Interleukin (IL)-21 promotes intestinal IgA response to microbiota

AT Cao¹, S Yao¹, B Gong², RI Nurieva³, CO Elson⁴ and Y Cong¹,²

Commensal microbiota-specific T helper type 17 (Th17) cells are enriched in the intestines, which can convert into T follicular helper (Tfh) in Peyer’s patches, and are crucial for production of intestinal immunoglobulin A (IgA) against microbiota; however, the role of Th17 and Tfh cytokines in regulating the mucosal IgA response to enteric microbiota is still not completely known. In this study, we found that intestinal IgA was impaired in mice deficient in interleukin (IL)-17 or IL-21 signaling. IL-21, but not IL-17, is able to augment B-cell differentiation to IgA⁺ cells as mediated by transforming growth factor β1 (TGFβ1) and accelerate IgA class switch recombination (CSR). IL-21 and retinoic acid (RA) induce IgA⁺ B-cell development and IgA production and drives autocrine TGFβ1 production to initiate IgA CSR. Repletion of T-cell-deficient TCRβ⁻/⁻ mice with Th17 cells specific for commensal bacterial antigen increased the levels of IgA⁺ B cells and IgA production in the intestine, which was blocked by neutralizing IL-21. Thus IL-21 functions to strongly augment IgA production under intestinal environment. Furthermore, IL-21 promotes intestinal B-cell homing through α4β7 expression, alone or with TGFβ and RA. Together, IL-21 from microbiota-specific Th17 and/or Tfh cells contributes to robust intestinal IgA levels by enhancing IgA⁺ CSR, IgA production and B-cell trafficking into the intestine.

INTRODUCTION

The human intestinal tract is home to >100 trillion microorganisms, the majority of which reside peacefully without insult or challenge to the host. The mucosal surfaces are the most frequent access point for the microbiota, which is lined by a single layer of epithelial cells. Breach of the epithelial layer by pathogens results in enteric infections and disease, while chronic infiltration by the commensal microbiota leads to continued exposure and activation of the intestinal immune system.¹ Over time, chronic and dysregulated immune responses against the commensal microbiota results in increased inflammation and the onset of inflammatory bowel disease.² Among the multiple regulatory mechanisms regulating host response to microbiota, immunoglobulin A (IgA), which is enriched in mucosal secretions, has crucial roles in the maintenance of intestinal homeostasis against microbiota. IgA functions to neutralize and aid in clearance of extracellular pathogens by preventing adherence to epithelial surfaces and limiting access to the intestines and the immune system.³ The high level of IgA production is driven by microbial colonization of the intestine, as germ-free mice have low levels of IgA and IgA⁺ B cells, whereas colonization with commensal bacteria restores IgA production,⁴ and the majority of intestinal plasmablasts produce antibodies that are specific for intestinal antigens.⁵ Notably, monoclonization of germ-free mice with segmented filamentous bacteria (SFB) selectively increases IgA production and secretion,⁶ and intestinal IgA deficiency in mice leads to SFB overgrowth.⁷ A recent report revealed that colonization by SFB induced both IgA⁺ B cells and T helper type 17 (Th17) cells in multiple locations in the intestine.⁸ With the observations that SFB colonization can control both Th17 cells and IgA production, it therein suggests a link between intestinal T-cell function and IgA production.

As with all subtypes of CD4⁺ T cells, Th17 and T follicular helper (Tfh) cells exhibit influence over B-cell responses. Transfer of Th17 cells into T-cell-deficient TCRζ⁻/⁻ mice results in increased serum IgG titers across all measured subtypes (IgG1, IgG2a, IgG2b, and IgG3), with the strongest increases in IgG1 and IgG2b.⁹ Furthermore, transfer of Th17 cells induces the generation of germinal centers (GCs) in the

spleen and draining lymph nodes, structures that are mostly lacking in the absence of T cells. These effects are dependent on both IL-17 and IL-21, as transfer of Th17 cells into IL-17α−/− or IL-21R−/− mice do not increase the number of GCs present.

