Abstract

The axis compensation is a procedure in which the sender and the receiver compensate the axes of their transmitter and detector so that the bit sequence can be transmitted more reliably. We show the optimal axis compensations maximizing the key generation rate for unital channels. We consider the case in which only Bob is allowed to compensate his axis, and the case in which both Alice and Bob are allowed to compensate their axes. In the former case, we show that we should utilize the mismatched measurement outcomes in the channel estimation phase. In the latter case, we show that we do not have to utilize the mismatched measurement outcomes in the channel estimation phase.

1 Introduction

Quantum key distribution (QKD) has attracted great attention as a technology to realize the information theoretically secure key agreement. In this paper, we investigate the Bennett-Brassard 1984 (BB84) protocol [1] and the six-state protocol [2], and the QKD protocols indicate the BB84 protocol and the six-state protocol.

Typically in theoretical studies on the QKD protocols, the protocols roughly consist of three phases: the bit transmission phase, the channel estimation phase,
and the postprocessing phase. In the bit transmission phase, the legitimate sender, usually referred to as Alice, sends a bit sequence to the legitimate receiver, usually referred to as Bob, by encoding them into qubits. In the channel estimation phase, Alice and Bob estimate the channel and the amount of information gained by an eavesdropper, usually referred to as Eve. Finally in the postprocessing phase, Alice and Bob share a secret key based on their bit sequences obtained in the bit transmission phase.

On the other hand, in the practical QKD protocols, Alice and Bob conduct the axis compensation (before the bit transmission phase), in which Alice and Bob compensate the axes of their transmitter and detector so that the bit sequence can be transmitted more reliably in the bit transmission phase. This axis compensation is considered to be indispensable in the QKD protocols, and it has been extensively studied from the experimental point of view [3, 4, 5, 6, 7, 8, 9] (see also [10]). However, it has not been theoretically clarified how Alice and Bob should compensate the axes in the axis compensation.

In this paper, we investigate the optimal axis compensation in the sense that the key generation rate is maximized, where the key generation rate is defined as the ratio between the length of the shared secret key and that of the sequences initially possessed by Alice and Bob in the postprocessing phase.

We consider the following various settings. In the channel estimation phase, we consider two kinds of channel estimation: the accurate channel estimation and the conventional channel estimation (see [11]). In the accurate channel estimation, we use the mismatched measurement outcomes, which are bits transmitted and received by different bases, in addition to the matched measurement outcomes, which are bits transmitted and received by the same bases, to estimate the channel. On the other hand, in the conventional channel estimation, we discard the mismatched measurement outcomes and only use the matched measurement outcomes. The reason why we consider two kinds of channel estimation is that the authors recently clarified that the key generation rate is increased if we use the accurate channel estimation instead of the conventional channel estimation [11]. It is worthwhile to clarify whether we should use the accurate channel estimation instead of the conventional channel estimation when the QKD protocols involve the axis compensation.

In the postprocessing phase, we employ the standard postprocessing. We do not use the noisy preprocessing [12] nor the two-way classical communication [14] [15].

In the axis compensation phase, we consider two kinds of compensations:

(i) (one-side compensation) Only Bob is allowed to compensate his axis.

(ii) (two-side compensation) Both Alice and Bob are allowed to compensate their axes.

Furthermore in the BB84 protocol, we subdivide each compensation into two kinds. In the first kind, Bob (or both Alice and Bob) is allowed to compensate
his axis within the z-x plane of the Bloch sphere. In the second kind, Bob (or both Alice and Bob) is allowed to compensate his axis within any direction. The reason why we consider these two kind of compensations in the BB84 protocol is as follows. Since we only use the z-basis and x-basis in the BB84 protocol, it is natural to consider the axis compensation within the z-x plane. On the other hand, we might use the axis compensation within any direction if we are allowed to enhance the device for the compensation. Indeed, several researchers employ the compensation within any direction in the literature [3, 4, 5, 6, 7, 8, 9]. Therefore, we also investigate the compensation within any direction.

The optimized key generation rates (of the standard postprocessing) \( F_1(\mathcal{E}) \), \( \tilde{F}_1(\mathcal{E}) \), \( F_2(\mathcal{E}) \), \( \tilde{F}_2(\mathcal{E}) \), \( G_1(\mathcal{E}) \), \( \tilde{G}_1(\mathcal{E}) \), \( G_2(\mathcal{E}) \), \( \tilde{G}_2(\mathcal{E}) \), \( J_1(\mathcal{E}) \), \( \tilde{J}_1(\mathcal{E}) \), \( J_2(\mathcal{E}) \), \( \tilde{J}_2(\mathcal{E}) \) for above described 12 settings are summarized in Table 1. These quantities are formally defined in Sections 2.2 and 2.3 respectively.

| Channel estimation | Accurate \( F_1(\mathcal{E}) \) | Conventional \( \tilde{F}_1(\mathcal{E}) \) |
|--------------------|-------------------------------|---------------------------------|
| Six-state          | One-side \( F_2(\mathcal{E}) \) | One-side \( \tilde{F}_2(\mathcal{E}) \) |
|                    | Two-side \( F_2(\mathcal{E}) \) | Two-side \( \tilde{F}_2(\mathcal{E}) \) |
| BB84               | One-side \( G_1(\mathcal{E}) \) | One-side \( \tilde{G}_1(\mathcal{E}) \) |
|                    | Two-side \( G_2(\mathcal{E}) \) | Two-side \( \tilde{G}_2(\mathcal{E}) \) |
| Any direction      | One-side \( J_1(\mathcal{E}) \) | One-side \( \tilde{J}_1(\mathcal{E}) \) |
|                    | Two-side \( J_2(\mathcal{E}) \) | Two-side \( \tilde{J}_2(\mathcal{E}) \) |

In this paper, we investigate the above described optimized key generation rates, and derive closed-form expression of \( F_1(\mathcal{E}) \), \( F_2(\mathcal{E}) \), \( G_1(\mathcal{E}) \), \( G_2(\mathcal{E}) \), \( J_1(\mathcal{E}) \), and \( J_2(\mathcal{E}) \) for unital channels. Since QKD protocols can be implemented over many different media, such as an optical fiber, free space, and an unknown medium, we should conduct theoretical research with general quantum channels. In this paper we deal with unital channels because we have closed-form expressions of key generations rates of the QKD protocols. The existence of such closed-form expressions enables us to identify optimal compensation procedures. Without them identification is difficult.

By using the closed-form expressions of the optimized key generation rates, we also derive the following relationships:

\[
F_2(\mathcal{E}) = \tilde{F}_2(\mathcal{E}) = F_1(\mathcal{E}) \geq \tilde{F}_1(\mathcal{E}), \\
G_2(\mathcal{E}) = \tilde{G}_2(\mathcal{E}) = G_1(\mathcal{E}) \geq \tilde{G}_1(\mathcal{E}), \\
J_2(\mathcal{E}) = \tilde{J}_2(\mathcal{E}) \geq J_1(\mathcal{E}) \geq \tilde{J}_1(\mathcal{E})
\]

hold for any unital channel, and

\[
F_1(\mathcal{E}) > \tilde{F}_1(\mathcal{E}), \\
G_1(\mathcal{E}) > \tilde{G}_1(\mathcal{E}), \\
J_1(\mathcal{E}) > \tilde{J}_1(\mathcal{E})
\]
Our results provide the following important insight. In the literatures [3, 4, 5, 6, 7, 8, 9], they employ the one-side compensation for the axis compensation phase and the conventional channel estimation for the channel estimation phase. However, when we employ the one-side compensation, above mentioned relationships imply that we should use the accurate channel estimation. On the other hand, when we employ the two-side compensation, above mentioned relationships imply that we do not have to use the accurate channel estimation.

