Abstract. We study the relation between quark confinement and chiral symmetry breaking in QCD. Using lattice QCD formalism, we analytically express the various “confinement indicators”, such as the Polyakov loop, its fluctuations, the Wilson loop, the inter-quark potential and the string tension, in terms of the Dirac eigenmodes. In the Dirac spectral representation, there appears a power of the Dirac eigenvalue $\lambda_n$ such as $\lambda_n^{N_1-1}$, which behaves as a reduction factor for small $\lambda_n$. Consequently, since this reduction factor cannot be cancelled, the low-lying Dirac eigenmodes give negligibly small contribution to the confinement quantities, while they are essential for chiral symmetry breaking. These relations indicate no direct, one-to-one correspondence between confinement and chiral symmetry breaking in QCD. In other words, there is some independence of quark confinement from chiral symmetry breaking, which can generally lead to different transition temperatures/densities for deconfinement and chiral restoration. We also investigate the Polyakov loop in terms of the eigenmodes of the Wilson, the clover and the domain-wall fermion kernels, respectively, and find the similar results. The independence of quark confinement from chiral symmetry breaking seems to be natural, because confinement is realized independently of quark masses and heavy quarks are also confined even without the chiral symmetry.

1. Introduction

About 50 years ago, Nambu first proposed an SU(3) gauge theory (QCD) and introduced the SU(3) gauge field (gluons) for the strong interaction [1], just after the introduction of new degrees of freedom of “color” in 1965 [2]. Since the field-theoretical proof on the asymptotic freedom of QCD in 1973 [3, 4], QCD has been established as the fundamental theory of the strong interaction. In particular, perturbative QCD is quite successful for
the description of high-energy hadron reactions in the framework of the parton model [5, 6, 7].

In the low-energy region, however, QCD is a fairly difficult theory because of its strong-coupling nature, and shows nonperturbative properties such as color confinement and spontaneous chiral-symmetry breaking [8, 9]. Here, spontaneous symmetry breaking appears in various physical phenomena, whereas the confinement is highly nontrivial and is never observed in most fields of physics.

For such nonperturbative phenomena, lattice QCD formalism was developed as a robust approach based on QCD [10, 11], and M. Creutz first performed lattice QCD Monte Carlo calculations around 1980 [12]. Owing to lots of lattice QCD studies [13] so far, many nonperturbative aspects of QCD have been clarified to some extent. Nevertheless, most of nonperturbative QCD is not well understood still now.

In particular, the relation between quark confinement and spontaneous chiral-symmetry breaking is not clear, and this issue has been an important difficult problem in QCD for a long time. A strong correlation between confinement and chiral symmetry breaking has been suggested by approximate coincidence between deconfinement and chiral-restoration temperatures [13, 14], although it is not clear whether this coincidence is quantitatively precise or not. At the physical point of the quark masses $m_{u,d}$ and $m_s$, a lattice QCD work [15] shows about 25MeV difference between deconfinement and chiral-restoration temperatures, i.e., $T_{\text{deconf}} \simeq 176\text{MeV}$ and $T_{\text{chiral}} \simeq 151\text{MeV}$, whereas a recent lattice QCD study [16] shows almost the same transition temperatures of $T_{\text{deconf}} \simeq T_{\text{chiral}}$, after solving the scheme dependence of the Polyakov loop.

The correlation of quark confinement with chiral symmetry breaking is also suggested in terms of QCD-monopoles [17, 18, 19], which topologically appear in QCD in the maximally Abelian gauge. These two nonperturbative phenomena simultaneously lost by removing the QCD-monopoles from the QCD vacuum generated in lattice QCD [18, 19]. This lattice QCD result surely indicates an important role of QCD-monopoles to confinement and chiral symmetry breaking, and they could have some relation through the monopole, but their direct relation is still unclear.

As an interesting example, a recent lattice study of SU(2)-color QCD with $N_f = 2$ exhibits that a confined but chiral-restored phase is realized at a large baryon density [20]. We also note that a large difference between confinement and chiral symmetry breaking actually appears in some QCD-like theories as follows:

- In an SU(3) gauge theory with adjoint-color fermions, the chiral transition occurs at much higher temperature than deconfinement, $T_{\text{chiral}} \simeq 8 \ T_{\text{deconf}}$ [21].
- In 1+1 QCD with $N_f \geq 2$, confinement is realized, whereas spontaneous chiral-symmetry breaking never occur, because of the Coleman-Mermin-Wagner theorem.
- In $N = 1$ SUSY 1+3 QCD with $N_f = N_c + 1$, while confinement is realized, chiral symmetry breaking does not occur.

In any case, the relation between confinement and chiral symmetry breaking is an important open problem in wider theoretical studies including QCD, and many studies
have been done so far [17, 18, 19, 22, 23, 24, 25, 26, 27, 28, 29].

One of the key points to deal with chiral symmetry breaking is low-lying Dirac
eigenmodes, since Banks and Casher discovered that these modes play the essential role
to chiral symmetry breaking in 1980 [9]. In this paper, keeping in mind the essential
role of low-lying Dirac modes to chiral symmetry breaking, we derive analytical relations
[26, 27, 28, 29] between the Dirac modes and the “confinement indicators”, such as
the Polyakov loop, the Polyakov-loop fluctuations [30, 31], the Wilson loop, the inter-
quark potential and the string tension, in lattice QCD formalism. Through the analyses
of these relations, we investigate the correspondence between confinement and chiral
symmetry breaking in QCD.

The organization of this paper is as follows. In Sec. 2, we briefly review the
Dirac operator, and its eigenvalues and eigenmodes in lattice QCD. In Sec. 3, we
derive an analytical relation between the Polyakov loop and Dirac modes in temporally
odd-number lattice QCD, and show independence of quark confinement from chiral
symmetry breaking. In Sec. 4, we investigate deconfinement and chiral restoration in
finite temperature QCD, through the relation of the Polyakov-loop fluctuations with
Dirac eigenmodes. In Sec. 5, we derive analytical relations of the Polyakov loop with
Wilson, clover and domain wall fermions, respectively. In Sec. 6, we express the Wilson
loop with Dirac modes on arbitrary square lattices, and investigate the string tension,
quark confining force, in terms of chiral symmetry breaking. Section 7 is devoted to
summary and conclusion.

Through this paper, we take normal temporal (anti-)periodicity for gauge and
fermion variables, i.e., gluons and quarks, as is necessary to describe the thermal system
properly, on an ordinary square lattice with the spacing $a$ and the size $V \equiv N^3 \times N_t$.
For the simple notation, we mainly use the lattice unit of $a = 1$, although we explicitly
write $a$ as necessary. The numerical calculation is done in SU(3) quenched lattice QCD.

2. Dirac operator, Dirac eigenvalues and Dirac modes in lattice QCD

In this section, we briefly review the Dirac operator $\hat{D}$, Dirac eigenvalues $\lambda_n$ and
Dirac modes $|n\rangle$ in lattice QCD, where the gauge variable is described by the link-
variable $U_{\mu}(s) = e^{iagA_{\mu}(s)} \in SU(N_c)$ with the gauge coupling $g$ and the gluon field
$A_{\mu}(x) \in \text{su}(N_c)$.