Direct addition of IL-17 to B cells in vitro triggers the production of IgG2a and IgG3, whereas IL-21 induces production of IgG1, IgG2a, IgG2b, and IgG3, indicating that sources of IL-21 and IL-17 are competent B-cell helpers in generating systemic IgG responses. The effects of IL-17 and IL-21 on IgG induction is further demonstrated in the role of IL-17 during systemic lupus erythematosus, characterized by autoreactive B cells and pathogenic autoantigen antibody production. Patients with systemic lupus erythematosus have increased serum levels of IL-17, IL-21, and B cell-activating factor belonging to the TNF system, which promote survival and antibody production from autoantigenic B cells.10–13 We recently demonstrated that intestinal Th17 cells promote secretory IgA response through IL-17 stimulation of intestinal epithelial expression of polymeric Ig receptor.14 A recent report further demonstrates that Th17 cells convert into Tfh cells in Peyer’s patches and induce intestinal IgA.15 It has been shown that IL-21 can modulate B-cell differentiation by enhancing IL-4-driven IgG production and transforming growth factor β (TGFβ)-driven IgA production.16 However, whether Th17 and Tfh cell cytokines directly influence mucosal IgA production has not been fully investigated. In this report, we demonstrate that IL-21, produced by both Th17 and Tfh cells, can augment IgA responses mediated by TGFβ1 and retinoic acid (RA) in the intestine, and intestinal sources of IL-21 directly induce IgA production.

RESULTS
IL-21 but not IL-17 promotes intestinal B-cell production of IgA
CD4+ T cells have an important role in the induction of IgA in the intestine, as T-cell-deficient TCRβΔ−/− mice have significantly lower amounts of fecal IgA.18 Our previous work has detailed an important role for Th17 cells in the regulation of the intestinal IgA response through induction of pIgR expression on intestinal epithelial cells as mediated by IL-17.14 Th17 cells produce high levels of IL-17, IL-21, and IL-22.19,20 B cells do not express the IL-22 receptor,21,22 so we investigated the roles of IL-17 and IL-21 in the intestinal IgA response. Analysis of fecal IgA levels between wild-type and IL-17−/− mice demonstrate decreased levels of intestinal IgA (data not shown) as previously published.14 We further determined the role of IL-21 in the intestinal IgA response by analyzing IgA levels in mice deficient in IL-21 signaling. Quantification of fecal IgA from IL-21−/−, IL-21R−/− and wild-type mice revealed a significant decrease in IgA levels in the absence of IL-21 signaling (Figure 1a), demonstrating that IL-21 regulates intestinal IgA production.

Given that the separate absence of both IL-17 and IL-21 resulted in deficiencies in the intestinal IgA response, we then investigated whether IL-17 and IL-21 could directly stimulate B cells to produce IgA. We isolated splenic naive IgD+ B cells and cultured them with anti-μ and CD40L for B-cell activation to mimic T-cell contact, together with TGFβ1 in the presence or absence of IL-17 or IL-21. IgA in the supernatant was measured by enzyme-linked immunosorbent assay (ELISA) and normalized to total protein. N=2 mice per group; data are reflective of two independent experiments. *P<0.05 compared with wild-type mice. (b) Naive IgD+ B cells were activated with anti-μ (5 μg ml−1) and anti-CD40 (5 μg ml−1) in the presence of TGFβ1 (5 ng ml−1), IL-17 (50 ng ml−1), IL-21 (20 ng ml−1), or RA (1 μm) or a combination of TGFβ1, IL-17, IL-21, and/or RA. On day 5, IgA was measured from the supernatant by ELISA. Data are reflective of six independent experiments. *P<0.05, ***P<0.001 compared between samples. +P<0.05, ++P<0.01 compared with untreated cells.

**Figure 1** Interleukin (IL)-21 regulates immunoglobulin A (IgA) production in cooperation with transforming growth factor β (TGFβ) and/or retinoic acid (RA). (a) Fecal pellets were collected from age-matched wild-type, IL-21−/−, and IL-21R−/− B6 mice. IgA levels were quantified through enzyme-linked immunosorbent assay (ELISA) and normalized to total protein. N=2 mice per group; data are reflective of two independent experiments. *P<0.05 compared with wild-type mice. IL-21 augments TGFβ-mediated IgA class switch recombination (CSR)
It has been shown that IL-21 is able to modulate B-cell differentiation by enhancing IL-4-driven IgG production14 and TGFβ-driven IgA production.17 We then investigated the mechanisms by which IL-21 regulates B-cell IgA production. In order for B cells to fully differentiate, activated B cells undergo CSR, by which the Ig heavy chain locus becomes rearranged and portions of the locus become looped-out and excised from the genome. The physical recombination of the Ig locus is facilitated by the enzyme activation-induced cytokine deaminase (Aicda).23 B cells undergo IgA CSR after exposure to TGFβ1, and the loci for IgG, IgE, and IgM are removed from the genome. These B cells are permanently differentiated and can only produce IgA. CSR is a rapid process; however, the looped-out chromosomes stay within the cell for 24–48 h.24 and
To determine whether IL-21 can induce CSR, splenic B cells were cultured with anti-μ (5 μg ml⁻¹) and anti-CD40 (5 μg ml⁻¹) in the presence of TGFβ1 (5 ng ml⁻¹) or IL-21 (20 ng ml⁻¹) or RA (1 μM) and a TGFβ1 receptor I inhibitor (1 μM). RNA was collected from cultured B cells after 3 days, and 2 μg RNA was used to analyze molecular markers for IgA CSR by reverse transcription–PCR. CT, circular transcripts; GLT, germ-line transcripts. Image is representative of three independent experiments. (b) Naive IgD⁺ B cells were activated with anti-μ and anti-CD40 in the presence of IL-21 and/or RA. On day 5, supernatant was collected from cultured B cells as a conditioned medium. To detect bioactive TGFβ1, the TGFβ1-reporter cell line MFB-F11 was cultured with B-cell-conditioned medium for 24 h. Secreted alkaline phosphatase was measured as a reflection of TGFβ1 bioactivity. Data are reflective of four independent experiments. *P<0.05, **P<0.01 compared with conditioned medium from untreated B cells.

