not the case for (ii) and (iii), where $\tau$-symmetry is broken in the canonical setup; moreover, the canonical free energy $\tilde{F}$ such that $w^{[d,\text{op}]}(t) = \partial_x^2 \tilde{F}(t)$ coincides with the topological free energy $F$ up to a Miura transformation, consisting in a shift by terms whose restriction to primary invariants involves only degree zero terms. The situation is schematized in Table 1.

| D-operator | Canonical q.t. | $\tau$-symmetric q.t. |
|------------|----------------|------------------------|
| $w^{[d,\text{op}]}(t, \epsilon)$ | $w^{[\text{c.q.t.}]}(t, \epsilon)$ | $w^{[\tau-\text{s.q.t.}]}(t, \epsilon)|_{d>0}$ |
| $v^{[d,\text{op}]}(t, \epsilon)$ | $v^{[\text{c.q.t.}]}(t, \epsilon)$ | $\neq v^{[\tau-\text{s.q.t.}]}(t, \epsilon)|_{d>0}$ |

**Table 1.** Relations between solutions of the dispersionful Ablowitz–Ladik hierarchy at $O(\epsilon^2)$. The equality between the second and the third column holds up to a Miura transformation whose restriction to the small phase space involves only degree zero terms.

The objects to construct for the purpose of computing higher genus Gromov–Witten invariants are $v^{[\tau-\text{s.q.t.}]}(t, \epsilon)$ and $w^{[\tau-\text{s.q.t.}]}(t, \epsilon)$ at higher order in $O(\epsilon)$: as we emphasized, the relevant $\tau$-symmetric quasi-Miura transformation seems however very difficult to obtain. On the other hand, focusing on the first line we see that at the leading order in the perturbative expansion in $\epsilon$ we have

$$w^{[d,\text{op}]}(t, \epsilon) = w^{[\tau-\text{s.q.t.}]}(t, \epsilon) = \partial_x^2 F(t) + O(\epsilon^4)$$  \hspace{1cm} (140)

up to terms related to constant maps contribution upon restriction to primary fields, as in (126). In the following we will make the following important

**Assumption 3.1.** The equality (140) holds true at genus $O(\epsilon^4)$:

$$w^{[d,\text{op}]}(t, \epsilon) = w^{[\tau-\text{s.q.t.}]}(t, \epsilon) = \partial_x^2 F(t) + O(\epsilon^6)$$  \hspace{1cm} (141)

up to a quasi-Miura transformation whose restriction to primaries is determined by degree zero Gromov–Witten invariants.

That is, even if we do not know the form of $w^{[d,\text{op}]}(t, \epsilon)$ as a rational function in the derivatives of the fields beyond $O(\epsilon^2)$, we assume that it is a double derivative of some (rational) local functional $F$. In our situation, we have little guidance for the construction of the right quasi-Miura transformation which determines the form of $F$ at higher genus, but on the other hand computing higher order corrections to the $D$-operator (104), and therefore to $w^{[d,\text{op}]}(t)$, is just a matter of computational time and stamina. Indeed the involutivity condition (31) gives a self-contained way to find $w^{[d,\text{op}]}(t, \epsilon)$ at any order in $\epsilon$, thus allowing a complete recursive reconstruction of the $\epsilon$ expansion of the flows. As for the genus one case, we might be missing a possible contribution from constant maps here; the computation below will indeed be insensitive to degree zero invariants.

**Proof of Theorem 1.4:** we will work out the consequences of Theorem 3.1 at $O(\epsilon^4)$ by putting $H_{\alpha,p} = H_{AL}$, where the $O(\epsilon^4)$ expansion of $H_{AL}$ was given in (102). This determines
the two-loops $D$-operator of the Ablowitz–Ladik lattice; for future use we give here the expression of the coefficients $b_{vv}^{[4]}$ and $b_{vvv}^{[4]}$

$$D^{[4]}f = b_{vv}^{[4]} f_{vv} + b_{vvv}^{[4]} f_{vvv} + \ldots$$

where, up to a total derivative, we have

$$b_{vv}^{[4]} = \frac{\lambda^2}{5760 (1 + e^{w(x)})^4} \left[ -8 e^{w(x)} (1 + e^{2w(x)}) v'(x) + 4 (1 + e^{w(x)}) \right]$$

$$\times \left( 11 + 7 e^{w(x)} \right) \lambda^2 w''(x) v'(x)^2 - 8 (1 + e^{w(x)}) \left( e^{w(x)} (1 + 19 e^{w(x)}) + 2 \right) \lambda^2$$

