Abstract

Modern activation layers use non-linear functions to activate the neurons. In this paper, we present a simple but effective activation function we term ACON which learns to activate the neurons or not. Surprisingly, we find Swish, the recent popular NAS-searched activation, can be interpreted as a smooth approximation to ReLU. Intuitively, in the same way, we approximate the variants in the ReLU family to the Swish family, we call ACON, which makes Swish a special case of ACON and remarkably improves the performance. Next, we present meta-ACON, which explicitly learns to optimize the parameter switching between non-linear (activate) and linear (inactivate) and provides a new design space. By simply changing the activation function, we improve the ImageNet top-1 accuracy rate by 6.7% and 1.8% on MobileNet-0.25 and ResNet-152, respectively.

1 Introduction

The Rectified Linear Unit (ReLU) [12, 23, 38] has become an effective component in neural networks and a foundation of many state-of-the-art computer vision algorithms. Through a sequence of advances, the Swish activation [40] searched by the Neural Architecture Search (NAS) technique achieves top accuracy on the challenging ImageNet benchmark [9, 41]. It has been shown by many practices to ease optimization and achieve better performance [17, 48]. Our goal is to interpret the mechanism behind this searched result and present more effective activation functions.

Despite the success of NAS on modern activations, a natural question to ask is: how does the NAS-searched Swish actually work? We show that Swish can be surprisingly represented as a smooth approximation to ReLU, by a simple and general approximation formula (Equ. 2).

Our method, called ACON, follows the spirit of the ReLU-Swish conversion and converts the ReLU family to ACON family by the general approximation formula. We show the converted functions (ACON-A, ACON-B, ACON-C) are smooth and differentiable, where Swish is merely a case of them (ACON-A). ACON is conceptually simple and does not add any computational overhead, however, it improves accuracy remarkably. To achieve this result, we identify the fixed upper/lower bounds in the gradient as the main obstacle impeding from improving accuracy and present the ACON with learnable upper/lower bounds.

Intuitively, ACON is an extension of the ReLU-Swish conversion, learning to switch between activating or not by optimizing the switching factor. However, evidence has shown that optimizing the parameter directly cannot learn to switch between linear and non-linear well. Therefore, we optimize the switching factor explicitly for fast learning and present meta-ACON that learns to learn whether to activate or not (see Fig. 1). Despite it seems a minor change, meta-ACON has a large impact: it improves the accuracy on various structures (even the highly-optimized and extremely deep SENet-154) and provides a new architecture design space in the meta learner, which could be layer-wise,
Figure 1: We present ACON that learns to adaptively activate the neurons or not. **Left:** ReLU network; **Right:** ACON network that learns to activate (orange) or not (white).

channel-wise, or pixel-wise. The design in the provided space is beyond the focus of this paper, but it is suggestive for future research.

We summarize our contributions as follows: (1) We find the NAS-searched Swish can be interestingly interpreted as a smooth approximation to ReLU; (2) In the same way, we approximate the ReLU family to be smooth and present ACON family as simple but effective activations; (3) We present meta-ACON that explicitly learns to activate the neurons or not, improves the performance remarkably, and enables a new architecture design space.

To demonstrate the effectiveness of ACON, we show by experiments on the challenging ImageNet [9, 41] task that ACON has significant improvement: it improves the ImageNet top-1 accuracy rate by 6.7% and 1.8% on MobileNet-0.25 and ResNet-152, respectively. The uncertainty of the activating degree in each layer also acts as a regularizer that can benefit generalization, and we demonstrate the generalization on object detection and semantic segmentation tasks.

## 2 Related Work

**Activation layer** The Rectified Linear Unit (ReLU) [12, 23, 38] and its variants [36, 14, 7, 34] are the most widely used activation functions in the past few years. ReLU is non-differentiable at zero and is differentiable anywhere else. Many advances followed [26, 44, 1, 16, 39, 11, 54], and softplus [10] is a smooth approximation to the maximum function ReLU based on the LogSumExp function.

The recent searching technique contributes to a new searched scalar activation called Swish [40] by combing a comprehensive set of unary functions and binary functions. The form is $y = x \cdot \text{Sigmoid}(\beta x)$, outperforms other scalar activations on some structures and datasets, and many searched results show great potential. However, there is a lack of proper explanation of Swish. In this paper, we generalize Swish to the ACON family, showing that it is a smooth version of ReLU based on the well-known smooth conversion called $\alpha$-softmax, which is frequently applied in optimization and neural computation [27, 3, 13].