As RA and IL-21 also increased IgA production in the absence of exogenous TGFβ1, we next investigated how IL-21 and RA regulate IgA production. Analysis of the mRNA transcripts revealed that IL-21 and RA together were capable of inducing an overall IgA response, particularly at the germ-line transcriptional level (Figure 3a). Interestingly, we were able to detect CT in B cells treated with IL-21 and RA, without exogenous TGFβ1. Treatment of B cells with IL-21, RA, and a TGFβ receptor I inhibitor (SB505124) negated the IgA CSR process, revealing that IL-21 and RA stimulation of IgA-secreting B-cell development is still reliant upon TGFβ1, which could be mediated by enhancing B-cell response to TGFβ or promoting B-cell production of TGFβ.

We sought to determine whether IL-21 and RA signals were able to modulate the B-cell response to TGFβ. Although the naive B cells continued to produce IgA in the absence of exogenous TGFβ, there remained some TGFβ in the culture as a result of medium supplemented with fetal bovine serum. However, IL-21 and RA (separately or in tandem) did not increase B-cell expression of tgfbr1 or tgfbr2 (data not shown), and thus they did not influence B-cell sensitivity to TGFβ1. Our previous work has demonstrated that RA induces dendritic cell TGFβ1 production, resulting in increased regulatory T-cell differentiation in the intestine.28 We then investigated whether IL-21 and RA could induce B-cell production of TGFβ and
therefore drive IgA CSR. Consistently, we revealed that RA has a similar effect in B cells, in that RA is able to induce TGFβ production from B cells. Although IL-21 has little effect on TGFβ induction, it appears to promote RA-induced TGFβ production (Figure 3b). Appropriately, the induction of TGFβ by RA, and synergism with IL-21 is sufficient to drive IgA production in the absence of exogenous TGFβ1.

Transfer of Th17 cells promote IgA⁺ B-cell development in the intestinal lamina propria but not in the spleen of TCRβδ⁻/⁻ mice

Thus far, our results in vitro have demonstrated that IL-21 promotes B-cell development towards IgA production. As Th17 cells produce IL-21, in addition to IL-17, we then transferred Th17 cells into TCRβδ⁻/⁻ mice, which contain B
cells but lack T cells, to determine whether they can affect intestinal IgA⁺ B-cell development and B-cell IgA production in vivo, and whether IL-21 was required for their action. We generated Th17 cells from microbiota antigen CBir1-specific T-cell receptor (TCR) transgenic mice\textsuperscript{29} in vitro and transferred them into TCRβxδ⁻/⁻ mice and treated them with a neutralizing antibody against the IL-21 receptor (IL-21r).