For the simple notation, we use $U_{-\mu}(s) = U_{\mu}^\dagger(s-\mu)$, and introduce the link-variable
operator $\hat{U}_{\pm\mu}$ defined by the matrix element [25, 26, 27, 28]

$$
\langle s|\hat{U}_{\pm\mu}|s'\rangle = U_{\pm\mu}(s)\delta_{s,s',\pm\mu}.
$$

which satisfies $\hat{U}_{-\mu} = \hat{U}_{\mu}^\dagger$. In lattice QCD formalism, the simple Dirac operator and the
covariant derivative operator are given by

$$
\hat{D} = \frac{1}{2a} \sum_{\mu=1}^4 \gamma_{\mu}(\hat{U}_{\mu} - \hat{U}_{-\mu}), \quad \hat{D}_\mu = \frac{1}{2a}(\hat{U}_{\mu} - \hat{U}_{-\mu}).
$$
Relating Quark Confinement and Chiral Symmetry Breaking in QCD

The Dirac operator $\hat{D}$ is anti-hermite satisfying

$$\hat{D}^{\dagger}_{s', a} = -\hat{D}_{s, s'},$$

so that its eigenvalue is pure imaginary. We define the normalized Dirac eigenmode $|n\rangle$ and the Dirac eigenvalue $\lambda_n$,

$$\hat{D}|n\rangle = i\lambda_n|n\rangle \quad (\lambda_n \in \mathbb{R}), \quad \langle m|n\rangle = \delta_{mn}. \quad (4)$$

Since the eigenmode of any (anti)hermite operator generally makes a complete set, the Dirac eigenmode $|n\rangle$ of anti-hermite $\hat{D}$ satisfies the complete-set relation,

$$\sum_n |n\rangle\langle n| = 1. \quad (5)$$

For the Dirac eigenfunction $\psi_n(s) \equiv \langle s|n\rangle$, the Dirac eigenvalue equation in lattice QCD is written as

$$\sum_{s'} \hat{D}_{s, s'} \psi_n(s') = i\lambda_n \psi_n(s), \quad (6)$$

and its explicit form is given by

$$\frac{1}{2a} \sum_{\mu=1}^{4} \gamma_\mu [U_\mu(s)\psi_n(s + \hat{\mu}) - U_{-\mu}(s)\psi_n(s - \hat{\mu})] = i\lambda_n \psi_n(s). \quad (7)$$

For the thermal system, considering the temporal anti-periodicity in $\hat{D}_4$ acting on quarks [32], it is convenient to add a minus sign to the matrix element of the temporal link-variable operator $\hat{U}_{\pm 4}$ at the temporal boundary of $t = N_t$ as [28]

$$\langle s, N_t | \hat{U}_4 | s, 1 \rangle = - U_4(s, N_t), \quad \langle s, 1 | \hat{U}_{-4} | s, N_t \rangle = - U_{-4}(s, 1) = -U_4^{\dagger}(s, N_t), \quad (8)$$

which keeps $\hat{U}_{-\mu} = \hat{U}_\mu^{\dagger}$. The standard Polyakov loop $L_P$ defined with $U_4(s)$ is simply written as the functional trace of $\hat{U}_4^{N_t}$,

$$L_P \equiv \frac{1}{N_c V} \sum_s \text{tr}_c \{ \prod_{n=0}^{N_t - 1} U_4(s + n\hat{t}) \} = - \frac{1}{N_c V} \text{Tr}_c \{ \hat{U}_4^{N_t} \}, \quad (9)$$

with the four-dimensional lattice volume $V \equiv N_s^3 \times N_t$, the functional trace $\text{Tr}_c \equiv \sum_s \text{tr}_c$, and the trace $\text{tr}_c$ over color index. The minus sign stems from the additional minus on $U_4(s, N_t)$, which reflects the temporal anti-periodicity of $\hat{D}$ [28, 32].

We here comment on the gauge ensemble average and the functional trace of operators in lattice QCD. In the numerical calculation process of lattice QCD, one first generates many gauge configurations by importance sampling with the Monte Carlo method, and next evaluates the expectation value of the operator in consideration at each gauge configuration, and finally takes its gauge ensemble average. In lattice QCD, the functional trace is expressed by a sum over all the space-time site, i.e., $\text{Tr} = \sum_s \text{tr}$, which is defined for each lattice gauge configuration. On enough large volume lattice, e.g., $N_s \to \infty$, the functional trace is proportional to the gauge ensemble average, $\text{Tr} \hat{O} = \sum_s \text{tr} \hat{O} \propto \langle \hat{O} \rangle_{\text{gauge ave.}}$, for any operator $\hat{O}$. Note also that, from the
definition of $\bar{U}_{\pm \mu}$ in Eq.(1), the functional trace of any product of link-variable operators corresponding to “non-closed line” is exactly zero, i.e.,

$$\text{Tr}(\prod_{k=1}^{N} \bar{U}_{\mu_k}) = 0 \quad \text{for} \quad \sum_{k=1}^{N} \mu_k \neq 0 \quad \mu_k \in \{\pm 1, \pm 2, \pm 3, \pm 4\},$$

(10)
at each lattice gauge configuration [26, 27, 28], before taking the gauge ensemble average.

To finalize in this section, we briefly introduce the crucial role of low-lying Dirac modes to chiral symmetry breaking. For each gauge configuration, the Dirac eigenvalue distribution is defined by

$$\rho(\lambda) \equiv \frac{1}{V} \sum_n \delta(\lambda - \lambda_n),$$

(11)
and then the Dirac zero-eigenvalue density $\rho(0)$ relates to the chiral condensate $\langle \bar{q}q \rangle$ via the Banks-Casher relation [9]

$$|\langle \bar{q}q \rangle| = \lim_{m \to 0} \lim_{V \to \infty} \pi \rho(0).$$

(12)
The quantitative importance of $\rho(0)$ to chiral symmetry breaking is actually observed in lattice QCD simulations. For example, Figs. 1(a) and (b) show the lattice QCD result of the Dirac eigenvalue distribution $\rho(\lambda)$ in confined and deconfined phases, respectively. The near-zero Dirac-mode density $\rho(\lambda \simeq 0)$ takes a non-zero finite value in the confined phase, whereas it is almost zero in the deconfined phase. In this way, the low-lying Dirac modes can be regarded as the essential modes for chiral symmetry breaking.

Figure 1. The lattice QCD result of the Dirac eigenvalue distribution $\rho(\lambda)$ in the lattice unit for (a) the confinement phase ($\beta = 5.6$, $10^3 \times 5$) and (b) the deconfinement phase ($\beta = 6.0$, $10^3 \times 5$). This figure is taken from Ref. [27].

3. Polyakov loop and Dirac modes in temporally odd-number lattice QCD

In this section, we study the Polyakov loop and Dirac modes in temporally odd-number lattice QCD [26, 27, 28], where the temporal lattice size $N_t(< N_s)$ is odd. Note that, in the continuum limit of $a \to 0$ with keeping $N_t a$ constant, any large number $N_t$ gives the same physical result. Then, it is no problem to use the odd-number lattice.

In general, only gauge-invariant quantities such as closed loops and the Polyakov loop survive in QCD, according to the Elitzur theorem [13]. All the non-closed lines are gauge-variant and their expectation values are zero. [Their functional traces are also exactly zero as Eq.(10).] Note that any closed loop needs even-number link-variables on the square lattice, except for the Polyakov loop, as shown in Fig.2.
Figure 2. (a) A simple example of the temporally odd-number lattice ($N_t = 3$ case). (b) Only gauge-invariant quantities such as closed loops and the Polyakov loop survive in QCD. Closed loops have even-number links on the square lattice.