**Dynamic network** Standard convolution networks [43, 15, 46, 58, 6, 18, 42, 17] share the same network structure and convolution kernels for all the samples, while conditional (or dynamic) CNNs [28, 31, 53, 57, 25, 33] use dynamic kernels, widths, or depths conditioned on the input samples, obtaining remarkably gains in accuracy.

Some dynamic networks learn the dynamic kernels [55, 33], some use attention-based approaches [49, 32, 2, 50, 52, 19] to change the network structures, another series of work [51, 20] focus on dynamic depths of the convolutional networks, that skip some layers for different samples. In our work, we learn the non-linear degree in the activation function dynamically, which controls to what degree the non-linear layer is.

**Neural network design space** The design of the neural network architecture mainly includes the kernel level space and the feature level space. The most common feature design space aims to optimize the performance via channel dimension [46, 97, 42, 35, 19], spatial dimension [48, 4, 22]...
We observe that Swish is a smooth approximation to ReLU. Therefore we consider the case when \( \beta \) is the switching factor, we introduce meta-ACON that learns to optimize the factor explicitly and shows significant improvements.

**Smooth maximum** We begin by briefly reviewing the smooth maximum function. Consider a standard maximum function \( \max(x_1, \ldots, x_n) \) of \( n \) values, we have its smooth and differentiable approximation:

\[
S_\beta(x_1, \ldots, x_n) = \frac{\sum_{i=1}^{n} x_i e^{\beta x_i}}{\sum_{i=1}^{n} e^{\beta x_i}}
\]

where \( \beta \) is the switching factor: when \( \beta \to \infty, S_\beta \to \max \); when \( \beta \to 0, S_\beta \to \text{arithmetic mean} \).

In neural networks, many common activation functions are in the form of \( \max(\eta_a(x), \eta_b(x)) \) function (e.g. ReLU \( \max(x, 0) \) and its variants) where \( \eta_a(x) \) and \( \eta_b(x) \) denote linear functions. Our goal is to approximate the activation functions by this formula. Therefore we consider the case when \( n = 2 \), we denote \( \sigma \) as the Sigmoid function and the approximation becomes:

\[
S_\beta(\eta_a(x), \eta_b(x)) = \eta_a(x) \cdot \frac{e^{\beta \eta_a(x)}}{e^{\beta \eta_a(x)} + e^{\beta \eta_b(x)}} + \eta_b(x) \cdot \frac{e^{\beta \eta_b(x)}}{e^{\beta \eta_a(x)} + e^{\beta \eta_b(x)}}
\]

\[
= \eta_a(x) \cdot \frac{1}{1 + e^{-\beta(\eta_a(x) - \eta_b(x))}} + \eta_b(x) \cdot \frac{1}{1 + e^{-\beta(\eta_b(x) - \eta_a(x))}}
\]

**ACON-A** We consider the case of ReLU when \( \eta_a(x) = x, \eta_b(x) = 0 \), then \( f_{\text{ACON-A}}(x) = S_\beta(x, 0) = x \cdot \sigma(\beta x) \), which we call ACON-A and is exactly the formulation of Swish [40]. Swish is a recent new activation which is a NAS-searched result, although it is widely used recently, there is a lack of reasonable explanations about why it improves the performance. From the perspective above, we observe that Swish is a smooth approximation to ReLU.
ACON-B  Intuitively, based on the approximation we could convert other maximum-based activations in the ReLU family (e.g. Leaky ReLU [36], PReLU [14], etc) to the ACON family. Next, we show the approximation of PReLU. It has an original form \( f(x) = \max(x, 0) + p \cdot \min(x, 0) \), where \( p \) is a learnable parameter and initialized as 0.25. However, in most case \( p < 1 \), under this assumption, we rewrite it to the form: \( f(x) = \max(x, px)(p < 1) \). Therefore we consider the case when \( \eta_a(x) = x, \eta_b(x) = px \) in Equ. 2 and get the following new activation we call ACON-B:

\[
f_{\text{ACON-B}}(x) = S_\beta(x, px) = (1 - p)x \cdot \sigma[\beta(1 - p)x] + px
\]  