The rest of this paper is organized as follows: In Section 2, we formally describe the problem mentioned above for the six-state protocol and the BB84 protocol. In Section 3, we provide closed-form expressions of the optimized key generation rates, and also clarify the relationships among the optimized key generation rates for various settings. We state the conclusion in Section 4.

2 Problem Formulation

In this section, we formally describe the problem we investigate in this paper. Suppose that Alice and Bob are connected by a qubit channel $E_B$ from the set of all qubit density operators to themselves. As is usual in QKD literatures, we assume that Eve can access all the environment of channel $E_B$; the channel to the environment is denoted by $E_E$. In the rest of this paper, we omit the subscripts $B$ and $E$ if they are obvious from the context.

It should be noted that $E$ can be any qubit channel throughout the paper, unless we specify the channel to be a Pauli channel or a unital channel.

2.1 Stokes parameterization and Choi Operator

For convenience, we introduce the Stokes parameterization and the Choi operator for the qubit channel. The qubit channel $E$ can be described by the affine map parameterized by 12 real parameters [16, 17] as follows:

$$
\begin{bmatrix}
\theta_z \\
\theta_x \\
\theta_y
\end{bmatrix}
\mapsto
\begin{bmatrix}
R_{zz} & R_{zx} & R_{zy} \\
R_{xz} & R_{xx} & R_{xy} \\
R_{yz} & R_{yx} & R_{yy}
\end{bmatrix}
\begin{bmatrix}
\theta_z \\
\theta_x \\
\theta_y
\end{bmatrix} +
\begin{bmatrix}
t_z \\
t_x \\
t_y
\end{bmatrix},
$$

(1)

where $(\theta_z, \theta_x, \theta_y)$ describes a vector in the Bloch sphere [18]. The pair $(R, t)$ of the matrix and the vector in Eq. (1) is called the Stokes parameterization of the channel $E$. In the rest of this paper, we identify the channel $E$ and its Stokes parameterization, and occasionally write $E = (R, t)$.

For the channel $E$ and each pair of bases $(a, b) \in \{z, x, y\}^2$, define the biases of the outputs as

$$
Q_{a0b} := \langle 0_b | E_B(0_a) \rangle - \langle 1_b | E_B(0_a) \rangle,
Q_{a1b} := \langle 1_b | E_B(1_a) \rangle - \langle 0_b | E_B(1_a) \rangle.
$$

4
where $|0_a\rangle$, $|1_a\rangle$ are eigenstates of the Pauli operator $\sigma_a$ for $a \in \{x, y, z\}$ respectively. Then, a straightforward calculation shows the relations

$$R_{ba} = \frac{1}{2}(Q_{ab0} + Q_{ab1}), \quad t_b = \frac{1}{2}(Q_{ab0} - Q_{ab1}).$$

(2)

A unital channel is a channel that maps the completely mixed state $I/2$ to itself. For a unital channel, the vector part $(t_z, t_x, t_y)$ of the Stokes parameterization is the zero vector. Furthermore, the channel is called a Pauli channel if the matrix part $R$ of the Stokes parameterization is a diagonal matrix in addition to that the vector part is the zero vector.

We can also describe the qubit channel $E$ by the Choi operator

$$\rho_{AB} := (\text{id} \otimes E_B)(|\psi\rangle\langle\psi|),$$

where $|\psi\rangle = \sqrt{\frac{1}{2}}(|00\rangle + |11\rangle)$ is a maximally entangled state. For the unital channel, the Choi operator satisfies $\text{Tr}_A[\rho_{AB}] = I/2$. Furthermore, the channel is a Pauli channel if and only if the Choi operator is a Bell diagonal operator, i.e.,

$$\rho_{AB} = \sum_{a \in \{i, z, x, y\}} q_a |\psi_a\rangle\langle\psi_a|$$

for Bell states $|\psi_a\rangle := (I \otimes \sigma_a)|\psi\rangle$ and the probability distribution $(q_i, q_z, q_x, q_y)$ on $\{i, z, x, y\}$, where $\sigma_i$ is the identity operator. Throughout this paper, we omit the subscript $AB$ if it is obvious from the context.

### 2.2 Six-state protocol

As the preparation phase of the six-state protocol, Alice and Bob conduct the following axis compensation procedure. Alice randomly sends bit 0 or 1 to Bob by modulating it into a transmission basis that is randomly chosen from the z-basis $\{|0_z\rangle, |1_z\rangle\}$, the x-basis $\{|0_x\rangle, |1_x\rangle\}$, or the y-basis $\{|0_y\rangle, |1_y\rangle\}$. Then Bob randomly chooses one of measurement observables $\sigma_x$, $\sigma_y$, and $\sigma_z$, and converts a measurement result +1 or −1 into a bit 0 or 1 respectively. After a sufficient number of transmissions, Alice and Bob publicly announce their transmission bases and measurement observables. They also announce all of their bit sequences for estimating channel $E$. Note that Alice and Bob do not discard mismatched measurement outcomes, which are transmitted and received by different bases, and they also use the mismatched measurement outcomes to estimate the channel. From Eq. (2), we find that Alice and Bob can estimate all parameters $(R, t)$ of the channel in the six-state protocol [19][20]. Note that the use of the mismatched measurement outcomes for channel estimation is also known as the process tomography.

We consider two kinds of compensations:

(i) Only Bob is allowed to compensate his axis, i.e., the channel after the compensation is

$$E'_B = U_B \circ E_B,$$

(3)

where $U_B$ is a unitary channel that represents Bob’s compensation.
(ii) Both Alice and Bob are allowed to compensate their axes, i.e., the channel after the compensation is

$$E'_B = U_B \circ E_B \circ U_A,$$

(4)

where $U_A$ and $U_B$ are unitary channels that represent Alice and Bob’s compensations.

Based on the estimate of the parameters $(R, \tau)$, Bob (or both Alice and Bob) decides $U_B$ (or $U_A$ and $U_B$), and he compensates the channel. The choice of $U_B$ (or $U_A$ and $U_B$) can be decided according to Theorem 2 and Corollary 3 of Section 3.1.

**Remark 1** Throughout this paper, the prime represents that it is after the compensation.

After the compensation procedure, Alice and Bob conduct the above bit transmission and reception procedure again. This time, they only announce a part of their bit sequence for estimating the channel $E'$, and they conduct the postprocessing to generate a secret key from the remaining (unannounced) bit sequences.

Henceforth, we focus on the postprocessing procedure for Alice’s bit sequence $x \in \mathbb{F}_2^n$ that is transmitted in $\sigma_z$-basis and corresponding Bob’s bit sequence $y \in \mathbb{F}_2^n$ that is received in $\sigma_z$ measurement, where $\mathbb{F}_2$ is the finite field of order 2. We employ the standard postprocessing procedure that consists of the information reconciliation procedure and the privacy amplification procedure (e.g. see [11, Section 2]). Note that we do not use the so-called noisy preprocessing [12, 13] nor the postprocessing with two-way classical communication [14, 15].

Let

$$H_{E'}(X|E) := H(\rho'_{XE}) - H(\rho'_E)$$

be the conditional von Neumann entropy with respect to the density operator

$$\rho'_{XE} := \frac{1}{2} |x_z\rangle\langle x_z| \otimes E'_E(|x_z\rangle\langle x_z|)$$

on the joint system $\mathcal{H}_X \otimes \mathcal{H}_E$, where $H(\rho)$ is the von Neumann entropy [18] for a density matrix $\rho$, and we take the base of the logarithm to be 2 throughout the paper. For the compensated channel $E'$, we define the joint probability distribution

$$P'_{XY}(x, y) := \frac{1}{2} |y_z\rangle E'_E(|x_z\rangle\langle x_z|)|y_z\rangle$$

of the joint random variable $(X, Y)$ on $\mathbb{F}_2 \times \mathbb{F}_2$. Then, let

$$H_{E'}(X|Y) := - \sum_{x,y \in \mathbb{F}_2} P'_{XY}(x,y) \log P'_{XY}(x|y)$$

(5)

be the conditional Shannon entropy of $X$ given $Y$. 

