Abstract. In this work, we extend and analyze the nonperturbative Maxwell-Schrödinger-Plasma (MASP) model. This model was proposed to describe the high order optical nonlinearities, and the low density free electron plasma generated by a laser pulse propagating in a gas. The MASP model is based on nonasymptotic, ab-initio equations, and accurately uses self-consistent description of micro (quantum)- and macro (field)- variables. However, its major drawback is a high computational cost, which in practice means that only short propagation lengths can be calculated. In order to reduce this cost, we study the MASP models enriched by a macroscopic evolution equation for polarization, from its simplest version in a form of transport equation, to more complex nonlinear variants. We show that homogeneous transport equation is a more universal tool to simulate the high harmonic spectra at shorter times and/or at a lower computational cost, while the nonlinear equation could be useful for modeling the pulse profiles when the ionization level is moderate. The gain associated with the considered modifications of the MASP model, being expressed in reduction of computational time and the number of processors involved, is of 2-3 orders of magnitude.

Key words. Maxwell-Schrödinger-Plasma equations, nonlinear optics, high harmonic generation, laser-filamentation

1. Introduction. The discovery of attosecond pulses [17, 34] and of laser filaments [12] has led to the need for an appropriate mathematical description of the evolution of ultrashort, that is only few-optical-cycles, laser pulses. Perturbative methods based on the approximate equations, e.g. Nonlinear Schrödinger Equation (NLSE)-type, although advantageous for not too short pulses, have essential intrinsic restrictions when applied to ultrashort pulses. These issues were addressed in some key papers [11, 19, 21]. Over the years, several advanced models were proposed, and we refer to a set of review papers [8, 16, 25]. Certain complex models, e.g. including High Order Kerr Effect (HOKE) and Unidirectional Pulse Propagation Equation (UPPE) [2, 24], allow for accurate simulations and analysis of laser filamentation in some physical regimes [2, 7, 13, 26, 42, 48]. However, an appropriate modeling of free-electron plasma generated by the ultrashort intense laser pulse, as well as of nonperturbative evolution of the pulse in nonlinear media, is still an open problem that is only partially addressed [5, 6, 23, 35, 39, 40, 43, 45].

Now we briefly specify the principal features of the standard models used to study filament propagation [3, 8, 25]. In a broad sense, there are two general standard approaches to describe short-pulse propagation in a nonlinear medium [36, 38]:

- models considering the evolution of the envelope of the electromagnetic wave. As a rule, they are based on time-dependent NLSE, and the second generation equations, e.g. the Nonlinear Envelope Equation (NEE) [10];
- models based on full electric field propagators. It is the set of equations connected with Korteweg-de Vries (KdV) equation, e.g. the UPPE [38].

Applied to nonlinear optics, both “parental” equations, NLSE and KdV, as well as
their descendants, are reductions obtained under some assumptions from Maxwell’s equations. To describe the linear and nonlinear response of the medium, the perturbative expansion for polarization vector with the susceptibility coefficients $\chi^{(2m+1)}$ was used [9]. In the strict sense, one can classify standard models as perturbative, even if they account HOKE [8].

Summing up, despite the quite reliable description of the evolution of the ultrafast laser pulses and relatively low computational cost, both standard approaches (i) use approximate but not exact propagation equations; (ii) employ perturbative expansion for the polarization; (iii) receive the frequency-property of the medium as an external parameters; (iv) compute free electron density phenomenologically [8, 25]. All these properties suggest that the solution of the problem can be improved and the involvement of non-standard nonperturbative models will be highly useful. The fully self-consistent mathematical model must include side by side [27, 29]:

- Maxwell’s equations (MEs) modeling the evolution of the laser field under the response of the molecules in the gas region where the pulse propagates;
- the set of time-dependent Schrödinger equations (TDSEs), which describes the interaction of the molecules with an electromagnetic field of the pulse;
- kinetic equations, in order to take into account the dynamics of the generated free-electron plasma.

In practice, the realization of such Maxwell-Schrödinger-Plasma (MASP) model [27] faces extremely high computational cost for solving the system of TDSEs, and requires high performance computing. Nevertheless, over the past 10 years important results have been achieved within this model, and the studies are in progress, see e.g. [27, 28, 29, 31, 32]. Namely, it was suggested [30, 31] to enrich the MASP model by a macroscopic transport equation modeling the nonperturbative polarization. It was demonstrated that this approach allows to reduce drastically the number of microscopic TDSEs in the model thus making the numerical computation of the model much faster. The goals of this paper is (i) to justify mathematically well-posedness of the thus supplemented MASP model, and (ii) to derive more accurate and sophisticated evolution equations.

This paper is organized as follows. In Section 2, we derive the MASP equations enriched by the evolution equations modeling the propagation of the polarization. Section 3 is devoted to the mathematical analysis of the enriched model. Numerical approximation and parallel computing aspects are addressed in Section 4. Several numerical experiments are presented in Section 5. We finally conclude in Section 6.

2. MASP Model and its Development. The usual spatial setting is as follows: the electromagnetic pulse propagates in sequence through 3 regions: vacuum, molecule-gas and again vacuum. As soon as the wave envelope gets into the last vacuum region, the electric field components in space and time are stored. The starting point is a micro-macro model constituted by MEs coupled with several TDSEs, describing the nonlinear response of gas subject to an electromagnetic field [27, 28, 29]. More precisely, to simulate the macroscopic propagation effects, we use the differential form of Ampere-Maxwell’s and Faraday-Maxwell’s laws in a bounded spatial domain $\Omega$, with a smooth boundary $\partial \Omega$. We define $\mathbf{x}' = (x', y', z')^T$ the electromagnetic field space variable, then for nonmagnetic medium, $\mathbf{B} = \mathbf{H}$:

\[
\begin{align*}
\partial_t \mathbf{E}(\mathbf{x}', t) &= \varepsilon \nabla \times \mathbf{B}(\mathbf{x}', t) - 4\pi (\partial_x \mathbf{P}(\mathbf{x}', t) + \mathbf{J}(\mathbf{x}', t)), \\
\partial_t \mathbf{B}(\mathbf{x}', t) &= -\varepsilon \nabla \times \mathbf{E}(\mathbf{x}', t).
\end{align*}
\]
Thus, to compute from (1a) and (1b) the electromagnetic field vectors $\mathbf{E}(\mathbf{x}', t)$ and $\mathbf{B}(\mathbf{x}', t)$, we need to determine the polarization $\mathbf{P}(\mathbf{x}', t)$ and the current density $\mathbf{J}(\mathbf{x}', t)$ vectors from the microscopic equations.

We will consider interaction between a molecule, typically $\text{H}_2^+$ for simplicity, and the field in the dipole approximation, which is valid when the smallest internal wavelengths $\lambda_{\text{min}}$ of the electromagnetic field are much larger than the molecule size $\ell$ (in the same direction), that is $\ell \ll \lambda_{\text{min}}$. Typically we have $\lambda_{\text{min}} \approx 800$ nm (Ti:Sapphire laser) and for $\text{H}_2^+$-molecule size $\ell \approx 0.1$ nm. The simple molecule $\text{H}_2^+$ possesses two advantages: it has only one electron, and is symmetric with respect to the point bisecting the interval between the nucleus. It follows the symmetry of the Hamiltonian with respect to the electron coordinate inversion: $\mathbf{x} \rightarrow -\mathbf{x}$, which allows to reduce formally the problem of describing the dynamics of 3 particles, to a 2-body problem, and hence the exact Schrödinger equation can be numerically considered [28]. However, in practice, even more complex molecules like $\text{O}_2$, $\text{N}_2$ could as well be considered within the MASP, using the single active electron approximation (SAE), [41].