ACON-C  Intuitively, we present a simple and more general case we term ACON-C. We adopt the same two-argument function, with an additional hyper-parameter. ACON-C follows the spirit of ACON-B that simply uses hyper-parameters scaling on the feature. Formally, let \( \eta_a(x) = p_1 x, \eta_b(x) = p_2 x (p_1 \neq p_2) \):

\[
f_{\text{ACON-C}}(x) = S_\beta(p_1 x, p_2 x) = (p_1 - p_2)x \cdot \sigma[\beta(p_1 - p_2)x] + p_2 x
\]  

Our definition of ACON-C is a very simple and general case (see Fig. 2, Fig. 3). Moreover, there could be many more complicated cases in the ReLU family (e.g. more complicated formulations of \( \eta_a(x) \) and \( \eta_b(x) \)), which are beyond the scope of this paper. We focus on the property of the conversion on this simple form.

Upper/lower bounds in the first derivative.  We show that Swish has fixed upper/lower bounds (Fig. 2 b) but our definition of ACON-C allows the gradient has learnable upper/lower bounds (Fig. 2 c). Formally, we compute the first derivative of ACON-C and its limits as follows:

\[
\frac{d}{dx}[f_{\text{ACON-C}}(x)] = \frac{(p_1 - p_2)(1 + e^{-\beta(p_1 x - p_2 x)}) + \beta(p_1 - p_2)^2 e^{-\beta(p_1 x - p_2 x))}x}{(1 + e^{-\beta(p_1 x - p_2 x))}^2} + p_2
\]  

\[
\lim_{x \to \infty} \frac{df_{\text{ACON-C}}(x)}{dx} = p_1, \quad \lim_{x \to -\infty} \frac{df_{\text{ACON-C}}(x)}{dx} = p_2 \quad (\beta > 0)
\]  

To compute the upper/lower bounds, which are the maxima/minima values, we compute the second derivative:

\[
\frac{d^2}{dx^2}[f_{\text{ACON-C}}(x)] = \frac{\beta (p_2 - p_1)^2 e^{\beta(p_1 - p_2)x} ((\beta (p_2 - p_1) x + 2) e^{\beta(p_1 - p_2)x} + \beta (p_1 - p_2) x + 2)}{(e^{\beta(p_1 - p_2)x} + 1)^3}
\]
We set $\frac{d^2}{dx^2}[f_{\text{ACON-C}}(x)] = 0$, simplify it, and get $(y - 2)e^y = y + 2$, where $y = (p_1 - p_2)\beta x$. Solving the equation we get $y \approx \pm 2.39936$. Then we get maxima and minima of Equ. [5]

\[
\begin{align*}
\text{maximal } & \frac{d}{dx}[f_{\text{ACON-C}}(x)] \approx 1.0998p_1 - 0.0998p_2, \\
\text{minimal } & \frac{d}{dx}[f_{\text{ACON-C}}(x)] \approx 1.0998p_2 - 0.0998p_1 \hspace{10pt} (\beta > 0)
\end{align*}
\]

This is different from Swish with the fixed upper/lower bounds (1.0998, -0.0998) in the first derivative. In Swish, the hyper-parameter $\beta$ only determines how fast the first derivative asymptotes to the upper bound and the lower bound, however, the bounds are learnable and determined by $p_1$ and $p_2$ in ACON-C (see Fig. [2]c). The learnable boundaries are essential to ease optimization and we show by experiments that these learnable upper/lower bounds are the key for improved results.

### Table 1: Summary of the ReLU family and ACON family. $\sigma$ denotes Sigmoid.

| $\eta_a(x)$ | $\eta_b(x)$ | $\max(\eta_a(x), \eta_b(x))$ | $\sigma((\eta_a(x) - \eta_b(x)) \cdot \beta \eta_b(x)) + \eta_b(x)$ |
|-----|-----|-----------------|------------------------------------------------|
| $x$ | 0 | $\max(x, 0)$ : ReLU | ACON-A (Swish) : $x \cdot \sigma(\beta x)$ |
| $x$ | $px$ | $\max(x, px)$ : PReLU | ACON-B : $(1 - p)x \cdot \sigma(\beta(1 - p)x) + px$ |
| $p_1 x$ | $p_2 x$ | $\max(p_1 x, p_2 x)$ | ACON-C : $(p_1 - p_2)x \cdot \sigma(\beta(p_1 - p_2)x) + p_2 x$ |

### 3.1 Meta-ACON

ACON switches the activation to activate or not as the switching factor $\beta$ controls it to be non-linear or linear. Specifically, when $\beta \rightarrow \infty$, $f_{\text{ACON-C}}(x) \rightarrow \max(p_1 x, p_2 x)$; when $\beta \rightarrow 0$, $f_{\text{ACON-C}}(x) \rightarrow \text{mean}(p_1 x, p_2 x)$. Thus, unlike the traditional activations such as the ReLU family, ACON allows each neuron to adaptively activate or not (see Fig. [1]). This customized activating behavior helps to improve generalization and transfer performance. This motivated us to develop the following meta-ACON that plays a key role in the customized activation.