$$\times w'(x) v''(x) v'(x) + \lambda^2 \left( 4 - e^{w(x)} (15 e^{w(x)} - 4 + e^{w(x)}) + 19 \right) \lambda^2 w''(x) v'(x)^2$$

$$+ 8 e^{w(x)} (1 + e^{w(x)}) \left( e^{w(x)} (7 + 3 e^{w(x)}) + 1 \right) \lambda^2 w'(x)^2 + (1 + e^{w(x)})$$

$$\times \left( 5 + 7 e^{w(x)} \right) v''(x)^2 \right]$$

$$b_{vvv}^{[4]} = \frac{1}{17280} \left[ \frac{\lambda^4}{(1 - e^{w(x)})^3} \right]$$

$$\times \left( \frac{1}{1 + e^{w(x)}} - e^{w(x)} \left( e^{w(x)} (107 + 32 e^{w(x)}) + 131 \right) - 46 \right) w'(x) v'(x) w''(x) \lambda^2$$

$$+ \frac{3 \left( e^{w(x)} (119 + 183 e^{w(x)}) + 46 \right)}{(1 + e^{w(x)})^3} - 12 \log \left( \frac{1 + e^{w(x)}}{1 - e^{w(x)}} \right) - 4 w(x) \right)\right)$$

$$v'(x)^2 v''(x) \lambda^2$$

$$- \frac{144 e^{w(x)} (1 + e^{w(x)}) v''(x) v''(x)}{(1 + e^{w(x)})^3} - 12 \left( -3 \left( -5 + 9 e^{w(x)} \right) \right) - 2 \log \left( \frac{1 + e^{w(x)}}{1 - e^{w(x)}} \right)$$

$$+ \frac{6 w(x)}{v'(x)^2 v''(x)} \right]$$

As an application of (104) and (144), consider the $t^{2.1}$ flow generated by $H_{2.1}$. For reasons that will be clear in a moment, we would like to compute the solutions $v^{[d-op]}(t^{1.0}, t^{2.0}, t^{2.1}, \epsilon)$ and $w^{[d-op]}(t^{1.0}, t^{2.0}, t^{2.1}, \epsilon)$, with all other times set to zero, of the $t^{2.1}$ flow. This will lead us to a proof of Theorem 1.3.

From (39), (42) and (43)-(51) we have that

$$h_{2,1}^{[0]}(v, w) = -\frac{v^3}{6 \lambda^2} + v \text{Li}_2(e^w)$$

and therefore

$$h_{2,1}^{d-op} := D_{AL} h_{2,1}^{[0]} = h_{2,1}^{[0]} + \epsilon^2 h_{2,1}^{[2]} + \epsilon^4 h_{2,1}^{[4]} + \mathcal{O}(\epsilon^6),$$

where

$$h_{2,1}^{[2]} = \frac{e^{w(x)}}{24 (1 + e^{w(x)})^2} \left[ 4 \left( 1 + e^{w(x)} \right) w'(x) v'(x) \lambda^2 + v(x) \left( -1 + 2 e^{w(x)} \right) \lambda^2 w'(x)^2$$