3.1. Analytical relation between Polyakov loop and Dirac modes

On the temporally odd-number lattice, we consider the functional trace [26, 27, 28],

$$I \equiv \text{Tr}_{c,\gamma}(\hat{U}_4 \hat{D}^{N_t-1})$$

where $\text{Tr}_{c,\gamma} \equiv \sum_s \text{tr}_c \text{tr}_\gamma$ includes the sum over all the four-dimensional site $s$ and the traces over color and spinor indices. From Eq.(2), $\hat{U}_4 \hat{D}^{N_t-1}$ is written as a sum of products of $N_t$ link-variable operators, since the lattice Dirac operator $\hat{D}$ includes one link-variable operator $\hat{U}$ in each direction of $\pm \mu$. Then, $\hat{U}_4 \hat{D}^{N_t-1}$ is expressed as a sum of many Wilson lines with the total length $N_t$, as shown in Fig.3.

Figure 3. Examples of the trajectories stemming from $I = \text{Tr}_{c,\gamma}(\hat{U}_4 \hat{D}^{N_t-1})$. For each trajectory, the total length is $N_t$, and the “first step” is positive temporal direction corresponding to $\hat{U}_4$. All the trajectories with the odd-number length $N_t$ cannot form a closed loop on the square lattice, so that they are gauge-variant and give no contribution, except for the Polyakov loop.

Note that all the trajectories with the odd-number length $N_t$ cannot form a closed loop on the square lattice, and corresponding Wilson lines are gauge-variant, except for the Polyakov loop. In fact, almost all the trajectories stemming from $I = \text{Tr}_{c,\gamma}(\hat{U}_4 \hat{D}^{N_t-1})$ is non-closed and give no contribution, whereas only the Polyakov-loop component in $I$ can survive as a gauge-invariant quantity. Thus, $I$ is proportional to the Polyakov loop $L_P$. Actually, using Eqs.(9) and (10), one can mathematically derive the relation of

$$I = \text{Tr}_{c,\gamma}(\hat{U}_4 \hat{D}^{N_t-1}) = \text{Tr}_{c,\gamma}\{\hat{U}_4(\gamma_4 \hat{D}_4)^{N_t-1}\} = 4\text{Tr}_c(\hat{U}_4 \hat{D}^{N_t-1})$$
Relating Quark Confinement and Chiral Symmetry Breaking in QCD

\[ = \frac{4}{2N_t - 1} \text{Tr}_c \{ \hat{U}_4 (\hat{U}_4 - \hat{U}_{-4})^{N_t - 1} \} = \frac{4}{2N_t - 1} \text{Tr}_c \{ \hat{U}_4^{N_t} \} = -\frac{4N_c V}{2N_t - 1} L_P, \quad (14) \]

where the last minus reflects the temporal anti-periodicity of \( \hat{D} \) [28, 32].

On the other hand, using the completeness of the Dirac mode, \( \sum_n |n\rangle \langle n| = 1 \), we calculate the functional trace in Eq.(13) and find the Dirac-mode representation of

\[ I = \sum_n \langle n | \hat{U}_4 \hat{D}^{N_t - 1} | n \rangle = i^{N_t - 1} \sum_n \lambda_n^{N_t - 1} \langle n | \hat{U}_4 | n \rangle. \quad (15) \]

Combing Eqs.(14) and (15), we obtain the analytical relation between the Polyakov loop \( L_P \) and the Dirac modes in QCD on the temporally odd-number lattice [26, 27, 28],

\[ L_P = -\frac{(2i)^{N_t - 1}}{4N_c V} \sum_n \lambda_n^{N_t - 1} \langle n | \hat{U}_4 | n \rangle, \quad (16) \]

which is mathematically robust in both confined and deconfined phases. From Eq.(16), one can investigate each Dirac-mode contribution to the Polyakov loop individually.

Using the Dirac eigenvalue distribution \( \rho(\lambda) \equiv \frac{1}{V} \sum_n \delta(\lambda - \lambda_n) \), this relation can be rewritten as

\[ L_P = -\frac{(2i)^{N_t - 1}}{4N_c} \int_{-\infty}^{\infty} d\lambda \rho(\lambda) \lambda^{N_t - 1} U_4(\lambda), \quad (17) \]

with \( U_4(\lambda_n) \equiv \langle n | \hat{U}_4 | n \rangle \). Here, the Dirac zero-eigenvalue density \( \rho(0) \) relates to the chiral condensate \( \langle \bar{q}q \rangle \) via the Banks-Casher relation, \( |\langle \bar{q}q \rangle| = \lim_{m \to 0} \lim_{V \to \infty} \pi \rho(0) \) [9].

As a remarkable fact, because of the strong reduction factor \( \lambda_N^{N_t - 1} \), low-lying Dirac-mode contribution is negligibly small in RHS of Eq.(16). In Eq.(17), the reduction factor \( \lambda_N^{N_t - 1} \) cannot be cancelled by other factors, because \( \rho(0) \) is finite (not divergent) as the Banks-Casher relation suggests, and \( U_4(\lambda) \) is also finite reflecting the compactness of \( U_4 \in SU(N_c) \).

To conclude, the low-lying Dirac modes give little contribution to the Polyakov loop, regardless of confined or deconfined phase [26, 27, 28].

3.2. Properties on analytical relation between Polyakov loop and Dirac modes

In order to emphasize the importance and generality of Eq.(16), we summarize its essential properties;

(i) The relation (16) is manifestly gauge invariant, because of the gauge invariance of \( \langle n | \hat{U}_4 | n \rangle = \sum_s \langle n | s \rangle \langle s | \hat{U}_4 | s + \bar{t} \rangle \langle s + \bar{t} | n \rangle = \sum_s \psi_n(s) U_4(s) \psi_n(s + \bar{t}) \) under the gauge transformation, \( \psi_n(s) \to V(s) \psi_n(s) \).

(ii) In RHS, there is no cancellation between chiral-pair Dirac eigen-states, \( |n\rangle \) and \( \gamma_5 |n\rangle \), since \( (N_t - 1) \) is even, i.e., \( (-\lambda_n)^{N_t - 1} = \lambda_N^{N_t - 1} \), and \( \langle n | \gamma_5 \hat{U}_4 \gamma_5 | n \rangle = \langle n | \hat{U}_4 | n \rangle \).

(iii) The relation (16) is valid in a large class of gauge group of the theory, including \( SU(N_c) \) gauge theory with any color number \( N_c \).

(iv) The relation (16) is also intact regardless of presence or absence of dynamical quarks, although dynamical-quark effects appear in \( L_P \), the Dirac eigenvalue distribution \( \rho(\lambda) \) and \( \langle n | \hat{U}_4 | n \rangle \). Equation (16) remains valid at finite density and temperature.
Note here that Eq. (16) has the above-mentioned generality and wide applicability, because our derivation is based on only a few setup conditions [28]:

1. square lattice (including anisotropic cases) with temporal periodicity
2. odd-number temporal size \( N_t(< N_s) \)