Our proposed concept is simple: learning the switching factor $\beta$ explicitly conditioned on the input sample $x \in \mathbb{R}^{C \times H \times W}$; $\beta = G(x)$. We are not aiming to propose a specific structure, we provide a design space in the generating function $G(x)$.

#### Design space

The concept is more important than the specific architecture which can be layer-wise, channel-wise of pixel-wise structure. Our goal is to present some simple designing examples, which manage to obtain significantly improved accuracy and show the importance of this new design space.

We briefly use a routing function to compute $\beta$ conditioned on input features and present some simple structures. First, the structure can be layer-wise, which means the elements in a layer share the same switching factor. Formally, we have: $\beta = \sigma \sum_{c=1}^{C} \sum_{h=1}^{H} \sum_{w=1}^{W} x_{c,h,w}$.

Second, we present a simple channel-wise structure, meaning the elements in a channel share the same switching factor. Formally, we show it by: $\beta_c = \sigma W_1 W_2 \sum_{h=1}^{H} \sum_{w=1}^{W} x_{c,h,w}$. We use $W_1 \in \mathbb{R}^{C \times C/r}$, $W_2 \in \mathbb{R}^{C/r \times C}$ to save parameters ($r = 16$ by default).

Third, for the pixel-wise structure, all the elements use unique factors. Although there could be many structure designing methods, we simply present an extremely simple structure aiming to present a pixel-wise example. Formally, we have: $\beta_{c,h,w} = \sigma x_{c,h,w}$.

We note that our meta-ACON has a straightforward structure. For the following meta-ACON experiments, we use the channel-wise structure and ACON-C unless otherwise noted. More complex designs have the potential to improve performance but are not the focus of this work.
Table 2: Comprehensive comparison of ACON on MobileNets, ShuffleNetV2 and ResNets. We report the top-1 error on the ImageNet dataset (train and test on 224x224 input size).

| Model          | MobileNet | MobileNetV2 | ShuffleNetV2 | ResNet  |
|----------------|-----------|-------------|--------------|---------|
| Channel / depth| 0.25      | 0.75        | 0.17         | 1.0     | 0.5x    | 1.5x | Res-18 | Res-50 | Res-101 |

4 Experiment

4.1 Image Classification

We present a thorough experimental comparison on the challenging ImageNet 2012 classification dataset [9, 41] along with comprehensive ablations. For training, we follow the common practice and train all the models using the same input size of 224x224 and report the standard top-1 error rate.

ACON We first evaluate our ACON method on the light-weight CNNs (MobileNets [18, 42] and ShuffleNetV2 [35]) and deep CNNs (ResNets [15]). For light-weight CNNs we follow the training configure in [35]; for the larger model ResNet, we use linear decay learning rate schedule from 0.1, a weight decay of 1e-4, a batch size of 256, and 600k iterations. We run numerous experiments to analyze the behavior of the ACON activation function, by simply changing all the activations on various network structures and various model sizes. The baseline networks are the ReLU networks and the extra parameters in ACON networks are negligible.

We have two major observations from Table 2 and Fig. 2. (i), ACON-A, ACON-B, and ACON-C all improve the accuracy remarkably comparing with their max-based functions. This shows the benefits of the differentiable and smooth conversion. (ii), ACON-C outperforms ACON-A (Swish) and ACON-B, benefitting from the adaptive upper/lower bounds in the ACON-C’s first derivatives. (iii), Although ACON-A (Swish) shows minor improvements as the models go deeper and larger (0.1% on ResNet-101), we still obtain continuous accuracy gains from ACON-C (0.7% on ResNet-101).

Meta-ACON Next, we evaluate the meta-ACON function. For light-weight CNNs we change all the ReLU activations to meta-ACON, for deep CNN (ResNet-50, ResNet-101) we change one ReLU (after the 3x3 convolution) in each building block to meta-ACON to avoid the overfitting problem.