Although in its whole generality the MASP model for $\text{H}_2^+$ includes the motion of the 3 particles [28], we will use the Born-Oppenheimer approximation throughout the article. It is a typical approximation in quantum chemistry, since the time-scale for dynamics of the interatomic electrons (attoseconds) is much shorter then the time-scale for the nuclei motion (femtoseconds) [14, 37, 50]. At the molecular (microscopic) scale, we will denote by $\mathbf{x} = (x, y, z)^T$ the TDSEs space variable (that is for electron wavefunctions). The components of the polarization vector $\mathbf{P}(\mathbf{x}', t)$, be to substituted into MEs (1a) and (1b), are computed using a trace operator [27]:

\begin{align}
(2a) \quad & \mathbf{P}(\mathbf{x}', t) = N(\mathbf{x}') \sum_{i=1}^{m} \mathbf{P}_i(\mathbf{x}', t) = -N(\mathbf{x}') \sum_{i=1}^{m} \chi_{\Omega_i}(\mathbf{x}') \int_{\mathbb{R}^3} \psi_i^*(\mathbf{x}, t) \mathbf{x} \psi_i(\mathbf{x}, t) d\mathbf{x}, \\
(2b) \quad & i \partial_t \psi_i(\mathbf{x}, t) = -\frac{\Delta}{2} \psi_i(\mathbf{x}, t) + V_C(\mathbf{x}) \psi_i(\mathbf{x}, t) + \mathbf{x} \cdot \mathbf{E}(\mathbf{x}', t) \psi_i(\mathbf{x}, t), \quad \forall i \in \{1, \ldots, m\},
\end{align}

where $V_C$ denotes the static interaction potential. The density of ionic molecule $\text{H}_2^+$ is taken to be smooth in space, and is denoted by $N(\mathbf{x}')$. It must be approximately equal to the initial electrons number density $N_{\text{eo}}(\mathbf{x}')$ [15], and can be assumed constant in time in case of low level of ionization. For example, let the ionic $\text{H}_2^+$-molecule be oriented in the plane $(x, y)$ of the selected Cartesian system, then the nuclear potential is written as:

\begin{equation}
V_C(\mathbf{x}) = -\left[\left(x - \frac{R_0}{2} \cos \theta \right)^2 + \left(y - \frac{R_0}{2} \sin \theta \right)^2 + z^2\right]^{-1/2} - \left[\left(x + \frac{R_0}{2} \cos \theta \right)^2 + \left(y + \frac{R_0}{2} \sin \theta \right)^2 + z^2\right]^{-1/2},
\end{equation}

where $\theta \in [0^\circ, 90^\circ]$ defines the angle between the molecular axis of $\text{H}_2^+$ and the $x$-axis, with an internuclear distance $R_0$; in our computations it usually equals to 2 atomic units (a.u.), corresponding to $\approx 0.1$ nm, see e.g. [50].

Solving of the TDSEs (2b) provides a complete set of the wavefunctions, which in its turn allows to evaluate the ionization level of a gas and obtain a continuum spectrum of free electrons propagating in a laser pulse. We define the spatial domain $\Omega = \cup_{i=1}^{m} \Omega_i$, where $\Omega_i$ denotes the macroscopic spatial domain containing a molecule of reference associated to a wavefunction $\psi_i$, while in (2a) $\mathbf{P}_i(t) = \chi_{\Omega_i} \mathbf{d}_i(t)$ denotes the macroscopic polarization in this domain, and the index $i$ is associated to the specific coordinate of MEs, $\mathbf{x}'$. Functions $\chi_{\Omega_i}$ are defined as $\chi \otimes 1_{\Omega_i}$, where $\chi$ is
a plateau, and \(1_{\Omega_i}\) is the characteristic function of \(\Omega_i\). Also \(d_i(t)\) is a microscopic time-dependent dipole moment of a molecule belonging to \(\Omega_i\):

\[
d_i(t) = -\int_{\mathbb{R}^3} \psi_i^*(x,t)x\psi_i(x,t)d^3x.
\]

In other words, the domain \(\Omega_i\) contains \(N(x')\text{vol}(\Omega_i)\) molecules represented by one single wavefunction \(\psi_i\) (under the assumption of a unique pure state [27]). We now assume that the spatial support of \(\psi_i\) is included in a domain \(\omega_i \subset \mathbb{R}^3\). We allow free electrons to reach the boundary \(\partial \omega_i\), where we impose artificial complex potential, see e.g. [18]. Thus, in the discussed model, the part of the wavefunction absorbed at the boundary generates the plasma of free electrons. Finally in (2b), \(E_{x_i}\) denotes the electric field (supposed to be constant within \(\omega_i\)).

To close the set of equations, the current density evolution equation can be integrated in the system via the Drude model [8, 28] on the MEs domain:

\[
\partial_t J(x',t) + \nu_e J(x',t) = N_e(x',t)E(x',t),
\]

where \(\nu_e\) denotes the effective electron collision frequency. In the MASP model \(N_e(x',t)\) is computed from molecular ionization self-consistently:

\[
N_e(x',t) = N_{e0}(x') + N(x') \sum_{i=1}^{m} \chi_{\Omega_i}(x')I_i(t),
\]

where the function

\[
I_i(t) = 1 - \int_{\Omega_i} |\psi_i(x,t)|^2 d^3x
\]
defines a fraction of the electrons freed due to tunnel ionization [22, 1], using the \(L^2\)-norm of the bound electron wavefunctions.

**Remark 2.1.** Equations (1a), (1b), (2a), (2b), and (5) form the MASP model.

In general, for 1-electron TDSE and under Born-Oppenheimer approximation, the MASP model is 3d-3d in the sense, that \(E(x',t), B(x',t)\) and \(\psi(x,t)\) are functions of spatial coordinates: \(x' = (x', y', z')^T\) and \(x = (x, y, z)^T\). More generally, in the terminology \(M_d-N_d\), \(M = \dim(x')\) and \(N = \dim(x)\). In practice, we can reduce the computational complexity of the system by applying a reasonable dimensionality reduction. For example, Figure 1 illustrates domain decomposition in case of 1d-2d MASP model with the pulse propagating in the \(z'\)-direction.

However, if we want to describe the medium response to a laser pulse within the MASP model accurately, a very large number of TDSEs is required, increasing immensely the overall computational cost of the model. With the purpose to reduce this cost, Lorin et al. [30, 31] have proposed to enrich the MASP model by a simple transport equation for polarization:

\[
\partial_t P(x',t) + v_g \partial_{z'} P(x',t) = 0,
\]

where \(v_g\) is the group velocity. More specifically, the MEs domain is now decomposed along the \(z'\)-direction in \(N_1\) subdomains, each containing \(N_2\) layers transversal to \(z'\)-axis with thickness \(\Delta z'\). For the 3d MEs, the dimensionality of such a layer is 2: plane \((x', y')\), while in case of 1d MEs the “layer” degenerates to the cell,
whose transversal dimension is 0. In order to locally evaluate the dipole moment, the TDSEs are computed only at first layers (or cells) of each subdomain with coordinates denoted $x'_{\alpha,1}$, where $\alpha = 1, \ldots, N_1$, and the second index is for the number of layer/cell within the subdomain. Thus, we can add to (8) the initial value of polarization $P(x'_{\alpha,1},0) = N(x'_{\alpha,1})d(x'_{\alpha,1},0)$. Between these first layers/cells, the evolution equations on $P$, such as (8), are used for a “cheap” computation (as fully macroscopic) of the polarization vector. For the 1d-2d MASP model this methodology is summarized in Figure 2.