In the following, we reconsider the technical merit to use the temporally odd-number lattice, i.e., absence of the loop contribution, by comparing with even-number lattices. When \( N_t \) is even, a similar argument can be applied through the relations

\[
I' \equiv \text{Tr}_{c,\gamma}(\gamma_4 \hat{U}_4 \hat{D}^{N_t-1}) = \sum_n \langle n | \gamma_4 \hat{U}_4 \hat{D}^{N_t-1} | n \rangle = i^{N_t-1} \sum_n \lambda_n^{N_t-1} \langle n | \gamma_4 \hat{U}_4 | n \rangle, \tag{18}
\]

however, apart from the Polyakov loop, there remains additional contribution from huge number of various loops (including reciprocating line-like trajectories) as

\[
I' \equiv \text{Tr}_{c,\gamma}(\gamma_4 \hat{U}_4 \hat{D}^{N_t-1}) = \frac{1}{2^{N_t-1}} \text{Tr}_{c,\gamma}[\gamma_4 \hat{U}_4 \{ \sum_{\mu=1}^{4} \gamma_\mu(\hat{U}_\mu - \hat{U}_{-\mu}) \}^{N_t-1}] = -\frac{4N_cV}{2^{N_t-1}} L_P + \text{(loop contribution)}, \tag{19}
\]

and thus one finds

\[
L_P = -\frac{(2i)^{N_t-1}}{4N_cV} \sum_n \lambda_n^{N_t-1} \langle n | \gamma_4 \hat{U}_4 | n \rangle + \text{(loop contribution)}, \tag{20}
\]

where the relation between the Polyakov loop \( L_P \) and Dirac modes is not at all clear, owing to the complicated loop contribution. In the continuum limit, both equations (16) and (20) simultaneously hold, and there appears some constraint on the loop contribution, which is not of interest. In fact, by the use of the temporally odd-number lattice, all the additional loop contributions disappear, and one gets a transparent correspondence as Eq. (16) between the Polyakov loop and Dirac modes. (For the other type of the formula on even-number lattices, see Appendix A in Ref. [26].)

3.3. Numerical analysis of the low-lying Dirac-mode contribution to the Polyakov loop

Now, we perform lattice QCD Monte Carlo calculations on the temporally odd-number lattice, and investigate the relation (16) and the low-lying Dirac-mode contribution to the Polyakov loop.

To begin with, we calculate LHS and RHS in Eq. (16) independently, and compare these values in both confined and deconfined phases [26, 27]. The Polyakov loop \( L_P \), i.e., the LHS, can be calculated in lattice QCD straightforwardly, following the definition in Eq. (9). For RHS in Eq. (16), we numerically solve the eigenvalue equation (7), and get all the eigenvalues \( \lambda_n \) and the eigenfunctions \( \psi_n(s) \). Once the Dirac eigenfunction \( \psi_n(s) \) is obtained, the matrix element \( \langle n | \hat{U}_4 | n \rangle \) can be calculated as

\[
\langle n | \hat{U}_4 | n \rangle = \sum_s \langle n | s \rangle \langle s | \hat{U}_4 | s + \hat{t} \rangle \langle s + \hat{t} | n \rangle = \sum_s \psi_n^s \hat{U}_4(s) \psi_n(s + \hat{t}).
\]

In this way, RHS is evaluated in lattice QCD. (For more technical details, see Ref. [26].)
As a numerical demonstration of Eq.(16), we calculate its LHS ($L_P$) and RHS
(Dirac spectral sum) for each gauge configuration generated in quenched SU(3) lattice
QCD, and show representative values in confined and deconfined phases in Tables 1 and
2, respectively. In both phases, one finds the exact relation $L_P = \text{RHS}$ in Eq.(16) at
each gauge configuration. [Even in full QCD, the mathematical relation (16) must be
valid, which is to be numerically confirmed in our future study.]

Next, we introduce the IR cutoff of $\Lambda_{\text{IR}} \simeq 0.4\text{GeV}$ for the Dirac modes, and remove
the low-lying Dirac-mode contribution for $|\lambda_n| < \Lambda_{\text{IR}}$ from RHS in Eq.(16). The chiral
condensate after the removal of IR Dirac-modes below $\Lambda_{\text{IR}}$ is expressed as

$$
\langle \bar{q}q \rangle_{\Lambda_{\text{IR}}} = -\frac{1}{V} \sum_{|\lambda_n| \geq \Lambda_{\text{IR}}} \frac{2m}{\lambda_n^2 + m_q^2}.
$$

In the confined phase, this IR Dirac-mode cut leads to $\frac{\langle \bar{q}q \rangle_{\Lambda_{\text{IR}}} \Lambda_{\text{IR}}}{\langle \bar{q}q \rangle} \simeq 0.02$ and almost chiral-
symmetry restoration in the case of physical current-quark mass, $m_q \simeq 5\text{MeV}$ [26].

We calculate ($L_P$)$_{\text{IR-cut}}$ with the IR Dirac-mode cutoff of $\Lambda_{\text{IR}} \simeq 0.4\text{GeV}$, and add
in Table 1 and Table 2 the results in both confined and deconfined phases, respectively.
One finds that $L_P \simeq (L_P)_{\text{IR-cut}}$ is satisfied for each gauge configuration in both phases. For the configuration average, $\langle L_P \rangle \simeq \langle (L_P)_{\text{IR-cut}} \rangle$ is of course satisfied.

From the analytical relation (16) and the numerical lattice QCD calculation, we conclude that low-lying Dirac-modes give negligibly small contribution to the Polyakov loop $L_P$, and are not essential for confinement, while these modes are essential for chiral symmetry breaking. This indicates no direct one-to-one correspondence between confinement and chiral symmetry breaking in QCD.

4. Role of Low-lying Dirac modes to Polyakov-loop fluctuations

In thermal QCD, the Polyakov loop has fluctuations in longitudinal and transverse directions, as shown in Fig.4(a), and the Polyakov-loop fluctuation gives a possible indicator of deconfinement transition [30, 31]. In this section, we investigate the Polyakov-loop fluctuations and the role of low-lying Dirac modes [27] in the deconfinement transition at finite temperatures.

For the Polyakov loop $L_P$, we define its longitudinal and transverse components,

$$L_L \equiv \text{Re} \, \tilde{L}_P, \quad L_T \equiv \text{Im} \, \tilde{L}_P,$$

with $\tilde{L}_P \equiv L_P \, e^{2\pi i k/3}$ where $k \in \{0, \pm 1\}$ is chosen such that the $Z_3$-transformed Polyakov loop lies in its real sector [27, 30, 31]. We introduce the Polyakov-loop fluctuations as

$$\chi_A \propto \langle |L_P|^2 \rangle - \langle |L_P| \rangle^2, \quad \chi_L \propto \langle L_L^2 \rangle - \langle L_L \rangle^2, \quad \chi_T \propto \langle L_T^2 \rangle - \langle L_T \rangle^2,$$

and consider their different ratios which are known to largely change around the transition temperature [30, 31], thus can be used as a good indicator of the deconfinement transition.

As an illustration, we show in Fig.4(b) the temperature dependence of the ratio $R_A \equiv \chi_A/\chi_L$. Around the transition temperature, one finds a large change of $R_A$ on the Polyakov-loop fluctuation, which reflects the onset of deconfinement, while the rapid reduction of the chiral condensate indicates a signal of chiral symmetry restoration. As a merit to use the ratio $R_A$ instead of the individual fluctuations, multiplicative-type uncertainties related to the renormalization of the Polyakov loop are expected to be cancelled to a large extent in the ratio.