Recipient mice were killed 44 days after transfer, and frequencies of IgA⁺ B cells were measured in the spleen and intestines. Antibody levels were also measured from feces and serum and compared with naive TCRβxδ⁻/⁻ mice. Transfer of Th17 cells did not significantly increase populations of IgA⁺ B220⁺ cells in the spleen; however, both frequencies and the total population of IgA⁺ B220⁻ plasma cells were increased in the spleen (Figure 4a,b). Blockade of IL-21 signaling did not affect the levels of both IgA⁺ B220⁺ and B220⁻ cells. Analysis of intestinal B cells revealed greater numbers of IgA⁺ B cells in the lamina propria of intestines (Figure 4a,b) after Th17 cell transfer. Within the intestinal lamina propria, the levels of both IgA⁺ B220⁺ and B220⁻ plasma cells were significantly increased. Notably, blockade of IL-21 primarily decreased populations of IgA⁺ plasma cells but had no discernible effect on IgA⁺ B220⁻ cells. This remained consistent with B-cell populations within the Peyer’s patches, as Th17 cell transfer increased IgA production from B220⁺ and B220⁻ cells; however, blockade of IL-21 reduced IgA⁺ plasma cell populations without affecting B220⁻ cells. Consistently, transfer of Th17 cells increased serum IgA when compared with naive TCRβxδ⁻/⁻ mice (Figure 5a), which was slightly attenuated by blockade of IL-21r. Levels of IgG in the serum also increased significantly after Th17 cell transfer. Notably, blockade of IL-21 increased serum IgG, likely indicating a role for IL-21 in the switching from IgG to IgA production (Figure 5a). Th17 cells were capable of inducing strong intestinal IgA responses as measured from 2 weeks after Th17 cell transfer (Figure 5b), which is consistent with previous reports.\textsuperscript{14,15} Blockade of IL-21r decreased the IgA levels in the feces, consistent with the decrease in IgA-secreting plasma cells. Given that we used CBir1 Tg Th17 cells that respond to the immunodominant bacterial flagellin CBir1,\textsuperscript{18} the transferred T cells would become activated and exhibit effector function after migrating to the intestine and encountering the intestinal antigens. That may in part explain why we observe that the expansion in B220⁺ cells primarily occurs in the intestine. The resulting plasma cells appear to re-enter circulation in the spleen. Furthermore, IgA⁺ cells were found in the bone marrow of Th17 cell recipients, whereas the bone marrow of naive TCRβxδ⁻/⁻ mice did not contain IgA-producing cells. IgA⁺ B220⁻ CD138⁺ plasma cells migrated into or were formed in the bone marrow after Th17 cell transfer. We also found a population of IgA⁺ B220⁺ CD38⁺ cells in the bone marrow, which could be partially comprised of memory B cells. Blockade of IL-21 did not have an effect on IgA⁺ B-cell populations in the bone marrow (Figure 5c). Although IL-21 was important for plasma cell generation in the periphery and the intestines, IL-21 did not contribute to plasma cell populations in the bone marrow, possibly indicating that bone marrow plasma cells were generated in the periphery and entered the bone marrow, or the neutralizing antibodies were limited in penetrating the bone marrow.\textsuperscript{30} Consistently, the increased levels of IgA results in both increased secretion into the intestinal lumen, as well as increased circulation in the serum, to which IL-21 contributes.
GC reactions are critical for T-dependent antibody responses. It has been shown that IL-17 and IL-21 non-redundantly contribute toward GC formation within the lymphoid tissues.9 Within naïve TCRβδ−/− mice, we found no evidence of germinal B cells based on co-expression of GL7 and CD95. GC B cells were increased after transfer of Th17 cells (Figure 6a). We found the highest incidences of GCs within the mesenteric lymph node and Peyer’s patches. With the associated increase in GC B cells (Figure 6a), we observed that structured GCs had developed in the Peyer’s patches of Th17 cell recipients (Figure 6b). Consistent with previously described roles for IL-21,9,27 we found that neutralizing IL-21r decreased the frequencies of GC B cells in both the mesenteric lymph node and Peyer’s patches; however, frequencies remained higher than those found in naïve TCRβδ−/− mice (Figure 6a). B cells in the intestinal lamina propria also reflected a small number of GC B cells; however, we were unable to detect active IgA class switching in the intestinal tissue. Further, Aicda expression was not significantly changed after Th17 cell transfer (Figure 6c). Collectively, these data indicated

Figure 6  Transfer of CBir1 T helper type 17 (Th17) cells into TCRβδ−/− mice induces germinal center formation in the intestinal lymphoid tissues. In all, 10^6 CBir1 Th17 cells were intravenously transferred into TCRβδ−/− mice. (a) On day 44 post-Th17 cell transfer, the expression of germinal center markers GL-7 and CD95 on splenic, mesenteric lymph node (MLN), intestinal lamina propria, or Peyer’s patch (PP) B220+ cells of CBir1 Th17 cell recipients, Th17 cell recipients receiving neutralizing interleukin (IL)-21r (Th17+ αIL-21r), or control TCRβδ−/− mice was determined by flow cytometry. Fluorescence-activated cell–sorted plots are representative of four mice per group. (b) Immunofluorescence image of PP from control TCRβδ−/− mice or CBir1 Th17 cell recipients with 20 objective. Germinal center formation was analyzed by staining for GL-7-AlexaFluor 594 and B220–fluorescein isothiocyanate. (c) RNA was collected from ileal tissue on day 44 post-Th17 cell transfer from CBir1 Th17 cell recipients or control TCRβδ−/− mice, and Aicda mRNA was analyzed by reverse transcription–PCR. Data are reflective of four mice per group from three independent experiments. LPL, intestinal lamina propria lymphocytes.
that the intestinal lamina propria was not the primary site for IgA induction.