Note that this model is applicable as long as the length $\Delta_{\alpha}z'$ of the subdomains along $z'$-axis is short enough, or/and if the molecule density is low enough. That is, as long as the effect of the medium on $E$ during the pulse propagation from $x'_{\alpha,1}$ to $x'_{\alpha+1,1}$ is sufficiently negligible not to be included in the dipole moment calculation of a molecule located at $x'_{\alpha+1,1}$. In order to include the medium effects on $E$ during the propagation in $(x'_{\alpha,1}, x'_{\alpha+1,1})$, an improvement of the model is necessary.

The approach we propose here allows to consider larger propagation lengths and times more accurately than the simple transport equation. Since we consider multidimensional EM field propagation, including forward and backward propagation effects,
the equation for polarization is expected to be of the form:

$$\partial_t^2 \mathbf{P} - v_g^2 \nabla \mathbf{P} = \mathbf{S}(\mathbf{E}),$$

(9)

where for brevity sake we denote $\mathbf{P} \equiv \mathbf{P}(\mathbf{x}', t)$, $\mathbf{E} \equiv \mathbf{E}(\mathbf{x}', t)$. The main idea consists of including as much information as possible to determine $\mathbf{S}(\mathbf{E})$ in (9). Cancelling out $\mathbf{B}$ from (1a) and (1b), we get the wave equation for $\mathbf{E}$:

$$\partial_t^2 \mathbf{E} - c^2 \nabla \mathbf{E} + c^2 \nabla(\nabla \cdot \mathbf{E}) = -4\pi(\partial_t^2 \mathbf{P} + \partial_t \mathbf{J}).$$

(10)

We omit the term $\nabla(\nabla \cdot \mathbf{E})$, supposing that on the relevant propagation length non-linearity is not very strong, as $\nabla \cdot \mathbf{E} \propto \nabla \cdot \mathbf{P}^{NL}$ [9]:

$$\partial_t^2 \mathbf{E} - c^2 \nabla \mathbf{E} = -4\pi(\partial_t^2 \mathbf{P} + \partial_t \mathbf{J}).$$

(11)

Next, we assume that the perturbative expansion

$$\mathbf{P}(\mathbf{x}', t) = \chi^{(1)} \mathbf{E}(\mathbf{x}', t) + \chi^{(3)}(\mathbf{E}(\mathbf{x}', t) \cdot \mathbf{E}(\mathbf{x}', t))\mathbf{E}(\mathbf{x}', t),$$

(12)

where $\chi^{(1)}$ and $\chi^{(3)}$ are the first and third instantaneous susceptibilities of isotropic medium is an accurate approximation for $\mathbf{P}$ at least for short enough propagation length. From here

$$\mathbf{E}(\mathbf{x}', t) = \frac{1}{\chi^{(1)}} \mathbf{P}(\mathbf{x}', t) - \frac{\chi^{(3)}}{\chi^{(1)}}(\mathbf{E}(\mathbf{x}', t) \cdot \mathbf{E}(\mathbf{x}', t))\mathbf{E}(\mathbf{x}', t).$$

(13)

Then substituting (13) in (11) leads to

$$(1 + 4\pi\chi^{(1)})\partial_t^2 \mathbf{P} - c^2 \nabla \mathbf{P} = \chi^{(3)} \left[ \partial_t^2 \mathbf{E}(\mathbf{E} \cdot \mathbf{E}) - c^2 \nabla(\mathbf{E} \cdot \mathbf{E}) \right] - 4\pi\chi^{(1)}\partial_t \mathbf{J},$$

(14)

where $(\mathbf{E} \cdot \mathbf{E}) = E_x^2 + E_y^2 + E_z^2$. The group velocity in the first approximation can be defined as $v_g = c/\sqrt{1 + 4\pi\chi^{(1)}}$ [31], so that the evolution equation for $\mathbf{P}$ is shaped into

$$\partial_t^2 \mathbf{P} - v_g^2 \nabla \mathbf{P} = \left( \frac{v_g}{c} \right)^2 \chi^{(3)} \left[ \partial_t^2 (\mathbf{E} \mathbf{E}) - c^2 \nabla(\mathbf{E} \mathbf{E}) \right] - 4\pi\chi^{(1)}\partial_t \mathbf{J}.\tag{15}$$

At preselected locations, say $\mathbf{x}_\alpha'$ ($\alpha = 1, 2 \ldots N_1$) and at each computational time step $t_\beta$, the data $\mathbf{P}(\mathbf{x}_\alpha', t_\beta)$, $\partial_t \mathbf{P}(\mathbf{x}_\alpha', t_\beta)$ are computed from microscopic TDSEs:

$$\begin{cases}
\mathbf{P}(\mathbf{x}_\alpha', t_\beta) = N(\mathbf{x}_\alpha') \int_{\mathbb{R}^3} \left| \psi_{\mathbf{x}_\alpha'}(\mathbf{x}, t_\beta) \right|^2 \mathbf{x} d\mathbf{x}, \\
\partial_t \mathbf{P}(\mathbf{x}_\alpha', t_\beta) = N(\mathbf{x}_\alpha') \int_{\mathbb{R}^3} \partial_t \left| \psi_{\mathbf{x}_\alpha'}(\mathbf{x}, t_\beta) \right|^2 \mathbf{x} d\mathbf{x}.
\end{cases}$$

(16)

Recall that the current density $\mathbf{J}$ satisfies the macroscopic kinetic equation (5). Let the free electron density be a function of the $z'$-coordinate, the direction of the pulse propagation, and time. It is reasonable then to compute this value from the following transport equation:

$$\partial_t N_e(z', t) + v_g \partial_{z'} N_e(z', t) = 0,$$

(17)

with the initial distribution computed according to (6) and (7):

$$N_e(z'_\alpha, t_\beta) = N_e(0) + N(z'_\alpha) \sum_{i=1}^m \chi_{i\alpha}(z'_\alpha) \left[ 1 - \int_{\Omega_i} |\psi_i(\mathbf{x}, t_\beta)|^2 d^3\mathbf{x} \right].$$

(18)

Thus, except for the evaluation of the polarization and the free electron number density at specific locations, requiring TDSE computations, the evolution equations (15) and (17) are then fully macroscopic.
Remark 2.2. Equations (1a), (1b), and (5) defined on a bounded spatial domain \(\Omega\), being coupled to the evolution equations for polarization (15) (or in the simplest case, to equation (8)) and to the evolution equations for free electron density (17) with respective initial conditions (16) and (18), computed at the set of preselected locations of \(\Omega\) through the TDSEs (2b), form the enriched MASP model.