Similarly in Sec. 3, we derive Dirac-mode expansion formulae for Polyakov-loop fluctuations in temporally odd-number lattice QCD [27]. For the ratios $R_A \equiv \chi_A/\chi_L$ and $R_T \equiv \chi_T/\chi_L$, we obtain their Dirac spectral representation as

$$R_A \equiv \frac{\left\langle \sum_n \lambda_n^{N_t-1} \bar{U}_{4n}^{mn} \right\rangle^2 - \left\langle \sum_n \lambda_n^{N_t-1} \bar{U}_{4n}^{nn} \right\rangle^2}{\left\langle \sum_n \lambda_n^{N_t-1} \text{Re} \left( e^{2\pi i k/3} \bar{U}_{4n}^{nn} \right) \right\rangle^2 - \left\langle \sum_n \lambda_n^{N_t-1} \text{Re} \left( e^{2\pi i k/3} \bar{U}_{4n}^{nn} \right) \right\rangle^2},$$

$$R_T \equiv \frac{\left\langle \sum_n \lambda_n^{N_t-1} \text{Im} \left( e^{2\pi i k/3} \bar{U}_{4n}^{nn} \right) \right\rangle^2 - \left\langle \sum_n \lambda_n^{N_t-1} \text{Im} \left( e^{2\pi i k/3} \bar{U}_{4n}^{nn} \right) \right\rangle^2}{\left\langle \sum_n \lambda_n^{N_t-1} \text{Re} \left( e^{2\pi i k/3} \bar{U}_{4n}^{nn} \right) \right\rangle^2 - \left\langle \sum_n \lambda_n^{N_t-1} \text{Re} \left( e^{2\pi i k/3} \bar{U}_{4n}^{nn} \right) \right\rangle^2}.$$
with \( \hat{U}_4^{nn} \equiv \langle n|\hat{U}_4|n\rangle \). We note that all the Polyakov-loop fluctuations are almost unchanged by removing low-lying Dirac modes [27] in both confined and deconfined phases, because of the significant reduction factor \( \lambda_n^{N_t-1} \) appearing in the Dirac-mode sum.

Next, let us consider the actual removal of low-lying Dirac-mode contribution from the Polyakov-loop fluctuation using Eqs. (24) and (25), and also the chiral condensate for comparison. As an example, we show in Fig.5 the lattice QCD result of

\[
R_{\text{conf}}(\Lambda_{\text{IRcut}}) \equiv \frac{R_A(\Lambda_{\text{IRcut}})}{R_A}, \quad R_{\text{chiral}}(\Lambda_{\text{IRcut}}) \equiv \frac{\langle \bar{q}q \rangle_{\Lambda_{\text{IRcut}}}}{\langle \bar{q}q \rangle}
\]

in the presence of the infrared Dirac-mode cutoff \( \Lambda_{\text{IRcut}} \) in the confined phase (\( \beta = 5.6, 10^3 \times 5 \) ) [27]. Here, \( R_A(\Lambda_{\text{IRcut}}) \) denotes the truncated value of \( R_A \) when the low-lying Dirac-mode contribution of \( |\lambda_n| < \Lambda_{\text{IRcut}} \) is removed from the Dirac spectral sum in Eq. (24). The truncated chiral condensate \( \langle \bar{q}q \rangle_{\Lambda_{\text{IRcut}}} \) is defined with Eq. (21), and the current-quark mass is taken as \( m_q = 5\text{MeV} \).

In contrast to the strong sensitivity of the chiral condensate \( R_{\text{chiral}}(\Lambda_{\text{IRcut}}) \), the Polyakov-loop fluctuation ratio \( R_{\text{conf}}(\Lambda_{\text{IRcut}}) \) is almost unchanged against the infrared cutoff \( \Lambda_{\text{IRcut}} \) of the Dirac mode [27], as discussed after Eq. (25). Thus, we find no significant role of low-lying Dirac modes for the Polyakov-loop fluctuation as a new-type confinement/deconfinement indicator, which also indicates independence of confinement from chiral property in thermal QCD.

5. Relations of Polyakov loop with Wilson, clover and domain wall fermions

All the above formulae are mathematically correct, because we have just used the Elitzur theorem (or precisely Eq. (1) for \( \hat{U}_{\pm \mu} \)) and the completeness \( \sum_n |n\rangle \langle n| = 1 \) on the eigenmode \( |n\rangle \) of the Dirac operator \( \hat{D} \) in Eq. (2). Note here that we have not introduced dynamical fermions corresponding to the simple lattice Dirac operator \( \hat{D} \), but only use
Relating Quark Confinement and Chiral Symmetry Breaking in QCD

Figure 5. The lattice QCD result of IR Dirac-mode-removed quantities of $R_{\text{conf}}(\Lambda_{\text{IRcut}}) \equiv R_A(\Lambda_{\text{IRcut}})/R_A$ and $R_{\text{chiral}}(\Lambda_{\text{IRcut}}) \equiv \langle qq \rangle_{\Lambda_{\text{IRcut}}} / \langle qq \rangle$ for $m_q = 5$ MeV, plotted against the infrared cutoff $\Lambda_{\text{IRcut}}$ introduced on Dirac eigenvalues, in quenched lattice with $\beta = 5.6$ and $10^3 \times 5$ (confined phase). This figure is taken from Ref.[27].

the mathematical eigenfunction of $\hat{D}$.

However, one may wonder the doublers [13] in the use of the lattice Dirac operator $\hat{D}$ in Eq.(2), although it is not the problem in the above formulae. In fact, according to the Nielsen-Ninomiya theorem [35], $2^d$ modes simultaneously appear per fermion on a lattice, if one uses a bilinear fermion action satisfying translational invariance, chiral symmetry, hermiticity and locality, on a $d$-dimensional lattice. Then, for the description of hadrons without the redundant doublers, one adopts Wilson, staggered, clover, domain-wall (DW) or overlap fermion [13, 36, 37, 38, 39, 40], and has to deal with the fermion kernel $K$, which is more complicated than the simple Dirac operator $\hat{D}$. In fact, the realization of a chiral fermion on a lattice is not unique. However, in the continuum limit, they must lead to the same physical result. Consequently, it is meaningful to examine our formulation with various fermion actions to get the robust physical conclusion.

In this section, we express the Polyakov loop with the eigenmodes of the kernel of the Wilson fermion, the clover ($O(a)$)-improved Wilson) fermion and the DW fermion [29]. (The formulation with the overlap fermion is found in Ref. [41].)

5.1. The Wilson fermion

A simple way to remove the redundant fermion doublers is to make their mass extremely large by an additional interaction. The Wilson fermion is constructed on a four-dimensional lattice by adding the $O(a)$ Wilson term [13], which explicitly breaks the chiral symmetry. For the Wilson fermion, all the doublers acquire a large mass of $O(a^{-1})$ and are decoupled at low energies near the continuum, $a \simeq 0$. Thus, the Wilson fermion can describe the single light fermion, although it gives $O(a)$ explicit chiral-symmetry breaking on the lattice.
The Wilson fermion kernel is described with the link-variable operator $\hat{U}_{\pm \mu}$ as [29]

$$\hat{K} = \hat{D} + m + \frac{r}{2a} \sum_{\mu = \pm 1}^{\pm 4} \gamma_\mu (\hat{U}_\mu - 1) = \frac{1}{2a} \sum_{\mu = 1}^{4} \gamma_\mu (\hat{U}_\mu - \hat{U}_{-\mu}) + m + \frac{r}{2a} \sum_{\mu = 1}^{4} \gamma_\mu (\hat{U}_\mu + \hat{U}_{-\mu} - 2),$$

(27) which goes to $\hat{K} \simeq (\hat{D} + m) + ar\hat{D}^2$ near the continuum, $a \simeq 0$. Thus, the Wilson term $ar\hat{D}^2$ is $O(a)$. The Wilson parameter $r$ is real. Note that each term of $\hat{K}$ includes one $\hat{U}_{\pm \mu}$ at most, and connects only the neighboring site or acts on the same site.