Follicular T cells are also a substantial source of IL-21 and are abundantly present in the lymphoid tissues. It has been recently discovered that Th17 cells can undergo conversion into Tfh in the Peyer’s patches, where they produce IL-21 and drive IgA responses. We therefore investigated whether our transferred Th17 cells were converting into Tfh in the intestines. We found that the transferred Th17 cells retained IL-17 and retinoic acid–related orphan receptor γt (RORγt) expression throughout the spleen and intestines, including the Peyer’s patches. Notably, the intestinal lamina propria contained the highest populations of Th17 cells (Figure 7a). Many of the transferred cells also expressed IL-21, either independently or in tandem with IL-17. Few of the transferred cells co-expressed programmed cell death protein 1 (PD-1) and C-X-C motif chemokine receptor 5 (CXCR5), the characteristic surface markers of Tfh cells; however, those cells also retained IL-17 and RORγt expression (Figure 7b). Consistent with the previous report, the Peyer’s patches had the highest frequencies of transferred cells expressing Tfh markers; however, these cells did not completely lose IL-17 production. It is notable that the Peyer’s patches had the overall lowest frequency of IL-17+ cells.

Figure 7  Transferred CBir1 T helper type 17 (Th17) cells into TCRβδ−/− mice retain interleukin (IL)-17 and retinoic acid–related orphan receptor γt (RORγt) expression. In all, 10^6 CBir1 Th17 cells were intravenously transferred into TCRβδ−/− mice. (a) On day 44 post-Th17 cell transfer, analysis of IL-17, IL-21, RORγt, PD-1, and C-X-C motif chemokine receptor 5 (CXCR5) expression on the spleen, mesenteric lymph node (MLN), intestinal lamina propria, or Peyer’s patch (PP) CD4 T cells of CBir1 Th17 cell recipients was determined by flow cytometry. (b) Analysis of IL-17 and RORγt expression from PD-1+ CXCR5+ CD4 T cells of CBir1 Th17 cell recipients was determined by flow cytometry. Fluorescence-activated cell–sorted plots are representative of four mice per group. LPL, intestinal lamina propria lymphocytes.
IL-21 induces mucosal homing on B cells

It has been shown that RA is able to induce the expression of homing molecules on lymphocytes to migrate to the intestinal tract.\textsuperscript{28,31} We then questioned whether IL-21 could synergize with RA to influence B-cell mucosal homing through induction of $\alpha_4\beta_7$, thus concentrating to Th17 cell induction of intestinal IgA production. Ligation of $\alpha_4\beta_7$ on lymphocytes with mucosal addressin cell adhesion molecule 1 on endothelial vessels results in lymphocyte migration into the intestinal tract. We cultured splenic B cells with anti-\mu and CD40L in the presence or absence of TGF\(\beta\)1 and IL-21, alone or in combination, with or without RA to determine whether Th17 cell cytokines could induce B-cell expression of $\alpha_4\beta_7$. Five days after culture, cells were analyzed for $\alpha_4\beta_7$ expression via fluorescence-activated cell sorter. As expected, RA was able to induce $\alpha_4\beta_7$ expression, which was enhanced with TGF\(\beta\)1 (Figure 8). Interestingly, IL-21 alone was able to induce $\alpha_4\beta_7$ expression, which was enhanced with both TGF\(\beta\)1 and RA. Although the synergy between IL-21 and RA was not quite to the degree as TGF\(\beta\)1 and RA, the combination of all three molecules resulted in optimal $\alpha_4\beta_7$ expression, concomitant with IgA production as seen in Figure 1b. Notably, IL-17 had no visible effect on $\alpha_4\beta_7$ induction, both alone and in conjunction with RA (data not shown). These data indicate that IL-21 contributes to mucosal homing in addition to IgA production in conjunction with TGF\(\beta\)1 and RA.

DISCUSSION

The gastrointestinal tract exists in a mutualistic relationship with the commensal flora within. Multiple mechanisms have evolved to regulate and conserve homeostasis between the immune system and microbiota. The intestines act as a natural reservoir for IgA-producing B cells, where they are critical for maintaining intestinal homeostasis by containing the vast population of commensal bacteria. Our data demonstrated that Th17 cells and their cytokine IL-21 in the intestine strongly promote intestinal IgA production by promoting differentiation of B cells to IgA-secreting cells. Furthermore, IL-21 can influence B cells to migrate into the intestine, where they can continue to differentiate into IgA-secreting cells.