$$- 2 \left( -1 + e^{w(x)} \right) v'(x)^2 \right],$$

$$h_{2,1}^{[4]} = \frac{1}{\lambda^2} (v b_{vv}^{[4]} + b_{vvv}^{[4]}),$$

while on the other hand

$$h_{1,0}^{d-op} = h_{1,0}^{[0]} = -\frac{vw}{\lambda^2}. $$
Let us solve the dispersive equations
\[
\frac{\partial u^\alpha}{\partial t^{2,1}} = \left\{ u^\alpha, \int_S t_2^{1,-\op}(v, w) \right\}
\]
perturbatively in \(t^{2,1}\) with the topological Cauchy datum \(\mathbf{132}\). We find
\[
w^{[d-\op]}(x, t^{2,0}, t^{2,1}) = t^{2,0} + t^{2,1} x + (t^{2,1})^2 \lambda^2 \log \left(1 - e^{t^{2,0}}\right) + \frac{e^{2t^{2,0}} (t^{2,1})^3 x^2}{1 + e^{t^{2,0}}} + \ldots
\]
\[
+ \left( \frac{e^{2t^{2,0}} (t^{2,1})^2 \lambda^2}{12 (-1 + e^{t^{2,0}})^2} + \frac{e^{2t^{2,0}} (1 + e^{t^{2,0}}) (t^{2,1})^3 x^2}{12 (-1 + e^{t^{2,0}})^3} + \ldots \right) e^2
\]
\[
+ \left( \frac{e^{2t^{2,0}} (1 + 4e^{t^{2,0}}) (t^{2,1})^2 \lambda^2}{240 (-1 + e^{t^{2,0}})^4} + \ldots \right) e^4 + O(e^6). \tag{151}
\]
From now on we put \(t^{2,0} =: t\). The last line of \(\mathbf{151}\) and the assumption \(\mathbf{141}\) combined together lead to
\[
\left. \frac{\partial^4 F_2}{\partial x^p \partial(t^{2,1})^2} \right|_{x^p, t^{2,1} > 0} = \frac{e^t (1 + 4e^t + e^{2t})}{120 (-1 + e^t)^4} = \frac{1}{120} \text{Li}_{-3} (e^t). \tag{152}\]
In Gromov–Witten theory the left hand side would represent the small phase correlator \(\langle\langle \phi_1, \phi_1, \tau_1 \phi_2, \tau_1 \phi_2 \rangle\rangle_{X_1, g, \text{sp}}\), where we define
\[
\langle\langle \tau_{p_1} \phi_{\alpha_1} \ldots \tau_{p_k} \phi_{\alpha_k} \rangle\rangle_{X_1, g, n+k,d} (x, t) := \sum_{d, n \geq 0} \frac{1}{n!} \left( \tau_{p_1} \phi_{\alpha_1} \ldots \tau_{p_k} \phi_{\alpha_k} \right) x^{d, \phi_1 + t \phi_2 + \ldots + t \phi_1 + t \phi_2} \right\rangle_{X_1, n+k,d}.
\]
Applying twice the puncture equation to \(\langle\langle \phi_1, \phi_1, \tau_1 \phi_2, \tau_1 \phi_2 \rangle\rangle_{X_1, g, \text{sp}}\) we can kill the two descendent insertions and reduce to the double derivative of the primary potential
\[
2 \sum_{d \geq 0} \sum_{n=0}^\infty \frac{(t)^n}{n!} \left( \phi_2, \phi_2, \phi_2, \ldots, \phi_2 \right)_{2,n+2,d} = 2 \frac{\partial^2 F_2(t)}{\partial t^2}, \tag{154}\]
that is
\[
\frac{\partial^2 F_2(t)}{\partial t^2} = \frac{1}{240} \text{Li}_{-3} (e^t). \tag{155}\]
This reproduces exactly the higher genus formula for primary Gromov–Witten invariants of \(X_1\) \([10][24][30][33][35]\)
\[
F_{g}^{X_1}(t) = \sum_{d=0}^\infty N_{g,d}^{(1)} e^{dt} = \frac{|B_{2g}|}{2g(2g-2)!} \text{Li}_{2g-2}(e^t) + \frac{|B_{2g}B_{2g-2}|}{2g(2g-2)(2g-2)!} \tag{156}\]

3.5. Higher descendent flows and the Ablowitz–Ladik equations. By the same token, the complete solution \(w(t) = \partial^2 F(t)\) of all flows should contain information on descendent invariants; however, the discrepancy between \(\tilde{F}(t)\) and \(F(t)\), which amounts to constant map terms when restricted to primaries, might also affect positive degree invariants when it comes to computing descendents. In particular the terms of \(O(t^{2,1})^{n+2}\) of \(\mathbf{151}\) complete the right genus 2 Gromov–Witten invariants with single descendent insertions at \(n\) points only if \(n \leq 2\). As for the genus one case, the precise choice of dependent variables for the Ablowitz–Ladik equations is then crucial for the computation of Gromov–Witten invariants, and in particular it should correct the hydrodynamic Poisson structure \([22]\).
which is left invariant by construction in the $D$-operator formalism, by higher order terms in $\epsilon$.