For the Wilson fermion kernel $\hat{K}$, we define its eigenmode $|n\rangle \rangle$ and eigenvalue $\tilde{\lambda}_n$,

$$\hat{K}|n\rangle \rangle = i\tilde{\lambda}_n|n\rangle \rangle, \quad \tilde{\lambda}_n \in \mathbb{C}. \quad (28)$$

If the Wilson term is absent, the eigenmode of $\hat{K} = \hat{D} + m$ is given by the simple Dirac eigenmode $|n\rangle$, i.e., $\hat{K}|n\rangle = (i\gamma_n + m)|n\rangle$, and satisfies the completeness of $\sum_n |n\rangle \langle n| = 1$.

In the presence of the $O(a)$ Wilson term, $\hat{K}$ is neither hermite nor anti-hermite, and the completeness generally includes an $O(a)$ error,

$$\sum_n |n\rangle \langle n| = 1 + O(a). \quad (29)$$

Here, we consider the functional trace $J$ on a lattice with $N_t = 4l + 1$ ($l = 1, 2, ...$),

$$J \equiv \text{Tr}(\hat{U}_4^{2l+1} \hat{K}_4^{2l}). \quad (30)$$

By the use of the quasi-completeness (29) for $|n\rangle \rangle$, one finds, apart from an $O(a)$ error,

$$J \simeq \sum_n \langle|n\rangle \langle n| \hat{U}_4^{2l+1} \hat{K}_4^{2l}|n\rangle \rangle = \sum_n (i\tilde{\lambda}_n)^{2l} \langle|n\rangle \langle n| \hat{U}_4^{2l+1}|n\rangle \rangle. \quad (31)$$

Since the kernel $\hat{K}$ in Eq. (27) is a first-order equation of the link-variable operator $\hat{U}$, $J \equiv \text{Tr}(\hat{U}_4^{2l+1} \hat{K}_4^{2l})$ is expressed as a sum of products of $\hat{U}$ with some $c$-number factor. In each product in $J$, the total number of $\hat{U}$ does not exceed $N_t = 4l + 1$, because $\hat{K}$ is a first-order equation of $\hat{U}$. Each product gives a trajectory as shown in Fig.6.

**Figure 6.** Some examples of the trajectories (corresponding to products of $\hat{U}$) in $J \equiv \text{Tr}(\hat{U}_4^{2l+1} \hat{K}_4^{2l})$ for the $N_t = 5 (l = 1)$ case. The length does not exceed $N_t$ for each trajectory. Only the Polyakov loop $L_P$ can form a closed loop and survives in $J$. 
Relating Quark Confinement and Chiral Symmetry Breaking in QCD

Among these many trajectories, only the Polyakov loop $L_P$ can form a closed loop and survives in $J$, which leads to $J \propto L_P$. Thus, apart from an $O(a)$ error, we obtain [29]

$$L_P \propto \sum_n \tilde{\lambda}^{2l}_n \langle \langle n | \hat{U}_{4}^{2l+1} | n \rangle \rangle.$$  

(32)

Using the eigenvalue distribution $\rho(\tilde{\lambda}) \equiv \frac{1}{V} \sum_n \delta(\tilde{\lambda} - \tilde{\lambda}_n)$, this relation is rewritten as

$$L_P \propto \int_{-\infty}^{\infty} d\tilde{\lambda} \rho(\tilde{\lambda}) \tilde{\lambda}^{2l} u(\tilde{\lambda}),$$

(33)

with $u(\tilde{\lambda}_n) \equiv \langle \langle n | \hat{U}_{4}^{2l+1} | n \rangle \rangle$. As in Sec.3, the reduction factor $\tilde{\lambda}^{2l}_n$ cannot be cancelled by other factors, because of the finiteness of $\rho(0)$ and $u(\tilde{\lambda})$ reflecting the Banks-Casher relation and the compactness of $U_4 \in SU(N_c)$. Thus, owing to the strong reduction factor $\tilde{\lambda}^{2l}_n$ on the eigenvalue $\tilde{\lambda}_n$ of the Wilson fermion kernel $\tilde{K}$, we find also small contribution from low-lying modes of $\tilde{K}$ to $L_P$.

5.2. The clover ($O(a)$-improved Wilson) fermion

The clover fermion is an $O(a)$-improved Wilson fermion [36] with a reduced lattice discretization error of $O(a^2)$ near the continuum, and gives accurate lattice results [37]. The clover fermion kernel is expressed as [29]

$$\tilde{K} = \tilde{D} + m + \frac{r}{2a} \sum_{\mu = \pm 1}^{+4} \gamma_\mu (\tilde{U}_\mu - 1) + \frac{\arg}{2} \sigma_{\mu\nu} G_{\mu\nu},$$

$$= \frac{1}{2a} \sum_{\mu = \pm 1}^{+4} \gamma_\mu (\tilde{U}_\mu - \tilde{U}_{-\mu}) + m + \frac{r}{2a} \sum_{\mu = 1}^{+4} \gamma_\mu (\tilde{U}_\mu + \tilde{U}_{-\mu} - 2)$$

$$+ \frac{\arg}{2} \sigma_{\mu\nu} G_{\mu\nu},$$

(34)

with $\sigma_{\mu\nu} \equiv \frac{i}{2} [\gamma_\mu, \gamma_\nu]$ and $G_{\mu\nu}$ being the clover-type lattice field strength defined by

$$G_{\mu\nu} \equiv \frac{1}{8} (P_{\mu\nu} + P_{\mu\nu}^1),$$

$$P_{\mu\nu}(x) \equiv \langle x | (\tilde{U}_\mu \tilde{U}_\nu \tilde{U}_{-\mu} \tilde{U}_{-\nu} + \tilde{U}_\nu \tilde{U}_{-\mu} \tilde{U}_{-\nu} \tilde{U}_{\mu} + \tilde{U}_{-\mu} \tilde{U}_{-\nu} \tilde{U}_\mu \tilde{U}_\nu + \tilde{U}_\nu \tilde{U}_\mu \tilde{U}_{-\nu} \tilde{U}_{-\mu}) | x \rangle.$$  

(35)

(36)

Since $G_{\mu\nu}$ acts on the same site, each term of $\tilde{K}$ in Eq.(34) connects only the neighboring site or acts on the same site. Then, the technique done for Wilson fermions is also useful.

For the clover fermion kernel $\tilde{K}$, we define its eigenmode $|n\rangle$ and eigenvalue $\tilde{\lambda}_n$ as

$$\tilde{K} |n\rangle = i\tilde{\lambda}_n |n\rangle, \quad \tilde{\lambda}_n \in \mathbb{C}, \quad \sum_n |n\rangle \langle n| = 1 + O(a^2).$$

(37)

Again, we consider the functional trace on a lattice with $N_t = 4l + 1$,

$$J \equiv \text{Tr}(\hat{U}_{4}^{2l+1} \hat{K}^{2l}) \simeq \sum_n \langle \langle n | \hat{U}_{4}^{2l+1} \hat{K}^{2l} | n \rangle \rangle = \sum_n (i\tilde{\lambda}_n)^{2l} \langle \langle n | \hat{U}_{4}^{2l+1} | n \rangle \rangle,$$

(38)

where we have used the quasi-completeness for $|n\rangle$ in Eq.(37) within an $O(a^2)$ error. $J \equiv \text{Tr}(\hat{U}_{4}^{2l+1} \hat{K}^{2l})$ is expressed as a sum of products of $\hat{U}$ with the other factor, and each product gives a trajectory as shown in Fig.6. Among the trajectories, only the Polyakov
loop \( L_P \) can form a closed loop and survives in \( J \), i.e., \( J \propto L_P \). Thus, apart from an \( O(a^2) \) error, we obtain [29]

\[
L_P \propto \sum_n \tilde{\lambda}_n^2 \langle \langle n | U_4^{2l+1} | n \rangle \rangle, \quad L_P \propto \int_{-\infty}^{\infty} d\tilde{\lambda} \rho(\tilde{\lambda}) \tilde{\lambda}^2 u(\tilde{\lambda}),
\]

(39)

with \( u(\tilde{\lambda}_n) \equiv \langle \langle n | \hat{U}_4^{2l+1} | n \rangle \rangle \) and \( \rho(\tilde{\lambda}) \equiv \frac{1}{\lambda} \sum_n \delta(\tilde{\lambda} - \tilde{\lambda}_n) \). We thus find small contribution from low-lying modes of \( \hat{K} \) to \( L_P \), because of the suppression factor \( \tilde{\lambda}_n^2 \) in the sum.