6
In the six-state protocol, since Alice and Bob can estimate the channel $E'$ exactly if they use the accurate channel estimation, they can asymptotically share a secure key if the length $\ell$ of the key satisfies

$$\frac{\ell}{n} < H_{E'}(X|E) - H_{E'}(X|Y)$$

(see [21][11]). Therefore, we consider the following two optimization problems:

(i) Find a closed-form expression of

$$F_1(E) := \max_{U_B} [H_{E'}(X|E) - H_{E'}(X|Y)],$$

and also find $U_B$ that achieves the maximum in Eq. (6).

(ii) Find a closed-form expression of

$$F_2(E) := \max_{U_A, U_B} [H_{E'}(X|E) - H_{E'}(X|Y)],$$

and also find $(U_A, U_B)$ that achieve the maximum in Eq. (7).

Eqs. (6) and (7) are the key generation rates optimized within the one-side compensation and the two-side compensation respectively.

Next, we consider the case in which Alice and Bob use the conventional channel estimation (see [11] for the detail of the conventional estimation). From Eq. (2), we find that Alice and Bob can only estimate the parameters $\gamma' = (R'_{zz}, R'_{xx}, R'_{yy})$, and they cannot estimate the parameters $\kappa' = (R'_{zx}, R'_{zy}, R'_{xz}, R'_{yx}, R'_{yz}, R'_{xy}, t'_z, t'_x, t'_y)$. Since we have to consider the worst case with respect to the parameters $\kappa'$ that cannot be estimated, we consider the following two quantities:

$$\tilde{F}_1(E) := \max_{U_B} \min_{E \in P_s(\gamma')} [H_{\tilde{E}}(X|E) - H_{\tilde{E}}(X|Y)],$$

and

$$\tilde{F}_2(E) := \max_{U_A, U_B} \min_{E \in \tilde{P}_s(\gamma')} [H_{\tilde{E}}(X|E) - H_{\tilde{E}}(X|Y)],$$

where $P_s(\gamma')$ is the set of all channel for given $\gamma'$, i.e.,

$$P_s(\gamma') := \{ \tilde{E} = (\tilde{\gamma}, \tilde{k}) : \tilde{\gamma} = \gamma' \}.$$

Since the definition of $\tilde{F}_1(E)$ and $\tilde{F}_2(E)$ involve the minimization, we have $F_1(E) \geq \tilde{F}_1(E)$ and $F_2(E) \geq \tilde{F}_2(E)$ [11].
2.3 BB84 protocol

2.3.1 Compensation within z-x Plane

The BB84 protocol is almost the same as the six-state protocol. However in the BB84 protocol with the axis compensation within the z-x plane, Alice uses only z basis and x basis to transmit the bit sequence, and Bob uses only observable $\sigma_z$ and $\sigma_x$ to receive the bit sequence. Therefore, from Eq. (2), we find that Alice and Bob can only estimate the parameters $\omega = (R_{zz}, R_{zx}, R_{xz}, t_z, t_x)$, and that they cannot estimate the parameters $\tau = (R_{zy}, R_{xy}, R_{yx}, t_y, t_y')$. We consider the following two kinds of compensations:

(i) Only Bob is allowed to compensate his axis within the z-x plane, i.e., the channel after the compensation is given by Eq. (3), where $U_B$ is a unitary channel that rotate the Bloch sphere within the z-x plane.

(ii) Both Alice and Bob are allowed to compensate their axes within the z-x plane, i.e., the channel after the compensation is given by Eq. (4), where $U_A$ and $U_B$ are unitary channels that rotate the Bloch sphere within the z-x plane.

Based on the estimate of the parameters $\omega$, Bob (or both Alice and Bob) decides $U_B$ (or $U_A$ and $U_B$), and he compensates the channel. The choice of $U_B$ (or $U_A$ and $U_B$) can be decided according to Theorem 7 and Corollary 8 of Section 3.2.1.

As in the six-state protocol, we also employ the standard postprocessing. We first consider the case in which Alice and Bob use the accurate channel estimation. Note that Alice and Bob can only estimate the parameters $\omega' = (R_{zz}', R_{zx}', R_{xz}', t_z', t_x')$, and that they cannot estimate the parameters $\tau' = (R_{zy}', R_{xy}', R_{yx}', t_y', t_y')$.

Let $P_{ba}(\omega')$ be the set of all channels for given $\omega'$, i.e.,

$$P_{ba}(\omega') := \{ \tilde{E} = (\tilde{\omega}, \tilde{\tau}) : \tilde{\omega} = \omega' \}.$$

In the BB84 protocol, Alice and Bob can asymptotically share a secure key if the length $\ell$ of the key satisfies

$$\frac{\ell}{n} < \min_{E \in P_{ba}(\omega')} [H_{E}(X|E) - H_{E}(X|Y)]$$

(see [21, 11]). Therefore, we consider the following two optimization problems:

(i) Find a closed-form expression of

$$G_1(\tilde{E}) := \max_{U_B} \min_{E \in P_{ba}(\omega')} [H_{E}(X|E) - H_{E}(X|Y)],$$

and also find $U_B$ that achieves the maximum in Eq. (10), where $U_B$ is a unitary channel that rotates the Bloch sphere within the z-x plane.
(ii) Find a closed-form expression of

$$G_2(E) := \max_{\mathcal{U}_A, \mathcal{U}_B} \min_{\tilde{E} \in \mathcal{P}_{bc}(\mu')} [H_{\tilde{E}}(X|E) - H_{\tilde{E}}(X|Y)],$$

and also find $$(\mathcal{U}_A, \mathcal{U}_B)$$ that achieve the maximum in Eq. (11), where $\mathcal{U}_A$ and $\mathcal{U}_B$ are unitary channels that rotate the Bloch sphere within the $z$–$x$ plane.

Next, we consider the case in which Alice and Bob use the conventional channel estimation. From Eq. (2), we find that Alice and Bob can only estimate the parameters $\mu' = (R'_{zz}, R'_{xx})$, and they cannot estimate the parameters $\nu' = (R'_{xz}, R'_{xy}, R'_{yx}, R'_{yy}, t'_z, t'_x, t'_y)$. Since we have to consider the worst case with respect to the parameters $\nu'$ that cannot be estimated, we consider the following two quantities:

$$\tilde{G}_1(E) := \max_{\mathcal{U}_A} \min_{\tilde{E} \in \mathcal{P}_{bc}(\mu')} [H_{\tilde{E}}(X|E) - H_{\tilde{E}}(X|Y)],$$

and

$$\tilde{G}_2(E) := \max_{\mathcal{U}_A, \mathcal{U}_B} \min_{\tilde{E} \in \mathcal{P}_{bc}(\mu')} [H_{\tilde{E}}(X|E) - H_{\tilde{E}}(X|Y)],$$

where $\mathcal{P}_{bc}(\mu')$ is the set of all channel for given $\mu'$, i.e.,

$$\mathcal{P}_{bc}(\mu') := \{\tilde{E} = (\tilde{\mu}, \tilde{\nu}) : \tilde{\mu} = \mu'\}.$$

Since the range of the minimizations in the definitions of $G_1(E), G_2(E), \tilde{G}_1(E)$, and $\tilde{G}_2(E)$ satisfy $\mathcal{P}_{bc}(\omega') \subset \mathcal{P}_{bc}(\mu')$, we have $G_1(E) \geq \tilde{G}_1(E)$ and $G_2(E) \geq \tilde{G}_2(E)$ [11].