The results in Table 3 show that we manage to obtain remarkably accuracy gains in all the network structures. For light-weight CNNs, meta-ACON improves 6.7% on MobileNetV1 0.25 and still has
Table 4: **Comparison with other activations.** We report the top-1 error on the ImageNet dataset.

| Activation | Top-1 err. |
|------------|------------|
| ReLU       | 39.4       |
| Swish      | 38.3       |
| Mish       | 39.5       |
| ELU        | 39.5       |
| SoftPlus   | 39.6       |
| ACON-C     | 37.0       |
| meta-ACON  | 34.8       |

Table 5: **Design space in meta-ACON.** We report the top-1 error on the ImageNet dataset. Comparison on 3 different levels of design space. We give 3 most simple examples on ShuffleNetV2 0.5x. $f_c$ denotes fully-connected, $\sigma$ denotes sigmoid, GAP denotes global average pooling.

| manner       | Top-1 err. |
|--------------|------------|
| baseline     | -          | 39.4       |
| pixel-wise   | $\sigma(x)$ | 37.2       |
| channel-wise | $\sigma(f_c[f_c[GAP(x)]]))$ | 34.8       |
| layer-wise   | $\sigma(\sum_c GAP(x))$ | 36.3       |

Table 6: **Meta-ACON vs. SENet [19].** We report the ImageNet top-1 error rates of ShuffleNetV2 and ResNet.

| Baseline     | SE | meta-ACON |
|--------------|----|-----------|
| ShuffleNetV2 0.5x | 39.4 | 37.5 | **34.8** |
| ShuffleNetV2 1.5x | 27.4 | 26.4 | **24.7** |
| ResNet-50    | 24.0 | 22.8 | **22.0** |
| ResNet-101   | 22.8 | 21.9 | **21.1** |
| ResNet-152   | 22.3 | 21.5 | **20.5** |

Table 7: **Comparison on the extremely deep SENet-154 [19].** We report the ImageNet top-1 error rates. We implement all the models by ourselves.

| Activation | Top-1 err. |
|------------|------------|
| ReLU       | 18.95      |
| ACON-A (Swish) | 19.02 |
| meta-ACON  | 18.40      |

around 3% accuracy gains on 300M level models. For deeper ResNets, meta-ACON still shows significant improvements, which are 2.0% and 1.7% on ResNet-50 and ResNet-101.

To reveal the reasons, in Fig. 4 we select a layer in the last bottleneck and compare the learned $\beta$ distribution in ResNet-50. ACON shares the same $\beta$ distribution for all the different samples across the dataset, however, in meta-ACON different samples have distinct non-linear degrees instead of sharing the same non-linear degree in ACON. Specifically, some samples tend to have more values close to zero, which means for such samples the network tends to have a lower non-linear degree. While some samples tend to have more values far from zero, meaning the network adaptively learns a higher non-linearity for such samples. This is an intuitively reasonable result as different samples usually have quite different characteristics and properties.

4.2 Ablation Study

We run several ablations to analyze the proposed ACON and meta-ACON activations.

Comparison with other activations  Table 4 show the comparison with more activations besides ReLU and Swish, including Mish [37], ELU [7], SoftPlus [10]. We note that recent advances show comparable results comparing with ReLU, except that Swish shows greater improvement (1.1% top-1 error rate). ACON and meta-ACON manage to improve the accuracy remarkably (2.4% and 4.6%) comparing with the previous activations.

Design space in meta-ACON  We provide a new architecture design space in meta-ACON ($G(x)$ in Sec. 3.1). As the switching factor determines the non-linearity in the activation, we generate $\beta$ values for each sample on different levels, which could be pixel-wise, channel-wise, and layer-wise. Our goal is to present a wide design space that provides more possibilities in the future neural network design, we are not aiming to propose the most effective specific module in this paper, which is worth more future studies. We investigate the most simple module for each level that is described in Section 3.1 Table 5 shows the comparison on ShuffleNetV2 0.5x. The results show that all three levels could improve accuracy significantly, with more careful design, there could be more effective modules.