5.3. The domain wall (DW) fermion

Next, we consider the domain-wall (DW) fermion [38, 39], which realizes the “exact” chiral symmetry on a lattice by introducing an extra spatial coordinate \( x_5 \). The DW fermion is formulated in the five-dimensional space-time, and its (five-dimensional) kernel is expressed as [29]

\[
\hat{K}_5 = \hat{\Phi} + m + \frac{r}{2a} \sum_{\mu=\pm1}^4 \gamma_\mu(\hat{U}_\mu - 1) + \gamma_5 \hat{\partial}_5 + M(x_5)
\]

\[
= \frac{1}{2a} \sum_{\mu=1}^4 \gamma_\mu(\hat{U}_\mu - \hat{U}_{-\mu}) + m + \frac{r}{2a} \sum_{\mu=1}^4 \gamma_\mu(\hat{U}_\mu + \hat{U}_{-\mu} - 2) + \gamma_5 \hat{\partial}_5
\]

\[
+ M(x_5),
\]

(40)

where the last two terms are the kinetic and the mass terms in the fifth dimension. In this formalism, \( x_5 \)-dependent mass \( M(x_5) \) is introduced as shown in Fig.7, where \( M_0 = |M(x_5)| = O(a^{-1}) \) is taken to be large. Since \( \hat{K}_5 \) includes only kinetic and mass terms on the extra coordinate \( x_5 \), the eigenvalue problem is easily solved in the fifth direction. In this construction, there appear chiral zero modes [38, 39], i.e., a left-handed zero mode localized around \( x_5 = 0 \) and a right-handed zero mode localized around \( x_5 = N_5 \), as shown in Fig.7. The extra degrees of freedom in the fifth dimension can be integrated out in the generating functional, with imposing the Pauli-Villars regularization to remove the UV divergence.

For the five-dimensional DW fermion kernel \( \hat{K}_5 \), we define its eigenmode \( |\nu\rangle \) and eigenvalue \( \Lambda_\nu \) as

\[
\hat{K}_5 |\nu\rangle = i\Lambda_\nu |\nu\rangle, \quad \Lambda_\nu \in \mathbb{C}, \quad \sum_\nu |\nu\rangle \langle \nu | = 1 + O(a).
\]

(41)

Note that each term of \( \hat{K}_5 \) in Eq.(40) connects only the neighboring site or acts on the same site in the five-dimensional space-time, and we can use almost the same technique as the Wilson fermion case. We consider the functional trace on a lattice with \( N_l = 4l+1 \),

\[
J \equiv \text{Tr}(\hat{U}_4^{2l+1} \hat{K}_5^{2l}) \simeq \sum_\nu \langle \langle \nu | \hat{U}_4^{2l+1} \hat{K}_5^{2l} | \nu \rangle \rangle = \sum_\nu (i\Lambda_\nu)^{2l} \langle \langle \nu | \hat{U}_4^{2l+1} | \nu \rangle \rangle,
\]

(42)

where the quasi-completeness for \( |\nu\rangle \) in Eq.(41) is used. \( J \equiv \text{Tr}(\hat{U}_4^{2l+1} \hat{K}_5^{2l}) \) is expressed as a sum of products of \( \hat{U} \) with other factors, and each product gives a trajectory as shown in Fig.6 in the projected four-dimensional space-time. Among the trajectories, only the Polyakov loop \( L_P \) can form a closed loop and survives in \( J \), i.e., \( J \propto L_P \). Thus,
Figure 7. The construction of the domain wall (DW) fermion by introducing the fifth dimension of $x_5$ and the $x_5$-dependent mass $M(x_5)$. There appear left- and right-handed chiral zero modes localized around $x_5 = 0$ and $x_5 = N_5$, respectively.

apart from an $O(a)$ error, one finds [29]

$$L_P \propto \sum_{\nu} \Lambda_{\nu}^{2l} \langle \nu | \hat{U}_4^{2l+1} | \nu \rangle. \quad (43)$$

After integrating out the extra degrees of freedom in the fifth dimension in the generating functional, one obtains the four-dimensional physical-fermion kernel $\hat{K}_4$ [39]. The physical fermion mode is given by the eigenmode $|n\rangle$ of $\hat{K}_4$ with its eigenvalue $\tilde{\lambda}_n$,

$$\hat{K}_4 |n\rangle = i \tilde{\lambda}_n |n\rangle, \quad \tilde{\lambda}_n \in \mathbb{C}. \quad (44)$$

We find that the four-dimensional physical fermion eigenvalue $\tilde{\lambda}_n$ of $\hat{K}_4$ is approximately expressed with the eigenvalue $\Lambda_\nu$ of the five-dimensional DW kernel $\hat{K}_5$ as [29]

$$\Lambda_\nu = \tilde{\lambda}_n + O(M_0^{-2}) = \tilde{\lambda}_n + O(a^2). \quad (45)$$

Combining with Eq.(43), apart from an $O(a)$ error, we obtain [29]

$$L_P \propto \sum_{\nu} \tilde{\lambda}_n^{2l} \langle \nu | \hat{U}_4^{2l+1} | \nu \rangle, \quad (46)$$

and find small contribution from low-lying physical-fermion modes of $\hat{K}_4$ to the Polyakov loop $L_P$, due to the suppression factor $\tilde{\lambda}_n^{2l}$ in the sum.

6. The Wilson loop and Dirac modes on arbitrary square lattices

In the following, we investigate the role of low-lying Dirac modes to the Wilson loop $W$, the inter-quark potential $V(R)$ and the string tension $\sigma$ (quark confining force), on arbitrary square lattices with any number of $N_t$ [28]. We note that the ordinary Wilson loop of the $R \times T$ rectangle on the $t$-$x_k$ plane is expressed by the functional trace,

$$W \equiv \text{Tr}_c \hat{U}_k^R \hat{U}_{-k}^T \hat{U}_k^R \hat{U}_{-k}^T = \text{Tr}_c \hat{U}_{\text{staple}} \hat{U}_4^T, \quad (47)$$
where the “staple operator” \( \hat{U}_{\text{staple}} \) is defined by
\[
\hat{U}_{\text{staple}} \equiv \hat{U}_k^R \hat{U}_4^T \hat{U}_k^R.
\] (48)
In fact, the Wilson-loop operator is factorized to be a product of \( \hat{U}_{\text{staple}} \) and \( \hat{U}_4^T \), as shown in Fig.8.