### 2.3.2 Compensation within Any Direction

In this section, we consider the BB84 protocol with the axis compensation within any direction. We consider this problem because several researchers employ the compensation within any direction in the literatures [3, 4, 5, 6, 7, 8, 9].

When we employ the one-side compensation, Alice randomly sends 0 or 1 to Bob by modulating it into a transmission basis that is randomly chosen from the $z$–basis or the $x$–basis. Then Bob measures received qubits by randomly using observables $\sigma_z, \sigma_x$ or $\sigma_y$. Note that Bob can use $\sigma_y$ in addition to $\sigma_z$ and $\sigma_x$ because he is allowed to rotate the axis of the receiver in the axis compensation phase. In this case, from Eq. (2), we find that Alice and Bob can estimate the parameters $(R_{zz}, R_{xz}, R_{yz}, R_{xx}, R_{xy}, R_{yx}, t_z, t_x, t_y)$, and they cannot estimate the parameters $(R_{zy}, R_{xy}, R_{yy})$. Since Bob can use $\sigma_y$, Alice and Bob can estimate $(R_{yz}, R_{yx}, t_y)$ in addition to $(R_{zz}, R_{xz}, R_{xx}, t_z, t_x)$, which can be estimated in the compensation scheme of Section 2.3.1. Based on the estimate of the parameters $(R_{zz}, R_{xz}, R_{yz}, R_{xx}, R_{xy}, t_z, t_x, t_y)$, Bob decide $\mathcal{U}_B$ and compensate the channel. The choice of $\mathcal{U}_B$ can be decided according to Theorem [12] of Section 3.2.2.
On the other hand, when we employ the two-side compensation, we allow both Alice and Bob to use z-basis, x-basis, and y-basis in the axis compensation phase. In this case, from Eq. (2), we find that Alice and Bob can estimate all of the parameters \((R, t)\). Based on the estimate of the parameters \((R, t)\), Alice and Bob decide \(U_A\) and \(U_B\), and they compensate the channel. The choice of \(U_A\) and \(U_B\) can be decided according to Theorem \([11]\) of Section \([3,2,2]\).

In the bit transmission phase (after the axis compensation phase), we allow Alice and Bob to use only z-basis and x-basis. The channel estimation phase and the postprocessing phase are exactly the same as in Section \([2,3,1]\). Note that Alice and Bob can estimate \((R'_{zz}, R'_{xz}, R'_{zx}, R'_{xx}, t'_z, t'_x)\), but they cannot estimate the other parameters, because we do not allow neither Alice nor Bob to use y-basis in the bit transmission phase. Therefore, we consider the following two optimization problems:

(i) Find a closed-form expression of

\[
J_1(\xi) := \max_{U_B} \min_{\tilde{E} \in \mathcal{P}_{ba}(\omega')} \{H_{\tilde{E}}(X|\xi) - H_{\tilde{E}}(X|\tilde{Y})\},
\]

and also find \(U_B\) that achieve the maximum in Eq. (14), where \(U_B\) is any unitary channel.

(ii) Find a closed-form expression of

\[
J_2(\xi) := \max_{U_A, U_B} \min_{\tilde{E} \in \mathcal{P}_{ba}(\omega')} \{H_{\tilde{E}}(X|\xi) - H_{\tilde{E}}(X|\tilde{Y})\},
\]

and also find \((U_A, U_B)\) that achieve the maximum in Eq. (15), where \(U_A\) and \(U_B\) are any unitary channels.

We also treat the case in which Alice and Bob use the conventional channel estimation. In this case, we consider the following two quantities:

\[
\tilde{J}_1(\xi) := \max_{U_B} \min_{\tilde{E} \in \mathcal{P}_{bc}(\mu')} \{H_{\tilde{E}}(X|\xi) - H_{\tilde{E}}(X|\tilde{Y})\},
\]

and

\[
\tilde{J}_2(\xi) := \max_{U_A, U_B} \min_{\tilde{E} \in \mathcal{P}_{bc}(\mu')} \{H_{\tilde{E}}(X|\xi) - H_{\tilde{E}}(X|\tilde{Y})\},
\]

where \(U_A\) and \(U_B\) are any unitary channels. Since the range of the minimizations in the definitions of \(J_1(\xi), J_2(\xi), \tilde{J}_1(\xi), \) and \(\tilde{J}_2(\xi)\) satisfy \(\mathcal{P}_{ba}(\omega') \subset \mathcal{P}_{bc}(\mu')\), we have \(J_1(\xi) \geq \tilde{J}_1(\xi)\) and \(J_2(\xi) \geq \tilde{J}_2(\xi)\) \([11]\).

### 3 Optimal Compensation for Unital Channels

In this section, we solve the problems formulated in Sections \([2,2,2] \([2,3,1]\) and \([2,3,2]\) respectively for unital channels.
3.1 Six-state protocol

For any channel $\mathcal{E} = (R, t)$, by the singular value decomposition, we can decompose the matrix $R$ as

$$R = B \text{ diag}[e_z, e_x, e_y] A$$

where $A$ and $B$ are the rotation matrices $|e_z|$, $|e_x|$, and $|e_y|$ are the singular values of $R$, and we set $⟨\tilde{A}_z⟩ = (e_z A_{zz}, e_x A_{zx}, e_y A_{zy})$, $⟨\tilde{A}_x⟩ = (e_z A_{xz}, e_x A_{xx}, e_y A_{xy})$, and $⟨\tilde{A}_y⟩ = (e_z A_{yz}, e_x A_{yx}, e_y A_{yy})$.

Henceforth, we identify Alice’s compensation $\mathcal{U}_A$ and Bob’s compensation $\mathcal{U}_B$ with the $3 \times 3$ rotation matrices $O_A$ and $O_B$. Then, the matrix part of the Stokes parameterization of the compensated channel $\tilde{\mathcal{E}}' = (R', t')$ is given by $R' = O_B R O_A$.

The following theorem gives a closed-form expression of the key generation rate optimized by the two-side compensation.

**Theorem 2** Suppose that $\mathcal{E}$ is a unital channel. Let $O_A^* = A^{-1}$ and $O_B^* = B^{-1}$, and let $\mathcal{U}_A^*$ and $\mathcal{U}_B^*$ be the unitary channels corresponding to $O_A^*$ and $O_B^*$ respectively. Then, the compensated channel $\tilde{\mathcal{E}}^* = \mathcal{U}_B^* \circ \mathcal{E} \circ \mathcal{U}_A^*$ is the Pauli channel such that the matrix part of the Stokes parameterization is given by $R^* = \text{ diag}[e_z, e_x, e_y]$, and $\tilde{\mathcal{E}}^*$ satisfies

$$F_2(\tilde{\mathcal{E}}) = \max_{\mathcal{U}_A, \mathcal{U}_B} [H_{\tilde{\mathcal{E}}'}(X|E) - H_{\tilde{\mathcal{E}}'}(X|Y)]$$

$$= H_{\tilde{\mathcal{E}}'}(X|E) - H_{\tilde{\mathcal{E}}'}(X|Y)$$

$$= 1 - H[q_1, q_2, q_x, q_y],$$

where $H[q_1, q_2, q_x, q_y]$ is the Shannon entropy of the distribution

$$q_1 = \frac{1 + e_z + e_x + e_y}{4},$$

$$q_2 = \frac{1 + e_z - e_x - e_y}{4},$$

$$q_x = \frac{1 - e_z + e_x - e_y}{4},$$

$$q_y = \frac{1 - e_z - e_x + e_y}{4}.$$
Furthermore, the maximum in Eq. (19) is achieved without any compensation, i.e.,
\[ H_{E}(X|E) - H_{E}(X|Y) = H_{E'}(X|E) - H_{E'}(X|Y) \]
if and only if the vectors $|\tilde{A}_{z}\rangle$ and $|B_{z}\rangle$ are scalar multiple of each other.