It is necessary to comment the philosophy of the proposed approach. Equations (15) with initial conditions (16) form a nonperturbative model, which includes (i) the transport of nonperturbative data (as \(\partial_t P_0\) are computed from TDSEs) from the left boundary to the right one of each subdomain, and (ii) the perturbative corrections to polarization within these subdomains. In (8), we do not assume propagation in a linear medium, however, we use a linear approximation that is valid when the length of the subdomain is short enough, and the same was assumed while deriving (15) from (11) and (12). Thus, in our model approach the LHS in the equation (15) represents the linear transport of the nonperturbative polarization \(\partial_t P(\mathbf{x}',\cdot)\) initially taken from the nonperturbative computations (16) at reference points \(\mathbf{x}'_\alpha,\, \alpha = 1, \ldots, N_1\), across the subdomains. The RHS of the equation (15) makes the non-zero perturbative corrections to the polarization in interval \(\Delta x_\alpha z'\).

For practical purposes, we simplify the polarization evolution equation in the case of 1d-2d model, moreover we will consider the case of linearly polarized pulse, implying that \(P_{x'}(z', t)\) as well as \(E_{x'}(z', t)\) are null. Thus, assuming that the polarization vector propagates along the \(z'\)-direction (Laplacian \(\Delta\) is reduced to \(\partial_z^2\)) we obtain an evolution equation for \(P_{y'}\):

\[
\frac{\partial^2}{\partial t^2} P_{y'} - v_y^2 \frac{\partial^2}{\partial z^2} P_{y'} = 3\chi^3 \left(\frac{v_g}{c}\right)^2 E_{y'}^2 \partial_t^2 E_{y'} - c^2 \partial_z^2 E_{y'} + 6\chi^3 \left(\frac{v_g}{c}\right)^2 E_{y'} \left[\partial_t E_{y'}^2 - c^2 (\partial_z E_{y'})^2\right] - 4\pi \chi (\frac{v_g}{c})^2 \partial_t J_{y'}.
\]

For the sake of simplicity of the notation we introduce three variable factors

\[
\begin{align*}
a(E_{y'}(z', t)) & := 1 + 12\pi \chi^3 \left(v_g/c\right)^2 E_{y'}^2, \\
b(E_{y'}(z', t)) & := 6\chi^3 \left(v_g/c\right)^2 E_{y'}, \\
g(E_{y'}(z', t)) & := 4\pi \chi^3 (v_g/c)^2 (\chi (1) + 3\chi^3 E_{y'}^2),
\end{align*}
\]

and observing that \(\partial_z^2 E_{y'} - c^2 \partial_z^2 E_{y'} = -4\pi \partial_t^2 P_{y'} - 4\pi \partial_t J_{y'}\) in 1d, the polarization wave equation takes the form

\[
a(E_{y'}) \frac{\partial^2}{\partial t^2} P_{y'} - v_y^2 \partial_z^2 P_{y'} = b(E_{y'}) \left[\partial_t E_{y'}^2 - c^2 (\partial_z E_{y'})^2\right] - g(E_{y'}) \partial_t J_{y'}.
\]

Recall that we want to couple this equation to the MASP model. However, the RHS of (21) contains partial derivatives of the electric field in time, and this fact may result in some sort of computational instability. To avoid possible instability of the solution, we replace in (21) \(\partial_t E_{y'} = c \partial_{z'} B_{z'} - 4\pi \partial_t P_{y'} - 4\pi J_{y'}\) according to (1a), thus

\[
a(E_{y'}) \partial_t^2 P_{y'} - v_y^2 \partial_{z'}^2 P_{y'} + 8\pi b(E_{y'}) \left[(c \partial_{z'} B_{z'} - 4\pi J_{y'})(\partial_t P_{y'}) - 2\pi (\partial_t P_{y'})^2\right] = b(E_{y'}) \left[c^2 \left((\partial_{z'} B_{z'})^2 - (\partial_z E_{y'})^2\right) + 8\pi J_{y'} \left(2\pi J_{y'} - c \partial_{z'} B_{z'}\right)\right] - g(E_{y'}) \partial_t J_{y'}.
\]

Finally, we provide the principal details of the procedure leading to the 1d-2d enriched MASP model.
• At $t = t_\beta$, all the time derivatives of polarization $\partial_t P_{\psi'}(z'_{\alpha,1}, t_\beta)$ are computed at locations with coordinates $z'_{\alpha,1}$, $\alpha = 1, \ldots, N_1$, from the set of TDSEs (2b) according to (16), see Figure 2;

• These data are used as boundary conditions for the wave equation (22) with $\partial_z B_{\psi'}(z', t_\beta)$ and $\partial_z E_{\psi'}(z', t_\beta)$ in the RHS, in order to compute the time derivative of polarization $\partial_t P_{\psi'}(z'_{\alpha,\mu}, t_{\beta+1})$ ($\alpha = 1, \ldots, N_1$, $\mu = 2 \ldots N_2$) at time $t_{\beta+1}$ and at all other locations $\{z'_{\alpha,\mu}\}$ of the MEs domain;

• Thus, at time $t_{\beta+1}$ we have $\partial_t P_{\psi'}(z'_{\alpha,1}, t_{\beta+1})$, computed using the TDSEs, and $\partial_t P_{\psi'}(z'_{\alpha,\mu}, t_{\beta+1})$ ($\mu = 2 \ldots N_2$), computed using the polarization evolution equation. We use these data to solve the MEs (1a) and (1b) in the domain at time $t_{\beta+1}$.

Finally we note that in the case of linearly polarized pulses, it is easy to generalize (20) including higher order nonlinearities:

$$
\begin{align*}
\alpha(E_{\psi'}) &:= 1 + 4\pi(v_g/c)^2(3\chi^{(3)}E_{\psi'}^2 + 5\chi^{(5)}E_{\psi'}^4 + 7\chi^{(7)}E_{\psi'}^6 + \ldots), \\
b(E_{\psi'}) &:= E_{\psi'}(v_g/c)^2(6\chi^{(3)} + 20\chi^{(5)}E_{\psi'}^2 + 42\chi^{(7)}E_{\psi'}^4 + \ldots), \\
g(E_{\psi'}) &:= 4\pi(v_g/c)^2(\chi^{(1)} + 3\chi^{(3)}E_{\psi'}^2 + 5\chi^{(5)}E_{\psi'}^4 + 7\chi^{(7)}E_{\psi'}^6 + \ldots) = \\
&= 4\pi(v_g/c)^2\chi^{(1)} + [a(E_{\psi'})]^{-1} - 1.
\end{align*}
$$

3. Existence and uniqueness of the weak solutions for the MASP models. In this section, we study the well-posedness of the MASP models. We start the analysis with the MASP model, see Remark 2.1, which we will also refer to as the “pure” MASP model (in contrast to the “enriched” model). We base our proof on the results that were established earlier for the Schrödinger equation [4, 20, 27] and the Maxwell-Schrödinger model [28], which does not include the description of the plasma effects. Then, we discuss the existence and regularity of solutions to the model supplemented by the evolution equations for polarization (9), and for the free electrons density (17).

