Cohomological invariants mod 2 of Weyl groups

Jean-Pierre Serre

Let $G$ be the Weyl group of a root system, i.e., a crystallographic finite Coxeter group, cf. [B], chap.VI, §4.1. Let $k_0$ be a field of characteristic $\neq 2$, let $H^\bullet(k_0) = \oplus_{n \geq 0} H^n(k_0, \mathbb{F}_2)$ and let $I_G = \text{Inv}_{k_0}(G)$ be the ring of cohomological invariants mod 2 of $G$, as defined in [S], §4; it is a graded $H^\bullet(k_0)$-algebra. When $G$ is of type $A$, it is isomorphic to a symmetric group $\text{Sym}_n$, and $I_G$ is $H^\bullet(k_0)$-free of rank $1 + \lfloor n/2 \rfloor$, with an explicit basis $w_0 = 1, w_1, \ldots, w_{n/2}$, cf. [S], chap.VII.

In order to extend this description of $I_G$ to the general case, define $S_G$ to be the set of elements $g \in G$ with $g^2 = 1$; an element of $S_G$ shall be called an involution of $G$. Let $\Sigma_G$ be the set of conjugation classes of elements of $S_G$.

**Theorem A.** There exists a natural injection $e : \Sigma_G \to I_G$ whose image is an $H^\bullet(k_0)$-basis of $I_G$.

[Equivalently : the $H^\bullet(k_0)$-module $I_G$ is canonically isomorphic to the set of all maps $\Sigma_G \to H^\bullet(k_0)$.

The map $e$ is compatible with the grading of $I_G$ : if $g \in S_G$, define the degree of $g$ to be be the multiplicity of $-1$ as an eigenvalue of $g$ in the standard linear representation of $G$ as a Coxeter group; let $\Sigma_{G,n}$ be the set of involution classes of degree $n$. If $\sigma \in \Sigma_{G,n}$, then $e(\sigma)$ belongs to the $n$-th component $I_G^n$ of $I_G$.

**Examples.**

1. When $G = \text{Sym}_n$, the elements of $\Sigma_G$ are the conjugation classes of the products of $i$ disjoint transpositions, with $2i \leq n$, and we recover the fact that $H^\bullet(k_0)$-free of rank $1 + \lfloor n/2 \rfloor$, with a basis made up of elements of degree $0, 1, \ldots, \lfloor n/2 \rfloor$. In that case the canonical basis is made up of the $w_i^{\text{gal}}$, which are closely related to the $w_i$ mentioned above, cf. [S], §25.

2. When $G = \text{Weyl}(E_8)$, we have $|\Sigma_{G,n}| = 1$ for $0 \leq n \leq 8$, with the only exception of $n = 4$ where $|\Sigma_{G,n}| = 2$; and, of course, $\Sigma_{G,n} = \varnothing$ for $n > 8$. Hence $I_G$ is a free $H^\bullet(k_0)$-module of rank 10, with a basis made up of elements of degree $0, 1, 2, 3, 4, 5, 6, 7, 8$.

3. For $E_7$ and $E_6$, the degrees are $0, 1, 2, 3, 3, 4, 4, 5, 6, 7$ and $0, 1, 2, 3, 4$.

**Definition of the map** $e : \Sigma_G \to I_G$.

Let $a$ be an element of $I_G$ and let $g$ be an involution of $G$ of degree $n$. We first define a "scalar product" $\langle a, g \rangle$, which is an element of $H^\bullet(k_0)$. To do so, choose a splitting $g = s_1 \cdots s_n$, where the $s_i$ are commuting reflections (recall that a reflection is an involution of degree 1): such a splitting always exists. Let $C = (s_1, \ldots, s_n)$ be the group generated by the $s_i$, and let $a_C \in I_C$ be the image of $a$ by the restriction map $I_G \to I_C$. The algebra $I_C$ has a natural basis $(a_I)$ indexed by the subsets $I$ of $[1, n]$, cf. [S], §16.4. Let $\lambda_C \in H^\bullet(k_0)$ be the coefficient of $a_{[1, n]}$ in $a_C$ ( "top coefficient "). One can show that $\lambda_C$ is independent of the chosen splitting of $g$, i.e., that it only depends on $a$ and $g$. We then define the scalar product $\langle a, g \rangle$ as $\lambda_C$; we have $\langle a, g \rangle = \langle a, g' \rangle$ if $g$ and $g'$
are conjugate in $G$; this allows us to define $\langle a, \sigma \rangle$ for every $\sigma \in \Sigma_G$. For a given $\sigma$, the map $a \mapsto \langle a, \sigma \rangle$ is $H^\bullet(k_0)$-linear; if $a$ has degree $m$, then $\langle a, \sigma \rangle$ has degree $m - n$ (one may view $a \mapsto \langle a, \sigma \rangle$ as an $n$-th fold residue map).

**Example.** Choose for $a$ a Stiefel-Whitney class $w_i^{\text{St}}(Cox)$ of the Coxeter representation of $G$. One has $\langle a, \sigma \rangle = 0$ if $i \neq \deg(\sigma)$ and $\langle a, g \rangle = 1$ if $i = \deg(\sigma)$.