The first statement implies that an optimal compensation procedure is to compensate the channel to a Pauli channel. The second statement implies that $(U_{A}, U_{B})$ achieving the maximum are not unique.

The following corollary gives a closed-form expression of the key generation rate optimized by the one-side compensation.

**Corollary 3** Suppose that $E$ is a unital channel. Let
\[
O_{B}^{*} = \begin{bmatrix} \langle O_{B,x}^{*} \rangle \\ \langle O_{B,y}^{*} \rangle \end{bmatrix}
\]
be a rotation matrix such that $\langle O_{B,x}^{*} \rangle$ is a scalar multiple of $(R_{zz}, R_{xz}, R_{yz})$, where $\langle O_{B,x}^{*} \rangle$ and $\langle O_{B,y}^{*} \rangle$ can be arbitrary as long as they constitute a rotation matrix, and let $U_{B}^{*}$ the unitary channel corresponding to $O_{B}^{*}$. Then, the compensated channel $E^{*} = U_{B}^{*} \circ E$ satisfies
\[
F_{1}(E) = H_{E'}(X|E) - H_{E'}(X|Y) = F_{2}(E).
\]

Note that Corollary 3 follows from the second statement of Theorem 2.

Surprisingly, we do not lose any optimality even if we only allow Bob to compensate his axis (one-side compensation). This fact is useful to simplify the implementation of the optimal compensation procedure.

Since $H_{E}(X|Y) = h((1 + R_{zz})/2)$ for any unital channel and $R_{zz} = \langle B_{z}|\tilde{A}_{z}\rangle$, we find that an optimal one-side compensation procedure is to compensate the channel so that Bob can detect Alice’s transmitted state most reliably, i.e., $H_{E'}(X|Y)$ is minimized, where $h(\cdot)$ is the binary entropy function. Note that the fact that $|\tilde{A}_{z}\rangle$ and $|B_{z}'\rangle$ is scalar multiple of each other does not necessarily mean the compensated channel $E'$ is a Pauli channel.

**Proof of Theorem 2**. The equality between Eqs. (20) and (21) is well known (e.g. see [12] or [11, Eq. (20)]). Since Eq. (19) is obviously larger than or equals to Eq. (20), it suffices to show that Eq. (19) is smaller than or equals to Eq. (21) for any $U_{A}$ and $U_{B}$. For any fixed $U_{A}$ and $U_{B}$, by using [11, Eq. (20)] and the discussions right before it, Eq. (19) can be rewritten as
\[
1 - H[q_{i}, q_{z}, q_{x}, q_{y}] + h\left(\frac{1 + ||\tilde{A}_{z}'||}{2}\right) - h\left(\frac{1 + \langle B_{z}'|\tilde{A}_{z}\rangle}{2}\right).
\]
From the form of $h(\cdot)$, Cauchy’s inequality $|\langle B'_z| \tilde{A}'_z \rangle| \leq \| \tilde{A}'_z \|$ implies that Eq. (19) is smaller than or equals to Eq. (21). The equality holds if and only if the vectors $|\tilde{A}'_z \rangle$ and $|B'_z \rangle$ are scalar multiple of each other, which is exactly the second statement of the theorem.

Next, we consider the case in which Alice and Bob use the conventional channel estimation. The following theorem states that the optimized key generation rate with the accurate channel estimation coincides with that with the conventional channel estimation if we use the two-side compensation. The following theorem also gives the necessary and sufficient condition such that the optimized key generation rates with the accurate channel estimation and the conventional channel estimation coincide when we use the one-side compensation.

**Theorem 4** Suppose that $\mathcal{E}$ is a unital channel. Then, we have

$$F_2(\mathcal{E}) = \tilde{F}_2(\mathcal{E}),$$

where $\tilde{F}_2(\mathcal{E})$ is achieved by $O_A^*$ and $O_B^*$ specified in Theorem 2. Furthermore, we have

$$F_1(\mathcal{E}) = \tilde{F}_1(\mathcal{E})$$

if and only if $|\tilde{A}_z \rangle$, $|\tilde{A}_x \rangle$, and $|\tilde{A}_y \rangle$ are orthogonal to each other. If this condition is satisfied, then $\tilde{F}_1(\mathcal{E})$ is achieved by $O_B^*$ such that $\langle O_B^* \rangle$ and $\langle O_B^* \rangle$ are scalar multiple of $(R_{zz}, R_{sx}, R_{yz}), (R_{zx}, R_{sx}, R_{yx})$, and $(R_{zy}, R_{sy}, R_{yy})$ respectively.

**Corollary 5** Suppose that $\mathcal{E}$ is a unital channel. Then, we have

$$\tilde{F}_1(\mathcal{E}) = \tilde{F}_2(\mathcal{E})$$

if and only if $|\tilde{A}_z \rangle$, $|\tilde{A}_x \rangle$, and $|\tilde{A}_y \rangle$ are orthogonal to each other. □

**Proof of Theorem 4** Let $\mathcal{E}^*$ be the Pauli channel defined in Theorem 2. Then, we have

$$F_2(\mathcal{E}) \geq \tilde{F}_2(\mathcal{E})$$

which implies the first statement of the theorem.

To prove the “if” part of the second statement, assume that $|\tilde{A}_z \rangle$, $|\tilde{A}_x \rangle$, and $|\tilde{A}_y \rangle$ are orthogonal to each other. Then, we can take a rotation matrix $O_B^*$ so that $\langle O_B^* \rangle$ and $\langle O_B^* \rangle$ are scalar multiple of $(R_{zz}, R_{sx}, R_{yz}), (R_{zx}, R_{sx}, R_{yx})$, and $(R_{zy}, R_{sy}, R_{yy})$ respectively, and we have $R^* = O_B^* R = \text{diag}[e_z, e_x, e_y]$. Thus, we have

$$F_1(\mathcal{E}) \geq \tilde{F}_1(\mathcal{E}) \geq 1 - H[q_i, q_z, q_x, q_y] = F_1(\mathcal{E}).$$
Next, we show the “only if” part of the second statement. Suppose that at least one pair of $|\tilde{A}_z\rangle$, $|\tilde{A}_x\rangle$, and $|\tilde{A}_y\rangle$ is not orthogonal to each other. Then, for arbitrarily fixed $\mathcal{U}_B$, the compensated channel $E'$ is not a Pauli channel, i.e., the Choi operator $\rho'$ is not a Bell diagonal state. Let $\rho_a' := (\sigma_a \otimes \sigma_a)^{r'}(\sigma_a \otimes \sigma_a)$ for $a \in \{i, z, x, y\}$, where $\sigma_a$ is the complex conjugate of $\sigma_a$. Since $\rho'$ is not Bell diagonal state, at least one of $\rho_z'$, $\rho_x'$, and $\rho_y'$ is different from $\rho_i'$. Let $\rho_{tw} := \sum_{a \in \{i, z, x, y\}} \frac{1}{4} \rho_a'$ be the partially twirled state [23]. Then, since the von Neumann entropy is a strict concave function [18], we have

$$F_1(E) = \max_{\mathcal{U}_B} [1 - H(\rho_{tw}')] < \max_{\mathcal{U}_B} [1 - \sum_{a \in \{i, z, x, y\}} \frac{1}{4} H(\rho_a')] = \max_{\mathcal{U}_B} [1 - H(\rho')] = F_1(E).$$

$\Box$

3.2.1 Compensation within z-x Plane

For any channel $E = (R, t)$, by the singular value decomposition, we can decompose the left upper $2 \times 2$ sub-matrix $S$ of the matrix $R$ as

$$S = V \text{diag}[d_z, d_x] U = \begin{bmatrix} \langle V_z | & d_z & 0 & |U_z\rangle \\ \langle V_x | & 0 & d_x & |U_x\rangle \end{bmatrix} = \begin{bmatrix} \langle V_z |\tilde{U}_z\rangle & \langle V_z |\tilde{U}_x\rangle \\ \langle V_x |\tilde{U}_z\rangle & \langle V_x |\tilde{U}_x\rangle \end{bmatrix},$$

where $U$ and $V$ are the rotation matrices, $|d_z|$ and $|d_x|$ are the singular values of $S$, and we set $\langle \tilde{U}_z \rangle = (d_z U_{zz}, d_x U_{zx})$ and $\langle \tilde{U}_x \rangle = (d_z U_{xz}, d_x U_{xx})$.