3.1. Pure MASP Model. Let $(E_0, B_0, J_0, \overline{\psi_0})^T$ be the initial data of the equations (1a), (1b), (2b), and (5), where $\overline{\psi_0} = (\psi_{0,1} \ldots \psi_{0,m})^T$, and $m$ is the total number of cells in the gas region. We suppose that $E_0, B_0, J_0$ belong to $(H^1(\Omega))^3$, where

• $\Omega \subset \mathbb{R}^3$ is a bounded spatial domain for Maxwell’s equations with a smooth boundary $\partial \Omega$ where Dirichlet zero BCs be imposed for $E, B, J$. In other words, we assume that the electromagnetic pulse remains always inside the domain $\Omega$, so that for all time the flux of the Poynting vector $S = \frac{c}{4\pi}E \times B$ (recall, in our case $B \equiv H$) at the boundary $\partial \Omega$ is zero as well;

• $H^1(\Omega)$ denotes the Sobolev space $W^{1,2}(\Omega)$ [47]:

$$
H^1(\Omega) = \{v \in L^2(\Omega) \mid \partial_{x_i} v_{\mathcal{D}'} \in L^2(\Omega), \ i = 1, 2, 3\},
$$

where the derivative $\partial_{x_i} v_{\mathcal{D}'}$ is defined in the distributional (weak) sense, and $L^p$ ($1 \leq p < +\infty$) denote the Lebesgue spaces. Further in this section, we will omit the symbol $\mathcal{D}'$ on the derivatives, for the sake of simplicity of the notation.

In the Born-Oppenheimer approximation the distance between nuclei $R_0 > 0$ is a fixed parameter of the wavefunctions. We suppose that $\overline{\psi_0} \in (H^1(\mathbb{R}^3) \cap H_1(\mathbb{R}^3))^m$, where the norm of the Sobolev space $H^1(\mathbb{R}^3)$ reads

$$
\|\psi\|^2_{H^1} = \int_{\mathbb{R}^3} |(\psi(x, R_0)|^2 + \sum_{i=1}^3 |\partial_{x_i} \psi(x, R_0)|^2) dx.
$$
The norm of another Sobolev space $H_1$ (with low index), which is the image of $H^1$ (with upper index) under the Fourier transform $[4, 47]$, is defined as:

\begin{equation}
\|\psi\|_{H_1}^2 = \int_{\mathbb{R}^3} (1 + |(x, R_0)|^2)|\psi(x, R_0)|^2 \, dx,
\end{equation}

where $|(x, R_0)|^2 := |x - R_0|^2 = |x - e_0 R_0|^2$ with unit vector $e_0$ that defines the orientation of the molecule in plane $(x, y)$.

Now we extend the Existence and Uniqueness Theorem [28], referred to solutions of the Maxwell-Shrödinger (MS) model, to the case of MASP model.

**Theorem 3.1.** Suppose that $(E_0, B_0, J_0) \in (H^1(\Omega))^3 \times (H^1(\Omega))^3 \times (H^1(\Omega))^3$, $\psi_0 \in (H^1 \cap H_1)^m$, $R_0 > 0$ is a constant for all $t \in \mathbb{R}$ and $J \in C_0^\infty(\Omega)$. Suppose that on the smooth boundary $\partial \Omega$ zero Dirichlet BCs are imposed on vectors $E, B, J$ for all $t \in \mathbb{R}$. Then there exists a time $T > 0$, and a unique solution $(E, B, J, \psi) \in (L^\infty(0, T; (H^1(\Omega))^3) \cap H^1(0, T; (L^2(\Omega))^3))^3 \times L^\infty(0, T; (H^1 \cap H_1)^m)$ to Equations (1a), (1b), (2b), and (5).

In order to prove this theorem, we should prove several important intermediate results. The first lemma follows closely [28] and [4].

**Lemma 3.2.** Suppose that $E(x', \cdot) \in L^\infty(0, T)$ and $\partial_t E(x', \cdot) \in L^1(0, T)$ for $x'$ fixed in $\Omega$. We assume that $R_0 > 0$ is fixed for all $t \in \mathbb{R}$. Then for all $\psi_{0, i} \in H^1 \cap H_1$, there exists $\psi_i \in L^\infty(0, T; H^1 \cap H_1)$ solution to the Schrödinger equation (2b), and there exists a constant $C_T > 0$ such that

$$
\|\psi_i\|_{L^\infty(0, T; H^1 \cap H_1)} \leq C_T \|\psi_{0, i}\|_{H^1 \cap H_1}.
$$

The proof can be found in [28].

The next lemma from [28] generalizes the result of Lemma 3.2, on the vector-valued function $\bar{\psi} = (\psi_1 \ldots \psi_m)^T$:

**Lemma 3.3** (Lorin et al. [28]). Suppose given $E(x', \cdot) \in L^\infty(0, T)$ and $\partial_t E(x', \cdot) \in L^1(0, T)$ for $x'$ fixed in $\Omega$. Then there exists $C_T > 0$, such that for all $\bar{\psi}_0 \in (H^1 \cap H_1)^m$ there exists a solution $\bar{\psi} \in L^\infty(0, T; (H^1 \cap H_1)^m)$ and

$$
\|\bar{\psi}\|_{L^\infty(0, T; (H^1 \cap H_1)^m)} \leq C_T \|\bar{\psi}_0\|_{(H^1 \cap H_1)^m}.
$$

**Proof.** It follows from the previous lemma.

**Lemma 3.4** (Lorin et al. [28]). For all $T > 0$, and $\bar{\psi} \in L^\infty(0, T; (H^1 \cap H_1)^m)$, $P \in L^\infty(0, T; (C_0^\infty(\mathbb{R}))^3)$.

**Proof.** Recall that $\chi_{\Omega_0}, N$ belong to $C_0^\infty(\Omega)$ and $\psi_i \in L^\infty(0, T; H^1 \cap H_1)$, for all $i = 1, \ldots, m$, we then deduce that

$$
t \mapsto \int_{\mathbb{R}^3 \times \mathbb{R}^+} \psi_i^*(R_0, x, t) x \psi_i(R_0, x, t) \in L^\infty(0, T).
$$

In particular for all $i = 1, \ldots, m$, as $\psi_i$ belongs to $H^1 \cap H_1$, and the integral is defined. Finally, by definition of polarization (2a):

$$
P(x', t) = -N(x') \sum_{i=1}^m \chi_{\Omega_0} \int_{\mathbb{R}^3} \psi_i^*(R_0, x, t) x \psi_i(R_0, x, t) \, dx \, dR_0,
$$

which concludes the proof.
Lemma 3.5 (Lorin et al. [28]). For \( x' \) fixed in \( \Omega \) and \( T > 0 \), \( \partial_t \mathbf{P}(x', \cdot) \in \mathcal{L}_0^\infty(0, T) \) and \( \partial_t (\nabla \cdot \mathbf{P}(x', \cdot)) \in \mathcal{L}_0^\infty(0, T) \).