Regulatory T, Th17 and Tfh cells have all been shown to promote the IgA response in the intestine.\textsuperscript{14,15,18} Both Th17 and Tfh cells produce IL-17A and IL-21,\textsuperscript{19,32} cytokines that are important for establishing GC architecture and thus the humoral response. Further, IL-21 induces B cells to undergo CSR and produce large amounts of IgG.\textsuperscript{9} TGF\(\beta\) can override IL-21-mediated CSR to IgG in favor of class switching to IgA in mucosal tissues.\textsuperscript{27} IL-21 has also been described to have a number of pro-B-cell effects, which may contribute to increasing IgA production, particularly during T-dependent antibody responses. Both RA and IL-21 promote overall B-cell proliferation,\textsuperscript{33–35} as well as selected proliferation of TGF\(\beta\)-mediated IgA\(^+\) cells.\textsuperscript{23,27} In our current study, our results indicate that IL-21 is a potent inducer of CSR, as indicated by Aicda transcription and, when combined with TGF\(\beta\)1, results in highly specific and accelerated induction of CSR to promote IgA-secreting B cells. It remains notable that RA is required to achieve optimal IgA induction from IL-21-treated B cells \textit{in vitro}. Furthermore, it is likely that IL-21 from Th17 cells synergizes with physiological RA and TGF\(\beta\) to drive intestinal IgA production \textit{in vivo}. This may indeed help to explain the mechanism by which the intestinal environment is so favorable for IgA\(^+\) B cells. As described previously, the intestinal environment is rich in molecular cues, including TGF\(\beta\) and RA,

\textbf{Figure 8} Interleukin (IL)-21 induces mucosal homing markers alone and in synergism with transforming growth factor \(\beta\)1 (TGF\(\beta\)1) and/or retinoic acid (RA). Naive IgD\(^+\) B cells were activated with anti-\mu (5 \(\mu\)g ml\(^{-1}\)) and anti-CD40 (5 \(\mu\)g ml\(^{-1}\)) and cultured with TGF\(\beta\)1 (5 ng ml\(^{-1}\)) and IL-21 (20 ng ml\(^{-1}\)), alone or in combination, with or without RA (1 \(\mu\)M). On day 5, $\alpha_4\beta_7$ was measured by flow cytometry. Fluorescence-activated cell–sorted plots are representative of three independent experiments. NT, no treatment.
to promote IgA production and differentiation. As such, our data further reveal that, in the intestinal environment with high levels of TGFβ and RA, Th17 and Tfh cell production of IL-21 is capable of inducing strong IgA+ B-cell differentiation and IgA production from B cells.

It is interesting to note that IL-21 and RA are capable of inducing IgA production in the absence of exogenous TGFβ1 (Figure 1b). Our previous work has detailed an important role for RA in the maintenance of the intestinal regulatory T-cell population.28 Intestinal dendritic cells are able to produce TGFβ after exposure to RA, which in turn induces Foxp3 expression in CD4+ T cells and promotes regulatory T-cell differentiation. As shown in Figure 3b, RA also stimulates B cells’ production of TGFβ. As B cells have already been described to have regulatory roles through production of IgA and IL-10,15,16 our findings broaden their regulatory roles, specifically that B cells are capable of directing their own differentiation into IgA-secreting cells. Although IL-21 alone does not induce TGFβ production from B cells, it appears to promote RA-induced TGFβ production, which is consistent with the role of IL-21 in promoting IgG responses rather than IgA. The observation that IL-21 and RA can cooperate in the regulation of B-cell homing to intestines through αββ, suggests that Th17 and Tfh cells can indirectly regulate the development of IgA+ B cells outside of the intestinal tract. Environments such as the bone marrow are rich in RA and IL-21 and may influence naïve B cells from the bone marrow to migrate en masse to the intestines, where the environment is ripe for the induction of IgA+ B cells. Interestingly, IL-17 and IL-21 differentially regulate intestinal IgA response in a cooperative manner.

The primary observation that IL-21 can promote IgA+ B cells appears to occur primarily in the intestinal tract. After transferring Th17 cells into naïve TCRβδ−/− mice, we observed a strong increase in IgA+ cells in the periphery and intestines; however, blockade of IL-21 only decreased IgA+ cells in the intestines. Accordingly, blockade of IL-21 led to a decrease in fecal IgA, while it did not significantly decrease serum IgA. This indicates that: (1) IL-21 augments the favorable environment for promoting IgA responses in the intestine; and (2) IL-21 may provide an important switch for B cells to produce IgA rather than IgG. Previous reports have indicated that Th17 cells produce IL-21 and support IgA production only after conversion into Tfh cells15 in the Peyer’s patches. However, we found that our Th17 cells retained IL-17 and RORγt expression 7 weeks after transfer. Transferred cells also expressed IL-21, while lacking PD-1 and CXCR5 co-expression, suggesting limited conversion to Tfh cells. Although the Th17-to-Tfh conversion described by Hirota et al.15 was observed after 3 months, we found few PD-1/CXCR5 co-expressing cells in the Peyer’s patches after 7 weeks. It remains possible that Th17 reprogramming is an extended process as the Peyer’s patches contained fewer IL-17+ cells than those in the lamina propria or mesenteric lymph node; however, we observed an increase in fecal IgA within 2 weeks after Th17 cell transfer, indicating that Th17 cells are competent in supporting IgA production.