Henceforth, we identify Alice’s compensation $\mathcal{U}_A$ and Bob’s compensation $\mathcal{U}_B$ with the $2 \times 2$ rotation matrices $Q_A$ and $Q_B$, because their compensation are restricted within the z-x plane. Note that the left upper $2 \times 2$ sub-matrix $S'$ of the matrix $R'$ of the compensated channel is given by $S' = Q_B S Q_A$.

The following lemma provides a closed-form expression of the key generation rate with the accurate channel estimation for unital channels, and it will be used several times in the rest of this paper.
Lemma 6 For any unital channel $E = (\omega, \tau)$, we have

$$\min_{\tilde{E} \in P_{ba}(\omega)} [H_{\tilde{E}}(X|E) - H_{\tilde{E}}(X|Y)] = 1 - h \left( \frac{1 + dz}{2} \right) - h \left( \frac{1 + dx}{2} \right) + h \left( \frac{1 + R_{zz}}{2} + R_{xz}^2 \right) - h \left( \frac{1 + R_{zz}}{2} \right).$$

Proof of Lemma 6 This lemma follows from [11, Proposition 2] and the fact $H_{\tilde{E}}(X|Y) = h((1 + R_{zz})/2)$ for any unital channel. □

The following theorem gives a closed-form expression of the key generation rate optimized by the two-side compensation.

Theorem 7 Suppose that $E$ is a unital channel. Let $Q_A^* = U^{-1}$ and $Q_B^* = V^{-1}$, and let $\mathcal{U}_A^*$ and $\mathcal{U}_B^*$ be the unitary channels corresponding to $Q_A^*$ and $Q_B^*$ respectively. Then, the compensated channel $\mathcal{U}_B^* \circ E \circ \mathcal{U}_A^* = (\omega^*, \tau^*)$ satisfies

$$G_2(E) = \max_{\mathcal{U}_A^*, \mathcal{U}_B^*} \min_{E \in P_{ba}(\omega^*)} [H_{\tilde{E}}(X|E) - H_{\tilde{E}}(X|Y)]$$

if and only if the vectors $|\tilde{U}_z\rangle$ and $|V_z\rangle$ are scalar multiple of each other.

The first statement implies that an optimal compensation procedure is to compensate the channel to a channel such that the left upper sub-matrix $S'$ of the Stokes parameterization of the compensated channel is a diagonal matrix. The latter statement implies that $(\mathcal{U}_A^*, \mathcal{U}_B^*)$ achieving the maximum is not unique.

By using Theorem 7 we can derive the following corollary, which gives the key generation rate optimized by the one-side compensation.

Corollary 8 Suppose that $E$ is a unital channel. Let

$$Q_B^* = \begin{bmatrix} \langle Q_{B,z}^* \rangle \\ \langle Q_{B,x}^* \rangle \end{bmatrix}$$

be a rotation matrix such that $\langle Q_{B,z}^* \rangle$ is a scalar multiple of $(R_{zz}, R_{xz})$ and let $\mathcal{U}_B^*$ be the unitary channel corresponding to $Q_B^*$. Then, the compensated channel

Note that $\langle Q_{B,z} \rangle$ is uniquely determined from $\langle Q_{B,z} \rangle$ because they constitute a rotation matrix.
$U_B \circ \mathcal{E} =: \mathcal{E}' = (\omega', \tau')$ satisfies

\[
G_1(\mathcal{E}) = \min_{\mathcal{E} \in \mathcal{P}_{ba}(\omega')} [H_{\tilde{E}}(X|E) - H_{\tilde{E}}(X|Y)] \quad \text{(29)}
\]

\[
= G_2(\mathcal{E}). \quad \text{(30)}
\]

Note that Corollary 8 follows from the latter statement of Theorem 7.

Surprisingly, we do not lose any optimality even if we only allow Bob to compensate his axis (one-side compensation). This fact is useful to simplify the implementation of the optimal compensation procedure.

Since $H_{\tilde{E}}(X|Y) = h((1 + R_{zz})/2)$ for any unital channel and $R_{zz} = \langle V_z'|\tilde{U}_z' \rangle$, we find that an optimal one-side compensation procedure is to compensate the channel so that Bob can detect Alice’s transmitted state most reliably, i.e., $H_{\tilde{E}}(X|Y)$ is minimized. Note that the fact that $|\tilde{U}_z\rangle$ and $|V_z'\rangle$ is scalar multiple of each other does not necessarily mean that the left upper sub-matrix $S'$ of the Stokes parameterization of the compensated channel is a diagonal matrix.

Proof of Theorem 7) By using Lemma 6, we have the equality between Eqs. (27) and (28). Since Eq. (26) is obviously larger than or equals to Eq. (27), it suffices to show that Eq. (26) is smaller than or equals to Eq. (28). For any fixed $U_A$ and $U_B$, by using Lemma 6 again, Eq. (26) can be rewritten as

\[
1 - h\left(\frac{1 + d_z}{2}\right) - h\left(\frac{1 + d_x}{2}\right) + h\left(\frac{1 + ||\tilde{U}_z'||}{2}\right) - h\left(\frac{1 + \langle V_z'|\tilde{U}_z' \rangle}{2}\right).
\]

From the form of $h(\cdot)$, Cauchy’s inequality $|\langle V_z'|\tilde{U}_z' \rangle| \leq ||\tilde{U}_z'||$ implies that Eq. (26) is smaller than or equals to Eq. (28). The equality holds if and only if the vectors $|\tilde{U}_z'\rangle$ and $|V_z'\rangle$ are scalar multiple of each other, which is exactly the second statement of the theorem.

Next, we consider the case in which Alice and Bob use the conventional channel estimation. The following theorem states that the optimized key generation rate with the accurate channel estimation coincides with that with the conventional channel estimation if we use the two-side compensation. The following theorem also gives the necessary and sufficient condition such that the optimized key generation rates with the accurate channel estimation and the conventional channel estimation coincide when we use the one-side compensation.

Theorem 9 Suppose that $\mathcal{E}$ is a unital channel. Then, we have

\[
G_2(\mathcal{E}) = \tilde{G}_2(\mathcal{E}),
\]

where $\tilde{G}_2(\mathcal{E})$ is achieved by $Q_A^*$ and $Q_B^*$ specified in Theorem 7. Furthermore, we have

\[
G_1(\mathcal{E}) = \tilde{G}_1(\mathcal{E})
\]
if and only if $|\tilde{U}_z\rangle$ and $|\tilde{U}_x\rangle$ are orthogonal to each other. If this condition is satisfied, $\tilde{G}_1(\mathcal{E})$ is achieved by $Q_\ast^\dagger$ such that $\langle Q_\ast^\dagger, z \rangle$ and $\langle Q_\ast^\dagger, x \rangle$ are scalar multiple of $(R_{zz}, R_{zx})$ and $(R_{zx}, R_{xx})$ respectively.