Proof. First, we observe that \( \partial_t \mathbf{P}(x', t) = \mathcal{N}(x') \sum_{i=1}^m \partial_t \mathbf{P}_i(x', t) \), where

\[
\partial_t \mathbf{P}_i(x', t) = \chi_\Omega(x') \int_{\mathbb{R}^3} \partial_t \psi_i^0(R_0, x, t) \psi_i(R_0, x, t) d\mathbf{R}_0 + \\
+ \chi_\Omega(x') \int_{\mathbb{R}^3} \psi_i^0(R_0, x, t) \partial_t \psi_i(R_0, x, t) d\mathbf{R}_0.
\]

As \( \psi_i \in \mathcal{L}_0^\infty(0, T; H^1 \cap H_1) \) and \( \chi_\Omega, \mathcal{N} \in \mathcal{C}_0^\infty(\Omega) \) then \( \partial_t \mathbf{P}_i \in \mathcal{L}_0^\infty(0, T) \) for all \( i = 1, \ldots, m \), hence \( \partial_t \mathbf{P} \in \mathcal{L}_0^\infty(0, T) \). Also as, according to Lemma 3.4, \( \nabla \cdot \mathbf{P}(\cdot, t) \in \mathcal{C}_0^\infty(\Omega) \) at \( t \) fixed, we also have that \( \partial_t (\nabla \cdot \mathbf{P})(x', \cdot) \in \mathcal{L}_0^\infty(0, T) \).

Lemma 3.6. Suppose given \( \mathcal{N}_e \in \mathcal{C}_0^\infty \), then for all \( T > 0 \), and \( v \in \mathcal{L}_0^\infty(0, T; (H^1 \cap H_1)^m) \), \( \mathcal{N}_e \in \mathcal{L}_0^\infty(0, T; \mathcal{C}_0^\infty) \).

Proof. We know that \( \mathcal{N} \) and \( \chi_\Omega \) being to \( \mathcal{C}_0^\infty \). Following Equations (6), (7), the expression for density of free electron \( \mathcal{N}_e(x', t) \) at different \( x' \) reads

\[
\mathcal{N}_e(x', t) = \mathcal{N}_0(x') + \mathcal{N}(x') \sum_{i=1}^m \chi_\Omega(x') \left( 1 - \int_{\Omega_i} |\psi_i(R_0, x', t)|^2 d\mathbf{R}_0 \right) d\mathbf{R}_0,
\]

which proves the lemma.

Lemma 3.7. Suppose that \( \mathbf{E}(t)|_{\partial \Omega} = \mathbf{B}(t)|_{\partial \Omega} = 0 \in \mathbb{R}^3 \), then for all \( T > 0 \) and \( \Omega \subset \mathbb{R}^3 \)

\[
\|\mathbf{E}(\cdot, T)\|_{L^2(\Omega)}^2 + \|\mathbf{B}(\cdot, T)\|_{L^2(\Omega)}^2 = \|\mathbf{E}_0(\cdot)\|_{L^2(\Omega)}^2 + \|\mathbf{B}_0(\cdot)\|_{L^2(\Omega)}^2 - \\
8\pi \int_0^T \int_{\Omega} \mathbf{E}(x', t) \cdot \partial_t \mathbf{P}(x', t) d\mathbf{x}' dt - 8\pi \int_0^T \int_{\Omega} \mathbf{E}(x', t) \cdot \mathbf{J}(x', t) d\mathbf{x}' dt,
\]

and

\[
\|\nabla \cdot \mathbf{E}(\cdot, T)\|_{L^2(\Omega)}^2 = \|\nabla \cdot \mathbf{E}_0(\cdot)\|_{L^2(\Omega)}^2 - 8\pi \int_0^T \int_{\Omega} \nabla \cdot \mathbf{E}(x', t) \partial_t \nabla \cdot \mathbf{P}(x', t) d\mathbf{x}' dt - \\
8\pi \int_0^T \int_{\Omega} \nabla \cdot \mathbf{E}(x', t) \nabla \cdot \mathbf{J}(x', t) d\mathbf{x}' dt.
\]

Proof. We respectively use Ampere-Maxwell’s (1a) and Faraday-Maxwell’s (1b) laws: We take the scalar products of (1a) with \( \mathbf{E} \), and (1b) with \( \mathbf{B} \) that result in

\[
\mathbf{E}(x', t) \cdot \partial_t \mathbf{E}(x', t) = c \mathbf{E}(x', t) \cdot [\nabla \times \mathbf{B}(x', t)] - \\
-4\pi \mathbf{E}(x', t) \cdot \partial_t \mathbf{P}(x', t) - 4\pi \mathbf{E}(x', t) \cdot \mathbf{J}(x', t),
\]

\[
\mathbf{B}(x', t) \cdot \partial_t \mathbf{B}(x', t) = -c \mathbf{B}(x', t) \cdot [\nabla \times \mathbf{E}(x', t)].
\]

Noticing that in the LHSs \( \mathbf{E}(x', t) \cdot \partial_t \mathbf{E}(x', t) = \partial_t \mathbf{E}^2(x', t)/2 \) and \( \mathbf{B}(x', t) \cdot \partial_t \mathbf{B}(x', t) = \partial_t \mathbf{B}^2(x', t)/2 \), so that we obtain after integration over \( (0, T) \times \Omega \):

\[
\begin{align*}
\int_0^T \int_{\Omega} \mathbf{E}(x', t) \cdot \partial_t \mathbf{E}(x', t) d\mathbf{x}' dt &= \frac{1}{2} (\|\mathbf{E}(\cdot, T)\|_{L^2(\Omega)}^2 - \|\mathbf{E}_0(\cdot)\|_{L^2(\Omega)}^2), \\
\int_0^T \int_{\Omega} \mathbf{B}(x', t) \cdot \partial_t \mathbf{B}(x', t) d\mathbf{x}' dt &= \frac{1}{2} (\|\mathbf{B}(\cdot, T)\|_{L^2(\Omega)}^2 - \|\mathbf{B}_0(\cdot)\|_{L^2(\Omega)}^2).
\end{align*}
\]
We add the expressions (29) using that \( \nabla \cdot [E \times B] = B \cdot [\nabla \times E] - E \cdot [\nabla \times B] \), and integrating over \((0, T) \times \Omega \). Finally, using the divergence theorem, we deduce (27).

Now we apply the operator \( \nabla \) to both sides of (1a). Since the divergence of the curl is 0, we obtain the equation

\[
\partial_t \nabla \cdot E(x', t) = -4\pi \partial_t \nabla \cdot P(x', t) - 4\pi \nabla \cdot J(x', t).
\]

We take the product of the scalar equation (30) with a scalar \( \nabla \cdot E \) and again integrate over \((0, T) \times \Omega \) resulting in (28).

**Lemma 3.8.** Suppose that \( E(t)|_{\partial \Omega} = B(t)|_{\partial \Omega} = 0 \in \mathbb{R}^3 \), then for all \( T > 0 \) and \( \Omega \subset \mathbb{R}^3 \)

\[
\begin{align*}
&\|\partial_t E(\cdot, T)\|_{L^2(\Omega)}^3 + c^2\|\nabla \times E(\cdot, T)\|_{L^2(\Omega)}^2 = \|\partial_t E_0(\cdot)\|_{L^2(\Omega)}^3 + \|\nabla \times E_0(\cdot)\|_{L^2(\Omega)}^2 + \|\nabla \times E_0(\cdot)\|_{L^2(\Omega)}^2 \times 8\pi T > 0,
&\|\partial_t B(\cdot, T)\|_{L^2(\Omega)}^3 + c^2\|\nabla \times B(\cdot, T)\|_{L^2(\Omega)}^2 = \|\partial_t B_0(\cdot)\|_{L^2(\Omega)}^3 + \|\nabla \times B_0(\cdot)\|_{L^2(\Omega)}^2 + \|\nabla \times B_0(\cdot)\|_{L^2(\Omega)}^2 \times 8\pi T > 0.
\end{align*}
\]

**Proof.** We differentiate (1a) in time and then multiply both sides by \( \partial_t E \). We note that

\[
\partial_t E \cdot \partial_t^2 E = \frac{1}{2} \partial_t (\partial_t E \cdot \partial_t E) = \frac{1}{2} \partial_t^2 |\partial_t E|^2,
\]

\[
\partial_t E \cdot [\nabla \times [\nabla \times E]] = \nabla \cdot ([\nabla \times E] \cdot \partial_t E) + [\nabla \times E] \cdot [\nabla \times \partial_t E] = \nabla \cdot ([\nabla \times E] \times \partial_t E) + \frac{1}{2} \partial_t |\nabla \times E|^2.
\]

We integrate the equation over \((0, T) \times \Omega \), apply the divergence theorem and obtain (31). Similarly, by differentiation (1b) in time, then by multiplication by \( \partial_t B \) and finally by integration over \((0, T) \times \Omega \) we come to (32).