Although TGFβ1 is required for CSR to IgA, a number of other factors can facilitate and modify IgA production or IgA+ cell differentiation. Previous studies have indicated that TGFβ can also induce IgG2b production; however, IL-21 appears to inhibit IgG2b production and skews toward IgA class switching.17 Although our results concur on the final differentiation pattern of IgA+ B cells, we present a more rapid and efficient differentiation pattern. The increased robustness of our IL-21 treatment may be a result of the differing activation strategies; Seo et al.17 utilized T-independent activation via LPS, whereas our experiments used anti-CD40 and anti-μ antibodies in order to focus on a T-dependent mechanism. As such, our results remain consistent with observations made in human mucosal tissues, such that IL-21 can greatly increase activation-induced cytidine deaminase and IgA production in conjunction with TGFβ treatment.27 Previous evidence has demonstrated that IgA class switching primarily occurs in the Peyer’s patches but can occur in the intestinal lamina propria.3 These studies revealed that both T-dependent and T-independent responses could occur in the intestinal lamina propria of normal mice and humans.19,20 Although we observed the expression of Aicda in the intestines of naïve TCRβδ−/− mice, the expression was neither enhanced by the presence of Th17 cells nor was the genetic evidence of IgA class switching detected, despite the high numbers of IgA+ plasma cells in the lamina propria.

In summary, our current study demonstrates that IL-21, which is produced by Th17 and Tfh cells that are particularly enriched in the intestinal lamina propria, promote IgA+ B-cell differentiation and IgA production in the intestinal environment that contains high levels of TGFβ and RA. IL-21 directly induces B-cell IgA CSR to promote IgA-secreting B cells and B-cell IgA production, whereas IL-17 stimulates plgR expression in epithelial cells, thereby enhancing IgA translocation into the intestinal lumen. Thus IL-21 and IL-17 coordinately regulate intestinal IgA response to microbiota.

MATERIALS AND METHODS

Mice. TCRβδ−/− mice were obtained from Jackson Laboratory (Bar Harbor, ME). CBir1 flagellin-specific TCR transgenic (CBir1-Tg) mice were maintained in the Animal Facilities at University of Texas Medical Branch. All experiments were reviewed and approved by the Institutional Animal Care and Use Committees of the UTM and the MD Anderson Cancer Center. All the mice strains were bred in the UTM animal facility and housed together from 3 weeks of age. IL-21−/− and IL-21r−/− mice were maintained at the Animal Facilities at MD Anderson Cancer Center. All mice are bred onto the C57BL/6 background and contain SFB as verified via PCR. Eight-to-12-week-old mice were used for all experiments.

Antibody and reagents. The following antibodies were used for flow cytometry: PE-IL-17A (TC11-18H10.1), FITC-B20 (RA3-682), PE-zαβ, (DATK32), FITC-CD4 (RM4-5), PE/Cy7-CD38 (90), APC-CD138 (281-2), and PE/Cy7-PD-1 (29 F.1A12) were purchased from Biolegend (San Diego, CA); APC-RORγt (B2D), APC-GL-7, and eFluor450-Streptavidin were from eBioscience (San Diego, CA); Brilliant Violet 421-CD95 (Jo2) and biotinylated CXCR5 (2G8) were from BD Biosciences (San Diego, CA); recombinant mouse IL-21 R human FC chimera was from R&D Systems (Minneapolis, MN); AlexaFluor 647 anti-human IgG FC (polyclonal) was from Jackson ImmunoResearch Laboratories (West Grove, PA) and PE-IgA

VOLUME 8 NUMBER 5 | SEPTEMBER 2015 | www.nature.com/mi
Intracellular permeabilization was performed with the FixP3 Perm/Fix Kit from eBioscience. Live cells were gated using Live/Dead Fixable Dead Cell Stain Kit from Life Technologies (Carlsbad, CA). Mouse recombinant IL-6 and human recombinant IL-17A and TGFβ1 were purchased from R&D Systems. Recombinant IL-21 was purchased from eBioscience. Antibody against IL-21r (4A9) was from BioXCell (West Lebanon, NH). Antibodies against IgA and IgD were purchased from Kirkegaard & Perry Labs (Gaithersburg, MD) and Southern Biotechnology. Anti-μ was purchased from Jackson ImmunoResearch Laboratories. All-trans-RA, TGFβ receptor I inhibitor SB505124, and collagenase IV were purchased from Sigma-Aldrich (St Louis, MO). Anti-biotin microbeads from Miltenyi (San Diego, CA) were used to sort naïve IgD+ B cells.