**Corollary 10** Suppose that $\mathcal{E}$ is a unital channel. Then, we have

$$\tilde{G}_1(\mathcal{E}) = \tilde{G}_2(\mathcal{E})$$

if and only if $|\tilde{U}_z\rangle$ and $|\tilde{U}_x\rangle$ are orthogonal to each other. $\square$

**Proof of Theorem 9** Let $\mathcal{E}^\ast$ be the channel defined in Theorem 7. Then, we have

$$G_2(\mathcal{E}) \geq \tilde{G}_2(\mathcal{E}) \geq \min_{\mathcal{E} \in \mathcal{P}_{bc}(\mu')} [H_{\mathcal{E}}(X|E) - H_{\mathcal{E}}(X|Y)]$$

$$= 1 - h\left(\frac{1 + d_z}{2}\right) - h\left(\frac{1 + d_x}{2}\right) = G_2(\mathcal{E}),$$

which implies the first statement of the theorem.

To prove the “if” part of the second statement, assume that $|\tilde{U}_z\rangle$ and $|\tilde{U}_x\rangle$ are orthogonal to each other. Then, we can take a rotation matrix $Q_\ast^\dagger$ so that $\langle Q_\ast^\dagger, z \rangle$ and $\langle Q_\ast^\dagger, x \rangle$ are scalar multiple of $(R_{zz}, R_{zx})$ and $(R_{zx}, R_{xx})$ respectively, and we have $S' = Q_\ast^\dagger S = \text{diag}[d_z, d_x]$. Then, we have

$$G_1(\mathcal{E}) = \tilde{G}_1(\mathcal{E}) \geq 1 - h\left(\frac{1 + d_z}{2}\right) - h\left(\frac{1 + d_x}{2}\right) = G_1(\mathcal{E}).$$

Next, we show the “only if” part. Suppose that $|\tilde{U}_z\rangle$ and $|\tilde{U}_x\rangle$ are not orthogonal to each other. Then, for an arbitrarily fixed $\mathcal{U}_B$, either $\langle V_z'|\tilde{U}_x \rangle \neq 0$ or $\langle V_x'|\tilde{U}_z \rangle \neq 0$.
holds. Then, we have

\[
\tilde{G}_1(E) = 1 - h\left(\frac{1 + \langle V_z|\tilde{U}_z\rangle}{2}\right) - h\left(\frac{1 + \langle V_x|\tilde{U}_x\rangle}{2}\right)
\]

\[
< 1 - h\left(\frac{1 + \|\tilde{U}_z\|}{2}\right) - h\left(\frac{1 + \|\tilde{U}_x\|}{2}\right)
\]

\[
= 1 - h\left(\frac{1 + \sqrt{d_z^2 U_{zz}^2 + d_x^2 U_{zx}^2}}{2}\right) - h\left(\frac{1 + \sqrt{d_x^2 U_{zx}^2 + d_x^2 U_{xx}^2}}{2}\right)
\]

\[
\leq 1 - U_{zz}^2 h\left(\frac{1 + \sqrt{d_z^2}}{2}\right) - U_{zx}^2 h\left(\frac{1 + \sqrt{d_x^2}}{2}\right)
\]

\[
- U_{xz}^2 h\left(\frac{1 + \sqrt{d_z^2}}{2}\right) - U_{xx}^2 h\left(\frac{1 + \sqrt{d_x^2}}{2}\right)
\]

\[
= 1 - (U_{zz}^2 + U_{zx}^2) h\left(\frac{1 + d_z}{2}\right) - (U_{zx}^2 + U_{xx}^2) h\left(\frac{1 + d_x}{2}\right)
\]

\[
= 1 - h\left(\frac{1 + d_z}{2}\right) - h\left(\frac{1 + d_x}{2}\right)
\]

\[
= G_1(E),
\]

where we used the concavity of the function

\[
h\left(\frac{1 + \sqrt{x}}{2}\right)
\]

in the inequality of Eq. (31). We can show the concavity of Eq. (32) by showing that the second derivative is non-positive. □

### 3.2.2 Compensation within Any Direction

In this section, we consider the case in which either Alice or Bob are allowed to compensate their axes within any direction \([3, 4, 5, 6, 7, 8, 9]\). For any channel \(E = (R, t)\), by the singular value decomposition, we can decompose the matrix \(R\) as in Eq. (18). Furthermore, we identify Alice’s compensation \(\mathcal{U}_A\) and Bob’s compensation \(\mathcal{U}_B\) with the \(3 \times 3\) rotation matrices \(O_A\) and \(O_B\) as in Section 3.1. When we consider the compensation within any direction, it should be noted that we can estimate all the parameters in the two-side compensation and only a part of the parameters in the one-side compensation (see also Section 2.3.2).

The following theorem gives the key generation rate optimized by the two-side compensation.
Theorem 11 Suppose that $\mathcal{E}$ is a unital channel. Let $\mathcal{U}_A^*$ and $\mathcal{U}_B^*$ be unitary channels such that the compensated channel $\mathcal{U}_B^* \circ \mathcal{E} \circ \mathcal{U}_A^* = (\omega^*, \tau^*)$ is a Pauli channel and the singular values $|e_z^*|$, $|e_x^*|$, and $|e_y^*|$ of $R^* = \text{diag}[e_z^*, e_x^*, e_y^*]$ satisfy

$$|e_z^*| \geq |e_x^*| \geq |e_y^*|.$$ 

Then, we have

$$J_2(\mathcal{E}) = \max_{U_i, U_B} \min_{\tilde{E} \in \mathcal{P}_{ba}(\omega^*)} [H_{\tilde{E}}(X|E) - H_{\tilde{E}}(X|Y)] \leq G_2(\mathcal{E}')$$

where $|d_z'|$ and $|d_x'|$ are the singular values of the left upper $2 \times 2$ sub-matrices $S'$ of $R'$ of the compensated channel $\mathcal{E}'$.

Note that the singular values of $R'$ are equal to those of $R^*$. By using the interlacing inequalities for singular values of sub-matrices, we have

$$|e_z^*| \geq \max[|d_z'|, |d_x'|]$$

and

$$|e_x^*| \geq \min[|d_z'|, |d_x'|].$$

These inequalities imply that Eq. 36 is smaller than or equals to Eq. 35, which completes the proof.

The following theorem gives the key generation rate optimized by the one-side compensation.

Theorem 12 Suppose $\mathcal{E}$ be a unital channel. Let

$$O_B' = \begin{pmatrix} \langle O_{B,z}' \rangle \\ \langle O_{B,x}' \rangle \\ \langle O_{B,y}' \rangle \end{pmatrix}$$
be a rotation matrix such that \( \langle O_{Bz}^* \rangle \) and \( \langle O_{Bx}^* \rangle \) span the same subspace as that spanned by \((R_{zz}, R_{xz}, R_{yz})\) and \((R_{xx}, R_{xx}, R_{yx})\), and that \( \langle O_{Bz}^* \rangle \) is a scalar multiple of \((R_{zz}, R_{xz}, R_{yz})\) and let \( \mathcal{U}_B^* \) be the unitary channel corresponding to \( O_B^* \). Then, the compensated channel \( \mathcal{U}_B^* \circ \mathcal{E} = \mathcal{E}^* \) satisfies

\[
\begin{align*}
J_1(\mathcal{E}) & = \max_{\mathcal{U}_B} \min_{\tilde{\mathcal{E}} \in \mathcal{P}_{ba}(\omega^*)} [H_{\tilde{\mathcal{E}}}(X|E) - H_{\tilde{\mathcal{E}}}(X|Y)] \\
& = \min_{\tilde{\mathcal{E}} \in \mathcal{P}_{ba}(\omega^*)} [H_{\tilde{\mathcal{E}}}(X|E) - H_{\tilde{\mathcal{E}}}(X|Y)] \quad (37) \\
& = 1 - h \left( \frac{1 + s_1^*}{2} \right) - h \left( \frac{1 + s_2^*}{2} \right), \quad (38)
\end{align*}
\]

where \( s_1^* \) and \( s_2^* \) are the singular values of the upper left \(2 \times 2\) sub-matrix matrix

\[
S^* = \begin{bmatrix} \langle B_z^* | \tilde{A}_z \rangle & \langle B_z^* | \tilde{A}_x \rangle \\ \langle B_z^* | \tilde{A}_x \rangle & \langle B_z^* | \tilde{A}_x \rangle \end{bmatrix}
\]

of \( R^* = O_B^* R \) such that \( s_1^* \geq s_2^* \).