6.1. Even \( T \) case

In the case of even number \( T \), we consider the functional trace,
\[
J \equiv \text{Tr}_{c,\gamma}(\hat{U}_{\text{staple}} \hat{D}^T) = \sum_n \langle n|\hat{U}_{\text{staple}}\hat{D}^T|n\rangle = (-)^{\frac{T}{2}} \sum_n \lambda_n^T \langle n|\hat{U}_{\text{staple}}|n\rangle,
\] (49)
where we use the completeness of the Dirac mode, \( \sum_n |n\rangle\langle n| = 1 \). With a parallel argument in Sec. 3, one finds at each lattice gauge configuration
\[
J = \frac{1}{2^T} \text{Tr}_{c,\gamma}[\hat{U}_{\text{staple}}\{\sum_{\mu=1}^{4} \gamma_{\mu}(\hat{U}_\mu - \hat{U}_{-\mu})\}^T] = \frac{1}{2^T} \text{Tr}_{c,\gamma}[\hat{U}_{\text{staple}}(\gamma_4 \hat{U}_4)^T]
\]
\[
= \frac{1}{2^T} \text{Tr}_c(\hat{U}_{\text{staple}} \hat{U}_4^T) = \frac{4}{2^T} W,
\] (50)
where, to form a loop in the functional trace, \( \hat{U}_4 \) has to be selected in all the \( \hat{D} \propto \sum_\mu \gamma_{\mu}(\hat{U}_\mu - \hat{U}_{-\mu}) \) in \( \hat{D}^T \). All other terms correspond to non-closed lines and give exactly zero, because of the definition of \( \hat{U}_{\pm \mu} \) in Eq.(1). We thus obtain [28]
\[
W = \frac{(-)^{\frac{T}{2}}}{4} \sum_n \lambda_n^T \langle n|\hat{U}_{\text{staple}}|n\rangle, \quad W \propto \int_{-\infty}^{\infty} d\lambda \rho(\lambda) \lambda^T U_{\text{staple}}(\lambda),
\] (51)
with \( \rho(\lambda) \equiv \frac{1}{T} \sum_n \delta(\lambda - \lambda_n) \) and \( U_{\text{staple}}(\lambda_n) \equiv \langle n|\hat{U}_{\text{staple}}|n\rangle \). As in Sec.3, the reduction factor \( \lambda^T \) cannot be cancelled by other factors, because of the finiteness of \( \rho(0) \) and \( U_{\text{staple}}(\lambda) \) reflecting the Banks-Casher relation and the compactness of \( U_{\text{staple}} \in SU(N_c) \).

Then, the inter-quark potential \( V(R) \) is given by
\[
V(R) = -\lim_{T \to \infty} \frac{1}{T} \ln\langle W \rangle = -\lim_{T \to \infty} \frac{1}{T} \ln \left| \sum_n \langle 2\lambda_n \rangle^T \langle n|\hat{U}_{\text{staple}}|n\rangle \right|, \quad (52)
\]
Relating Quark Confinement and Chiral Symmetry Breaking in QCD

where $\langle \rangle$ denotes the gauge ensemble average. The string tension $\sigma$ is expressed by

$$
\sigma = - \lim_{R,T \to \infty} \frac{1}{RT} \ln \langle W \rangle = - \lim_{R,T \to \infty} \frac{1}{RT} \ln \left| \sum_n \lambda_n^T \langle n|\hat{U}_{\text{staple}}|n \rangle \right|. 
$$

Due to the reduction factor $\lambda_n^T$ in the sum, the string tension $\sigma$ or the quark confining force is unchanged by removing low-lying Dirac-mode contributions from Eq. (53).

6.2. Odd $T$ case

In the case of odd number $T$, the similar results are obtained from

$$
J \equiv \text{Tr}_{c,\gamma}(\hat{U}_{\text{staple}} \hat{U}_4 \hat{D}^{T-1}) = \sum_n \langle n|\hat{U}_{\text{staple}} \hat{U}_4 \hat{D}^{T-1}|n \rangle
$$

$$
= (-)^{\frac{T-1}{2}} \sum_n \lambda_n^{T-1} \langle n|\hat{U}_{\text{staple}} \hat{U}_4|n \rangle. 
$$

Actually, one finds

$$
J = \frac{1}{2T-1} \text{Tr}_{c,\gamma}[\hat{U}_{\text{staple}} \hat{U}_4 \{\sum_{\mu=1}^4 \gamma_\mu(\hat{U}_\mu - \hat{U}_{-\mu})\}^{T-1}]
$$

$$
= \frac{1}{2T-1} \text{Tr}_{c,\gamma}[\hat{U}_{\text{staple}} \hat{U}_4 (\gamma_4 \hat{U}_4)^{T-1}] = \frac{4}{2T-1} \text{Tr}_{c} \hat{U}_{\text{staple}} \hat{U}_4^T = \frac{4}{2T-1} W, 
$$

and obtains for odd $T$ the similar formula [28]

$$
W = (\frac{T-1}{2})^{2T-1} \sum_n \lambda_n^{T-1} \langle n|\hat{U}_{\text{staple}} \hat{U}_4|n \rangle, 
$$

$$
W \propto \int_{-\infty}^{\infty} d\lambda \rho(\lambda) \lambda^{T-1} U(\lambda),
$$

with $U(\lambda_n) \equiv \langle n|\hat{U}_{\text{staple}} \hat{U}_4|n \rangle$.

Then, the inter-quark potential $V(R)$ and the sting tension $\sigma$ are expressed as

$$
V(R) = - \lim_{T \to \infty} \frac{1}{T} \ln \left| \sum_n (2\lambda_n)^{T-1} \langle n|\hat{U}_{\text{staple}} \hat{U}_4|n \rangle \right|, 
$$

$$
\sigma = - \lim_{R,T \to \infty} \frac{1}{RT} \ln \left| \sum_n \lambda_n^{T-1} \langle n|\hat{U}_{\text{staple}} \hat{U}_4|n \rangle \right|. 
$$

Owing to the reduction factor $\lambda_n^{T-1}$ in the sum, which cannot be cancelled by other factors, the string tension $\sigma$ is unchanged by the removal of low-lying Dirac-mode contributions from Eq. (59).

7. Summary and conclusion

In this paper, we have studied the relation between quark confinement and chiral symmetry breaking, which are the most important nonperturbative properties in low-energy QCD. In lattice QCD formalism, we have derived analytical formulae on various “confinement indicators”, such as the Polyakov loop, its fluctuations, the Wilson loop, the inter-quark potential and the string tension, in terms of the Dirac eigenmodes. We have also investigated the Polyakov loop in terms of the eigenmodes of the Wilson,
the clover and the domain-wall fermion kernels, respectively, and have derived similar formulae.

For all the relations obtained here, we have found that the low-lying Dirac modes contribution is negligibly small for the confinement quantities, while they are essential for chiral symmetry breaking. This indicates no direct, one-to-one correspondence between confinement and chiral symmetry breaking in QCD. In other words, there is some independence of quark confinement from chiral symmetry breaking.

This independence seems to be natural, because confinement is realized independently of quark masses and heavy quarks are also confined even without the chiral symmetry. Also, such independence generally lead to different transition temperatures and densities for deconfinement and chiral restoration, which may provide a various structure of the QCD phase diagram.

Acknowledgments

H.S. thanks A. Ohnishi for useful discussions. H.S. and T.M.D are supported in part by the Grants-in-Aid for Scientific Research (Grant No. 15K05076) and Grant-in-Aid for JSPS Fellows (Grant No. 15J02108) from Japan Society for the Promotion of Science. K.R. and C.S. are partly supported by the Polish Science Center (NCN) under Maestro Grant No. DEC-2013/10/A/ST2/0010. The lattice QCD calculations were done with SX8R and SX9 in Osaka University.