**Lemma 3.9.** For all \( T > 0 \),

\[
\begin{align*}
&\|J(\cdot, T)\|_{L^2(\Omega)}^3 = \|J_0(\cdot)\|_{L^2(\Omega)}^3 - 2\nu e \int_0^T \|J(\cdot, t)\|_{L^2(\Omega)}^3 dt + \int_0^T \int_\Omega N_e(x', t) J(x', t) \cdot E(x', t) dx' dt +
\end{align*}
\]

and

\[
\begin{align*}
&\|\partial_t J(\cdot, T)\|_{L^2(\Omega)}^3 = \|\partial_t J_0(\cdot)\|_{L^2(\Omega)}^3 - 2\nu e \int_0^T \|\partial_t J(\cdot, t)\|_{L^2(\Omega)}^3 dt + \int_0^T \int_\Omega N_e(x', t) \partial_t J(x', t) \cdot \partial_t E(x', t) dx' dt +
\end{align*}
\]
and

\[ \| \nabla \cdot \mathbf{J}(\cdot, T) \|_{L^2(\Omega)}^2 = \| \nabla \cdot \mathbf{J}_0(\cdot) \|_{L^2(\Omega)}^2 - 2 \nu_e \int_0^T \| (\nabla \cdot \mathbf{J})(\cdot, t) \|_{L^2(\Omega)}^2 dt + \]

\[ + 2 \int_0^T \int_{\Omega} \nabla \mathcal{N}_e(x', t) \cdot \mathbf{E}(x', t) \nabla \cdot \mathbf{J}(x', t) dx' dt + \]

\[ + 2 \int_0^T \int_{\Omega} \mathcal{N}_e(x', t) \nabla \cdot \mathbf{E}(x', t) \nabla \cdot \mathbf{J}(x', t) dx' dt \]

and finally

\[ \| \nabla \times \mathbf{J}(\cdot, T) \|_{(L^2(\Omega))^3}^2 = \| \nabla \times \mathbf{J}_0(\cdot) \|_{(L^2(\Omega))^3}^2 - 2 \nu_e \int_0^T \| (\nabla \times \mathbf{J})(\cdot, t) \|_{(L^2(\Omega))^3}^2 dt + \]

\[ + 2 \int_0^T \int_{\Omega} \nabla \mathcal{N}_e(x', t) \times \mathbf{E}(x', t) \cdot [\nabla \times \mathbf{J}(x', t)] dx' dt + \]

\[ + 2 \int_0^T \int_{\Omega} \mathcal{N}_e(x', t) [\nabla \times \mathbf{E}(x', t)] \cdot [\nabla \times \mathbf{J}(x', t)] dx' dt. \]

**Proof.** We take the scalar product of (5) with \( \mathbf{J} \)

\[ \frac{1}{2} \partial_t |\mathbf{J}(x', t)|^2 = -\nu_e |\mathbf{J}(x', t)|^2 + \mathcal{N}_e(x', t) \mathbf{J}(x', t) \cdot \mathbf{E}(x', t). \]

Integrating over \((0, T)\), gives (33). To prove (34), we differentiate Equation (5) in time, then we take the scalar product of both parts with \( \partial_t \mathbf{J} \), and integrate over \((0, T)\).

By applying \( \nabla \cdot \) on (5), and then integrating over \((0, T)\) with \( \nabla \cdot \mathbf{J} \), we deduce (35). Finally, by applying \( \nabla \times \) on (5), and then integrating over \((0, T)\) with \( \nabla \times \mathbf{J} \), we deduce (36).

**Remark 3.10.** With a view of proper management of the physical variable dimensions in the following lemmas, we should make a remark. Recall that we use atomic units for all the equations, so that from MEs (1a) and (1b) we can conclude that \( \dim(\mathbf{E}) = T \dim(\mathbf{J}) \), where \( T \) is the symbol for the time dimension. Taking into account Drude’s model (5), we can see that \( \dim(\mathcal{N}_e) = T^{-2} \). In the following, we introduce a constant \( \eta > 0 \), having the dimension of time, \( \dim(\eta) = T \).

**Lemma 3.11.** There exists a constant \( C > 0 \) such that for all time \( T > 0 \)

\[ \sup_{0 \leq t \leq T} \| \mathbf{E}(\cdot, t) \|_{H^1(\Omega)}^3 + \sup_{0 \leq t \leq T} \| \mathbf{B}(\cdot, t) \|_{H^1(\Omega)}^3 + \eta^2 \sup_{0 \leq t \leq T} \| \mathbf{J}(\cdot, t) \|_{H^1(\Omega)}^3 \leq C. \]

**Proof.** From the result (27) of Lemma 3.7 we have for all \( t \in (0, T] \)

\[ \| \mathbf{E}(\cdot, T) \|_{(L^2(\Omega))^3}^3 + \| \mathbf{B}(\cdot, T) \|_{(L^2(\Omega))^3}^3 \leq \| \mathbf{E}_0(\cdot) \|_{(L^2(\Omega))^3}^3 + \| \mathbf{B}_0(\cdot) \|_{(L^2(\Omega))^3}^3 + \]

\[ + 8\pi \int_0^T \int_{\Omega} |\mathbf{E}(x', t) \cdot \partial_t \mathbf{P}(x', t)| dx' dt + 8\pi \int_0^T \int_{\Omega} |\mathbf{E}(x', t) \cdot \mathbf{J}(x', t)| dx' dt \leq \]

\[ \leq \| \mathbf{E}_0(\cdot) \|_{(L^2(\Omega))^3}^3 + \| \mathbf{B}_0(\cdot) \|_{(L^2(\Omega))^3}^3 + 8\pi \eta^{-1} \int_0^T \| \mathbf{E}(\cdot, t) \|_{(L^2(\Omega))^3}^3 dt + \]

\[ + 4\pi \eta \int_0^T \| \partial_t \mathbf{P}(\cdot, t) \|_{(L^2(\Omega))^3}^3 dt + 4\pi \eta \int_0^T \| \mathbf{J}(\cdot, t) \|_{(L^2(\Omega))^3}^3 dt. \]
Similarly from (28):

\[
\|\nabla \cdot (\cdot, T)\|_{L^2(\Omega)}^2 \leq \|\nabla \cdot E_0(\cdot)\|_{L^2(\Omega)}^2 + 8\pi \int_0^T \int_\Omega |\nabla \cdot E(x', t) \partial_t \nabla \cdot P(x', t)| dx'dt +
+ 8\pi \int_0^T \int_\Omega |\nabla \cdot E(x', t) \nabla \cdot J(x', t)| dx'dt \leq \|\nabla \cdot E_0(\cdot)\|_{L^2(\Omega)}^2 +
+ 8\pi \eta^{-1} \int_0^T \|\nabla \cdot E(\cdot, t)\|_{L^2(\Omega)}^2 dt + 4\pi \eta \int_0^T \|\partial_t \nabla \cdot P(\cdot, t)\|_{L^2(\Omega)}^2 dt +
+ 4\pi \eta \int_0^T \|\nabla \cdot J(\cdot, t)\|_{L^2(\Omega)}^2 dt.
\]