**Theorem B.**

(i) If $a \in I_G$ is such that $\langle a, \sigma \rangle = 0$ for every $\sigma$, then $a = 0$.

(ii) Let $n$ be an integer. For every $\sigma \in \Sigma_G$ of degree $n$, there exists $e(\sigma) \in I^n_G$ such that $\langle e(\sigma), \sigma \rangle = 1$ and $\langle e(\sigma), \sigma' \rangle = 0$ for every $\sigma' \neq \sigma$.

[Note that, by (i), such an $e(\sigma)$ is unique.]

It is clear that Theorem B implies Theorem A.

**Indications on the proof of part (i) of Theorem B.**

An induction argument shows that, if $\langle a, \sigma \rangle = 0$ for every $\sigma$, then the restriction of $a$ to every «cube» (i.e., subgroup generated by commuting reflections) is 0. In that case, if the characteristic of $k_0$ is good for $G$, the arguments of [S], §25, show that $a = 0$. This already covers the case where the irreducible components of $G$ are of classical type, since every characteristic $\neq 2$ is good. The exceptional types can be reduced to the classical ones, thanks to the fact that, if $G$ is such a Weyl group, there exists a subgroup $G'$ of $G$, generated by a subset of $S_G$ (hence also a Weyl group), which is of classical type, and has odd index in $G$ : for $G$ of type $E_6, E_7, E_8, F_4, G_2$, one takes $G'$ of type $D_5, A_1 \times D_4, D_8, B_4, A_1 \times A_1$, respectively ; one has $(G : G') = 27, 63, 135, 3, 3$. One then uses the fact that the restriction map $I_G \to I_{G'}$ is injective, cf. [S], prop.14.4, and that every cube of $G$ is conjugate to a cube of $G'$.

**Indications on the proof of part (ii) of Theorem B.**

We need to construct enough cohomological invariants. For most Weyl groups, this is done by using Stiefel-Whitney classes. For instance, for Weyl($E_6$), one takes the $w_i^{\text{St}}(Cox)$, $i = 0, 1, 2, 3, 4$. There are however three cases where we have to do otherwise. For each one, there are two distinct classes of involutions $\sigma, \sigma'$ of the same degree $n$ for which it is hard to find $a \in I^n_G$ with $\langle a, \sigma \rangle = 0, \langle a, \sigma' \rangle = 1$.

These cases are : $D_{2n}, n \geq 3$ ; $E_7, n = 3$ and 4 ; $E_8, n = 4$.

For those, we use the relation given by Milnor’s conjecture (now Voevodsky’s theorem) between Witt invariants and cohomological invariants mod 2. The method applies to every linear group $G$ over $k_0$. The ring $\text{Inv}_{k_0}(G, W)$ of Witt invariants of $G$ (as defined in [S], §27.3) has a natural filtration : an invariant $h$ has filtration $\geq n$ if, for every extension $k/k_0$ and every $G$-torsor $t$ of $G$ over $k$, the element $h(t)$ of the Witt ring $W(k)$ belongs to the $n$-th power of the canonical ideal of $W(k)$ ; in that case, $h$ defines (via the Milnor construction) an element $a_h$ of $\text{Inv}_{k_0}^n(G, F_2)$ which is 0 if and only if the filtration of $h$ is $> n$. We thus get an injective map $\text{gr}^n\text{Inv}_{k_0}(G, W) \to \text{Inv}_{k_0}^n(G, F_2)$.

We apply this to $G = G$, where $G$ is as in the three cases above. One can find a linear orthogonal representation of $G$ whose Brauer character $\chi$ is such that $\chi(\sigma) - \chi(\sigma') = 2^n$. This gives a $G$-quadratic form, hence an element of
Inv\(_k\)(G, W); one modifies slightly that element to make it of filtration \(\geq n\), so that it gives a cohomological invariant \(a\) of \(G\) of degree \(n\), and one checks that \(\langle a, \sigma \rangle - \langle a, \sigma' \rangle = 1\); that information is enough to conclude the proof.

**Dependence of Inv\(_k\)(G) on \(H^{\bullet}(k_0)\) - Universal objects.**

(i) *Additive structure*

For the additive structure, Inv\(_C\)(G) is a universal object, i.e., there is a natural isomorphism of \(\mathbb{F}_2\)-vector spaces: Inv\(_k\)(G) \(\simeq\) Inv\(_C\)(G) \(\otimes\mathbb{F}_2 H^{\bullet}(k_0)\).

(ii) *Ring structure*

For the ring structure, it is Inv\(_R\)(G) which is a universal object: there is a natural graded-\(\mathbb{F}_2\)-algebra isomorphism: Inv\(_k\)(G) \(\simeq\) Inv\(_R\)(G) \(\otimes_{H^{\bullet}(R)} H^{\bullet}(k_0)\).

[In this formula, \(H^{\bullet}(k_0)\) is viewed as an \(H^{\bullet}(R)\)-algebra via the unique homomorphism \(H^{\bullet}(R) \to H^{\bullet}(k_0)\) which maps the class of \(-1\) in \(H^1(R) \simeq \mathbb{R}^* / (\mathbb{R}^*)^2\) onto the class of \(-1\) in \(H^1(k_0) \simeq k_0^* / (k_0^*)^2\).]