**Polarization of Th17 cells.** CD4+ T cells were isolated from the spleens of CBir1 Tg mice using anti-mouse CD4-magnetic beads (XMG1.2, BioXCell), and 10 μg ml⁻¹ anti-IFNγ (XMGI.2, BioXCell), and 10 μg ml⁻¹ anti-IL-4 (11B11, BioXCell) with irradiated splenic allogeneic.29

**Fecal pellet preparation.** Fecal pellets were homogenized in phosphate-buffered saline containing 0.04 mg ml⁻¹ soybean trypsin inhibitor, 20 mM EDTA, and 2 mM phenylmethanesulfonylfluoride and centrifuged to remove bacteria and insoluble debris as described previously.42

**Enzyme-linked immunosorbent assay.** Ninety-six-well plates (Nunc, Waltham, MA) were coated with 1 μg ml⁻¹ anti-IgA (Kirkegaard & Perry Labs) overnight at 4 °C, blocked in phosphate-buffered saline with 1% bovine serum albumin, and incubated with sera or fecal pellets for 2 h. After washing, adherent antibodies were detected by biotinylated anti-IgA or anti-IgG, followed by horseradish peroxidase-labeled streptavidin. Plates were developed using 3,3',5,5'-tetramethylbenzidine and analyzed at 450 nm.

**Intestinal lamina propria isolation.** As described previously,18 intestines were removed, and the Peyers’ patches were excised. Intestines were sliced and incubated with 50 μM EDTA to remove epithelial cells. Intestines were then digested by collagenase IV. Liberated cells were resuspended in 40% Percoll and overlaid onto 70% Percoll. The interface containing lymphocytes was collected. Lymphocytes were directly stained (for B cells) or restimulated with phorbol myristate acetate containing lymphocytes was collected. Lymphocytes were directly

**TGFβ bioassay.** As described previously,28 MFB-F11 cells are embryonic fibroblasts from Tgfb1-/− mice that are stably transfected with germ-line transcripts, and anti-IgM (Kirkegaard & Perry Labs) from Kirkegaard & Perry Labs (Gaithersburg, MD) and Southern Biotechnology. Anti-CD4 was from Southern Biotechnology (Birmingham, AL). Recombinant IL-21 was purchased from R&D Systems. Recombinant IL-6 and human recombinant IL-17A and TGFβ1 were purchased from Sigma-Aldrich (St Louis, MO). Anti-biotin microbeads from Miltenyi (San Diego, CA) were used to sort naïve IgD+ B cells.

**Quantitative real-time/reverse transcription PCR**. RNA was extracted with TRIzol (Invitrogen, Carlsbad, CA) and followed by cDNA synthesis with Revertaid Reverse Transcriptase (Fermentas, Pittsburgh, PA). Quantitative PCR was performed using the TaqMan Gene Expression Assays. Predesigned primers and probes for Aicda and Gapdh were ordered from Applied Biosystems (Carlsbad, CA), and data were normalized to Gapdh mRNA expression. To detect germ-line α transcripts, the primers IgF (5’-CCAGGCGATGTTTG AGATAGAGATAG-3’) and CqR (5’-AAGTGGCAGGGGAGGAAGT3’) were used. CT were determined by a nested PCR and probes ordered from Applied Biosystems (Carlsbad, CA), and followed by 18S rRNA expression and 16S rRNA expression.

**Immunofluorescence.** Deparaffinized and rehydrated Peyer’s patch sections were incubated for an hour with biotinylated-GL-7 (eBioscience) and FITC-B220 (clone RA3-6B2, Biolegend), followed by incubation with AlexaFluor 594-streptavidin (Jackson ImmunoResearch Laboratories). Images were taken and analyzed with an Olympus BX51 imaging system (Center Valley, PA).

**Statistical analysis.** For comparisons between samples, the levels of significance were determined by Student’s t-test in Prism 5.0 (Graphpad, La Jolla, CA). Where appropriate, mean ± s.e.m. is represented on graphs.

**ACKNOWLEDGMENTS** We thank Mats Bemark and Peter Bergqvist of the University of Gothenburg, Sweden for critical advice in the detection of IgA CSR, γ germ-line transcripts, and α postswitch transcripts. This work was supported by NIH grants DK079918 and DK098370 and John Sealy Memorial Endowment Fund. A.T.C. is a recipient of the J.W. McLaughlin Postdoctoral Fellowship, UTMB.

**DISCLOSURE** The authors declared no conflict of interest.