Switching factor distribution  In meta-ACON we adopt a meta-learning module to learn the switching factor $\beta$ explicitly. Figure 4 shows the distribution of the learned factor in the last activation layer of ResNet-50, we compare meta-ACON with ACON, and randomly select 7 samples to show the result.
Table 8: Comparison of different activations on the COCO object detection [30] task. We report results on RetinaNet [29] with ResNet-50 backbones.

|        | mAP | AP$_{50}$ | AP$_{75}$ | AP$_{S}$ | AP$_{M}$ | AP$_{L}$ |
|--------|-----|-----------|-----------|----------|----------|----------|
| ReLU   | 35.2| 53.7      | 37.5      | 18.8     | 39.7     | 48.8     |
| Swish  | 35.8| 54.1      | 38.7      | 18.6     | 40.0     | 49.4     |
| meta-ACON | 36.5| **55.9**  | **38.9**  | **19.9** | **40.7** | **50.6** |

Table 9: Comparison of different activations on the CityScape [8] semantic segmentation task. We report results on PSPNet [59] with ResNet-50 backbones.

| Activation | FLOPs | # Params. | mean_IU |
|------------|-------|----------|---------|
| ReLU       | 3.9G  | 25.5M    | 77.2    |
| Swish      | 3.9G  | 25.5M    | 77.5    |
| meta-ACON  | 3.9G  | 25.7M    | **78.3**|

The distributions indicate three conclusions: (1) meta-ACON learns a more widespread distribution than ACON; (2) each sample has its own switching factor instead of sharing the same one; (3) some samples have more values close to zero, meaning some neurons tend not to activate in this layer.

Comparison with SENet We have shown that ACON helps improving accuracy remarkably. Next, we compare our channel-wise meta-ACON with the effective module SENet [19] on various structures. We conduct a comprehensive comparison of both light-weight CNNs and deep CNNs. Table 6 shows that meta-ACON outperforms SENet significantly on all the network structures. We note that it is more difficult to improve accuracy on larger networks because of highly optimized, but we find that even in the extreme deep ResNet-152, meta-ACON still improves accuracy by 1.8%, which gains 1% comparing with SENet.

Moreover, we conduct experiments on the highly optimized and extremely large network SENet-154 [19], which is challenging to further improve the accuracy. We re-implement SENet-154 and change the activations to ACON under the same experimental environment for fairness comparison. We note that SE together with ACON-A or ACON-C is a case of channel-wise meta-ACON structure, the differences between them are the learnable upper/lower bounds (see Sec.3). Table 7 shows two results: first, simply combing ACON-A (Swish) with SENet performs comparable or even worse result comparing to ReLU activation; second, ACON-C achieves 18.40 top-1 error rate on the challenging ImageNet dataset, improving the performance remarkably.

4.3 Generalization

Our framework can easily be extended to other tasks, we show by experiments on object detection and semantic segmentation that it has good generalization performance.

COCO object detection We report the standard COCO [30] metrics including AP (averaged over IoU thresholds), AP$_{50}$, AP$_{75}$, AP$_{S}$, AP$_{M}$, AP$_{L}$ (AP at different scales). We train using the union of 80k train images and a 35k subset of validation images (trainval35k) and report results on the remaining 5k validation images (minival). We choose the RetinaNet [29] as the detector and use ResNet-50 as the backbone. As a common practice, we use a batch size of 2, a weight decay of 1e-4, and a momentum of 0.9. We use anchors for 3 scales and 3 aspect ratios and use a 600-pixel train and test image scale. To evaluate the results of different activations, we use the ImageNet pre-trained ResNet-50 with different activations as backbones. Table 8 shows the significant improvements comparing with other activations.

Semantic segmentation We further present the semantic segmentation results on the CityScape dataset [8]. We use the PSPNet [59] as the segmentation framework and ResNet-50 as the backbone. As a common practice, we use the poly learning rate policy where the base is 0.01 and the power is 0.9, a weight decay of 1e-4, and a batch size of 16. Table 9 shows that our result (78.3) is 1.1 points
higher than the ReLU baseline, showing larger improvement than Swish. Given the effectiveness of our method on various tasks, we expect it to be a robust and effective activation for other tasks.

5 Conclusion

In this work, we present ACON as a general and effective activation that learns to activate or not. We show ACON family that approximates to the ReLU family, exploring more functions in the ReLU family is a promising future direction yet beyond the focus of this work. Moreover, to explicitly learn the switching factor that switches between linear and non-linear, we present meta-ACON that also provides a wide design space. Our approach is simple but highly effective, we demonstrate its efficacy on light-weight models and even improve the accuracy remarkably on the highly optimized deep SENet-154. We expect this robust and effective activation applied to a wide range of applications.