**Proof of Theorem 12** The second statement of Theorem 7 implies that the equality between Eqs. (38) and (39). Since Eq. (37) is obviously larger than or equals to Eq. (38), we show that Eq. (37) is smaller than or equals to Eq. (39).

For arbitrarily fixed \( O_B \), let \( s_1' \) and \( s_2' \) be the singular values of the upper left \(2 \times 2\) matrix

\[
S' = \begin{bmatrix} \langle B_z' | \tilde{A}_z \rangle & \langle B_z' | \tilde{A}_x \rangle \\ \langle B_z' | \tilde{A}_x \rangle & \langle B_z' | \tilde{A}_x \rangle \end{bmatrix}
\]

of \( R' = O_B R \) such that \( s_1' \geq s_2' \). Then, by using Corollary 8 we have

\[
\begin{align*}
\min_{\tilde{\mathcal{E}} \in \mathcal{P}_{ba}(\omega^*)} [H_{\tilde{\mathcal{E}}}(X|E) - H_{\tilde{\mathcal{E}}}(X|Y)] \\
\leq G_1(E') \\
= 1 - h \left( \frac{1 + s_1'}{2} \right) - h \left( \frac{1 + s_2'}{2} \right). \quad (40)
\end{align*}
\]

By using the minimax principle for singular values [25 Problem 3.6.1], we

---

Note that \( \langle O_{Bz} \rangle \) is uniquely determined from \( \langle O_{Bz} \rangle \) and \( \langle O_{Bx} \rangle \) because they constitute a rotation matrix.
have

\[ s'_1 = \max_{x \in \mathbb{R}^2 : \|x\| = 1} \|S'x\| \]

\[ = \max_{\alpha, \beta \in \mathbb{R}^2 : \|\alpha\| = 1, \|\beta\| = 1} \left\| \begin{bmatrix} \langle B'_z | \tilde{A}_z \rangle & \langle B'_x | \tilde{A}_x \rangle \end{bmatrix} \right\| \left\| \begin{bmatrix} \alpha \\ \beta \end{bmatrix} \right\| \]

\[ = \max_{\alpha, \beta \in \mathbb{R}^2 : \|\alpha\| = 1, \|\beta\| = 1} \left\| \begin{bmatrix} \langle B'_z | (\alpha | \tilde{A}_z \rangle + \beta | \tilde{A}_x \rangle) \rangle & \langle B'_x | (\alpha | \tilde{A}_z \rangle + \beta | \tilde{A}_x \rangle \rangle \end{bmatrix} \right\| \]

\[ = \max_{\alpha, \beta \in \mathbb{R}^2 : \|\alpha\| = 1, \|\beta\| = 1} \sqrt{\langle B'_z | \Gamma_{\alpha, \beta} \rangle^2 + \langle B'_x | \Gamma_{\alpha, \beta} \rangle^2} \]

\[ \leq \max_{\alpha, \beta \in \mathbb{R}^2 : \|\alpha\| = 1, \|\beta\| = 1} \sqrt{\langle B'_z | \Gamma_{\alpha, \beta} \rangle^2 + \langle B'_x | \Gamma_{\alpha, \beta} \rangle^2} \]

\[ = s^*_1, \tag{42} \]

where we set \( |\Gamma_{\alpha, \beta} \rangle := |\alpha \tilde{A}_z \rangle + |\beta \tilde{A}_x \rangle \), and the equality in Eq. (41) holds if \( |B'_z \rangle \rangle \) and \( |B'_x \rangle \rangle \) span the same subspace as that spanned by \( |\tilde{A}_z \rangle \rangle \) and \( |\tilde{A}_x \rangle \rangle \). By using the minimax principle for singular values in a similar manner, we also have

\[ s'_2 = \min_{x \in \mathbb{R}^2 : \|x\| = 1} \|S'x\| \leq s^*_2. \tag{43} \]

Combining Eqs. (40), (42), and (43), we have shown that Eq. (37) is smaller than or equals to Eq. (39). \( \square \)

**Remark 13** The equality

\[ J_1(\mathcal{E}) = J_2(\mathcal{E}) \]

does not hold in general. For example, \( J_1(\mathcal{E}) \neq J_2(\mathcal{E}) \) if \( R = \text{diag}[e_z, e_x, e_y] \) and \( |e_z| < |e_x| < |e_y| \).

Next, we consider the case in which Alice and Bob use the conventional channel estimation. The following theorem states that the optimized key generation rate with the accurate channel estimation coincides with that with the conventional channel estimation if we use the two-side compensation. The following theorem also gives the necessary and sufficient condition such that the optimized key generation rates with the accurate channel estimation and the conventional channel estimation coincide.

**Theorem 14** Suppose that \( \mathcal{E} \) is a unital channel. Then, we have

\[ J_2(\mathcal{E}) = \tilde{J}_2(\mathcal{E}), \]

where \( \tilde{J}_2(\mathcal{E}) \) is achieved by \( O^*_A \) and \( O^*_B \) specified in Theorem 11. Furthermore, we have

\[ J_1(\mathcal{E}) = \tilde{J}_1(\mathcal{E}) \]

21
if and only if $|\tilde{A}_z\rangle$ and $|\tilde{A}_x\rangle$ are orthogonal to each other. If this condition is satisfied, then $\tilde{J}_1(E)$ is achieved by $O^*_{B}$ such that $\langle O^*_{B,z}\rangle$ and $\langle O^*_Bx\rangle$ are scalar multiple of $(R_{zz}, R_{zx}, R_{yz})$ and $(R_{zx}, R_{xx}, R_{yx})$ respectively.

**Corollary 15** Suppose that $E$ is a unital channel. Then, we have

$$\tilde{J}_1(E) < \tilde{J}_2(E)$$

if $|\tilde{A}_z\rangle$ and $|\tilde{A}_x\rangle$ are not orthogonal to each other. □

**Proof of Theorem 14** This theorem can be proved almost in a similar manner to Theorem 9. Therefore, we omit the proof. □

### 4 Conclusion

In this paper, we investigated the axis compensation in the QKD protocols in various settings. We clarified optimal compensation procedures over unital channels for one-side compensation with the accurate channel estimation and for two-side compensation with both estimation, while we could not identify an optimal compensation procedure for one-side compensation with the conventional channel estimation. Although our proposed compensation procedures are optimal for unital channels, it is not clear whether those compensation procedures are optimal or not for general channels. We also clarified that the optimized key generation rates with the conventional channel estimation are strictly smaller than the optimized key generation rates with the accurate channel estimation for the one-side compensation. Our results imply that we should use the accurate channel estimation when we employ the one-side compensation. On the other hand, we do not have to use the accurate channel estimation when we employ the two-side compensation.

Although we clarified the optimal compensation procedures for the standard postprocessing, it is an important future research agenda to clarify the optimal compensation procedures when we employ more complicated postprocessing (e.g. the postprocessing with the noisy preprocessing [12, 13] or the two-way classical communication [14, 15]).

### Acknowledgment

The authors would like to thank Dr. Toyohiro Tsurumaru for bringing the axis compensation problem to our attention. The first author would like to thank Prof. Yasutada Oohama for his support. This research is partly supported by the Japan Society of Promotion of Science under Grants-in-Aid No. 00197137.