It is nonetheless remarkable that the dispersive Ablowitz–Ladik flows in the $D$-operator form satisfy a number of constraints induced from the topology of moduli spaces of stable maps. As an example, a little experimentation at the next few orders in $t^{2,1}$ shows that

$$
\frac{1}{n!} \frac{\partial w^{[d-\text{op}]}(x, t, t^{2,0}, t^{2,1})}{\partial (t^{2,1})^n} \big|_{t^{2,1} = 0} = \sum_{k=0}^{n} a_{k,n}(t) x^k
$$

(157)

with

$$
a_{k,n}(t) = \binom{n}{k} \frac{\partial^k a_{0,n-k}(t)}{\partial t^k}
$$

(158)

It is noteworthy that the relation (158), which in Gromov–Witten theory would be a consequence of the string axiom, is realized by the dispersive Ablowitz–Ladik flows; we checked this up to $O((t^{2,1})^7)$ (i.e. $n \leq 5$). Along the same lines, it is straightforward to switch on the $t^{1,1}$-flow of the Ablowitz–Ladik hierarchy and see that the dilaton constraint is satisfied too. As an example, for the $O((t^{2,1})^2)$, $O(\epsilon^{2g})$ coefficient $\tilde{w}_g^{(2)}(t^{1,1}, t)$ of $w(x, t, t^{1,1}, t^{2,1})$ we can give a closed expression for its $t^{1,1}$ dependence

$$
\tilde{w}_g^{(2)} := \sum_{n \geq 0} \frac{(t^{1,1})^n}{n!} \left( \langle \phi_1, \phi_1, \tau_1 \phi_2, \tau_1 \phi_2, \tau_1 \phi_1, \ldots, \tau_1 \phi_1 \rangle \right)_{g,\text{sp}}^{\text{n times}}
$$

$$
= \left( \frac{1}{1 - t^{1,1}} \right)^{2g+2} \frac{\partial^2}{\partial y^2} F_g(y) \bigg|_{y = \frac{t^{1,1}}{1 - x^{1,1}}}, \quad g = 0, 1, 2
$$

(159)

and it is immediate to see that the small-phase space dilaton equation holds

$$
\left( (1 - t^{1,1}) \frac{\partial}{\partial t^{1,1}} - t \frac{\partial}{\partial t} - 2 - 2g \right) \tilde{w}_g^{(2)} = 0.
$$

(160)
APPENDIX A. DISPERSIVE EXPANSION OF THE ABOLOWITZ–LADIK HIERARCHY

We collect here the details of the reconstruction of the dispersive tail of the dispersionless Ablowitz–Ladik hierarchy.

A.1. Normal form for the D-operator. Since the D-operator maps densities to densities, the Hamiltonian flows it induces would be unmodified by the addition of a total derivative

\[ Df \rightarrow \tilde{D}f = Df + g' \]  

Moreover, since such densities are supposed to integrate to Hamiltonians of a dispersionless hierarchy, they will be bound to satisfy a linear wave equation of the form\(^{[103]}\).

Let us then give a normal form for the D-operator which solves this constraints. First of all, it was shown in\(^{[17]}\) that for systems of the type\(^{[103]}\), the coefficients \(b_{l,m}^{[k]}\) in\(^{[88]}\) can be taken to be independent of \(v\)

\[ b_{l,m}^{[k]}(v_x, \ldots, v^{(k)}, w \ldots, w^{(k)}) \] 

up to a total derivative. Let \(I \in \mathbb{N}^{2k}\) be such that

\[ \sum_{j=1}^{2k} \left[ \frac{j + 1}{2} \right] I_j = k \] 

The differential polynomial \(b_{l,m}^{[k]}\) explicitly reads

\[ b_{l,m}^{[k]} = \sum_{I} d_{I,l,m}(w) \prod_{j=1}^{k} (v^{(j)}(x))^{I_{2j-1}}(w^{(j)}(x))^{I_{2j}} \]
It is easy to realize that terms with $I_j = 0$ for $j > [(k + 1)/2]$ can be set to zero upon adding a suitable total derivative. The same is true for all remaining terms with $I_j = 1$ and $I_{j-2} = (k - [(j + 1)/2])/[(j - 1)/2]$ for $2 < j \leq [(k + 1)/2]$. This fixes entirely the ambiguity (161). Furthermore, we can take into account (103) by constraining $m \geq 1$; moreover, $\epsilon$-exactness of the Hamiltonian $H_{1,0}$ generating the space translations sets $n > 1$. We will take this as our normal form for the $D$-operator. The number of independent coefficients $N_k$ thus obtained at fixed $l$ and $m$, for the first few values of $k$, is $N_2 = 3$, $N_3 = 6$, $N_4 = 10$.

A.2. Computing the $D$-operator. Let us then give an example of how to compute the $D$-operator by outlining the computation of the 1-loop case for the Ablowitz–Ladik hierarchy. Let $f$ be an arbitrary dispersionless Hamiltonian density $H_{1,0}$. Then the $D^{[2]}$ correction to the $D$-operator should come from the $\mathcal{O}(\epsilon^2)$ involutivity condition

$$\left\{ H_{AL}^{[0]} + \epsilon^2 H_{AL}^{[2]}, \int_{S^1} (f + \epsilon^2 D^{[2]} f) dx \right\} = o(\epsilon^2)$$

i.e., at the level of the densities and using Lemma 3.4

$$\frac{\delta}{\delta v(x)} \left\{ h_{AL}^{[0]} + \epsilon^2 h_{AL}^{[2]}, f + \epsilon^2 D^{[2]} f \right\} = o(\epsilon^2) \quad (165)$$

$$\frac{\delta}{\delta w(x)} \left\{ h_{AL}^{[0]} + \epsilon^2 h_{AL}^{[2]}, f + \epsilon^2 D^{[2]} f \right\} = o(\epsilon^2) \quad (166)$$

These two variational equations give rise to an overdetermined linear system of coupled ODEs for the nine $d_{l,m}(w)$. Notice that the left-hand side is a differential polynomial which is linear in $\partial^n_v \partial^m_w f$. After enforcing (103), since $f$ has to be otherwise arbitrary, we can solve the system by imposing vanishing of the coefficient of each monomial $(\partial^n_v \partial^m_w f)$ $\prod_{j=1}^k (v^{(j)}(x))^{l_j-1} (w^{(j)}(x))^{l_j}$ for every $n, m, I$. It turns out that the first variational condition (165) is sufficient to solve for all coefficients. The strategy is to solve the equations starting from the highest non-vanishing value of $n$ (equal to 4 in this case), where the equations are linear algebraic in the coefficients $d$, and then express for lower $n$ all non-differentiated unknowns in terms of the others. With this criterion, the system (165) boils down to a second order ODE for a single $d_{n,m,I}$, which following this path of solution turns out to be $d_{2,0,0,2}(w)$, plus extra conditions which fully constrain the two constants of integration. The final answer is the one reported in (104). The same method generalizes straightforwardly, albeit resulting considerably heavier from a computational point of view, to the higher orders in $\epsilon$: at $\mathcal{O}(\epsilon^4)$ this method provides the expressions for $b^{[4]}_{vv}$ and $b^{[4]}_{vvv}$ we reported in (113)-(114).

Appendix B. Expansion formulae for hypergeometric functions

We give here some useful expansion formulae [34] for the expansion of Gauss’ hypergeometric function $2F_1(a, b; c; x)$ around integer values of $a$, $b$, and $c$. By hypergeometric recursions, this can be reduced to the following cases:

$$2F_1 \left( \begin{array}{c} 1 + a_1 c, 1 + a_2 c \\ 2 + c c \end{array} \right| z \right) = \frac{1 + cc}{z} \left( -\ln(1 - z) - \epsilon \left\{ \frac{c - a_1 - a_2}{2} \ln^2(1 - z) \\
+ c \text{Li}_2(z) \right\} + \epsilon^2 \left\{ (a_1 + a_2)c - c^2 - 2a_1a_2 \right\} S_{1,2}(z) + \left( (a_1 + a_2)c - c^2 - a_1a_2 \right) \ln(1 - z) \text{Li}_2(z) + c^2 \text{Li}_3(z) - \frac{1}{6}(c - a_1 - a_2)^2 \ln^3(1 - z) \\
- \epsilon^3 \left\{ c \left( (a_1 + a_2)c - c^2 - 2a_1a_2 \right) S_{2,2}(z) + c \left( (a_1 + a_2)c - c^2 - a_1a_2 \right) \right\} \right)$$
\[
\ln(1 - z) \operatorname{Li}_3(z) + (c - a_1)(c - a_2)(c - a_1 - a_2) \left[ \ln(1 - z) S_{1,2}(z) \\
+ \frac{1}{2} \ln^2(1 - z) \operatorname{Li}_2(z) \right] + \frac{1}{24} (c - a_1 - a_2)^3 \ln^4(1 - z) \\
+ c(c - a_1 - a_2)^2 S_{1,3}(z) + c^3 \operatorname{Li}_4(z) \right\} + \mathcal{O}(\epsilon^4),
\]

\[
\text{In } (167) \text{ and } (168), S_{n,p}(z) \text{ is the Nielsen generalized polylogarithm}
\]

\[
S_{n,p}(z) := \frac{(-1)^{n+p-1}}{(n-1)!p!} \int_0^1 \frac{\log^{n-1}(t) \log^p(1 - tz)}{t} \, dt
\]