From Lemma 3.6 and (33) of Lemma 3.9, we have for all \( t \in (0, T] \)

\[
\|J(\cdot, T)\|_{L^2(\Omega)}^3 \leq \|J(\cdot)\|_{L^2(\Omega)}^3 + 2\nu_e \int_0^T \|J(\cdot, t)\|_{L^2(\Omega)}^2 \|\nabla \cdot J(x', t)\| dx'dt +
+ 2 \int_0^T \int_\Omega N_e(x', t) |J(x', t) \cdot E(x', t)| dx'dt \leq \|J(\cdot, T)\|_{L^2(\Omega)}^3 +
+ (2\nu_e + \eta^{-1}) \int_0^T \|J(\cdot, t)\|_{L^2(\Omega)}^2 \|\nabla \cdot J(\cdot, t)\|_{L^2(\Omega)}^2 dt + \eta \sup_{\Omega, [0, T]} N_e^2(x', t) \int_0^T \|\nabla \cdot E(\cdot, t)\|_{L^2(\Omega)}^2 dx'dt,
\]

and with Lemma 3.6 and (35)

\[
\|\nabla \cdot J(\cdot, T)\|_{L^2(\Omega)}^2 \leq \|\nabla \cdot J(\cdot)\|_{L^2(\Omega)}^2 + 2\nu_e \int_0^T \int_\Omega |(\nabla \cdot J(x', t))|^2 dx'dt +
+ 2 \int_0^T \int_\Omega N_e(x', t) \cdot E(x', t) \nabla \cdot J(x', t)| dx'dt +
+ 2 \int_0^T \int_\Omega |N_e(x', t) \nabla \cdot E(x', t) \nabla \cdot J(x', t)| dx'dt \leq \|\nabla \cdot J(\cdot, T)\|_{L^2(\Omega)}^2 +
+ 2(\nu_e + \eta^{-1}) \int_0^T \|\nabla \cdot J(\cdot, t)\|_{L^2(\Omega)}^2 dt +
+ \eta \sup_{\Omega, [0, T]} (\nabla N_e(x', t))^2 \int_0^T \|\nabla \cdot E(\cdot, t)\|_{L^2(\Omega)}^2 dx'dt +
+ \eta \sup_{\Omega, [0, T]} N_e^2(x', t) \int_0^T \|\nabla \cdot E(\cdot, t)\|_{L^2(\Omega)}^2 dx'dt.
\]

Combining the first and third inequalities, we get:

\[
\|E(\cdot, T)\|_{L^2(\Omega)}^3 + \|B(\cdot, T)\|_{L^2(\Omega)}^3 \leq \|E_0(\cdot)\|_{L^2(\Omega)}^3 + \|B_0(\cdot)\|_{L^2(\Omega)}^3 + \|J(\cdot, T)\|_{L^2(\Omega)}^3 +
\leq \|E_0(\cdot)\|_{L^2(\Omega)}^3 + \|B_0(\cdot)\|_{L^2(\Omega)}^3 + \|J(\cdot)\|_{L^2(\Omega)}^3 +
+ (8\pi \eta^{-1} + \eta^3 \sup_{\Omega, [0, T]} N_e^2(x', t)) \int_0^T \|E(\cdot, t)\|_{L^2(\Omega)}^3 dt +
\]

\[
+ (4\pi \eta + 2\nu_e \eta^2 + \eta) \int_0^T \|J(\cdot, t)\|_{L^2(\Omega)}^3 dt + 4\pi \eta \int_0^T \|\partial_t P(\cdot, t)\|_{L^2(\Omega)}^3 dt.
\]

\[\text{(38)}\]
Identically, for the second and fourth inequalities:
\begin{equation}
\|\nabla \cdot E(\cdot, T)\|_{L^2(\Omega)}^2 \leq \|\nabla \cdot E_0(\cdot)\|_{L^2(\Omega)}^2 + \eta^2 \|\nabla \cdot J_0(\cdot)\|_{L^2(\Omega)}^2 + \\
+ (36 \pi \eta^{-1} + \eta^3 \sup_{\Omega, [0, T]} N_2^2(\cdot', t)) \int_0^T \|\nabla \cdot E(\cdot, t)\|_{L^2(\Omega)}^2 dt + \\
+ (4 \pi \eta + 2 \nu c \eta^2 + 2 \eta) \int_0^T \|\nabla \cdot J(\cdot, t)\|_{L^2(\Omega)}^2 dt + \\
+ \eta^3 \sup_{\Omega, [0, T]} (\nabla N_1(\cdot', t))^2 \int_0^T \|E(\cdot, t)\|_{L^2(\Omega)}^2 dt + 4 \pi \eta \int_0^T \|\partial_x \nabla \cdot P(\cdot, t)\|_{L^2(\Omega)}^2 dt.
\end{equation}

In addition to (39), we recall that \(\nabla \cdot B(\cdot', t) \equiv 0\). According to Lemmas 3.5 and 3.6, \(\partial_x P \in L^\infty(0, T; C_0^3)\) and \(N_2(\cdot', t) \in L^\infty(0, T; C_0^3)\), so using Grönwall’s inequality we can confirm boundedness of the norms in the LHS of inequalities (38) and (39). Similarly, using Lemma 3.8 and equations (34) and (36), we can conclude boundedness of the following combination of the norms:
\begin{equation}
\|\partial_t E(\cdot, T)\|_{L^2(\Omega)}^2 + c^2 \|\nabla \times E(\cdot, T)\|_{L^2(\Omega)}^2 + \|\partial_t B(\cdot, T)\|_{L^2(\Omega)}^2 + \\
c^2 \|\nabla \times B(\cdot, T)\|_{L^2(\Omega)}^2 + \nu^2 \left(\|\partial_t J(\cdot, T)\|_{L^2(\Omega)}^2 + c^2 \|\nabla \times J(\cdot, T)\|_{L^2(\Omega)}^2\right).
\end{equation}

From here we deduce (37).}

\textbf{Proof.} of Theorem 3.1. So far, we have proven that for all \(T > 0\), there exists a constant \(C > 0\) such that:
\begin{equation}
\|E\|_{L^\infty(0, T; H^1(\Omega))^3} + \|B\|_{L^\infty(0, T; L^3(\Omega))^3} + \\
\eta^2 \|J\|_{L^\infty(0, T; L^3(\Omega))^3} + \mu \|\psi\|_{L^\infty(0, T; H^1(\Omega))^m} \leq C,
\end{equation}

where \(\mu > 0\) is a dimensional constant, such that \(\dim(\mu) = \dim(E^2)\). The boundness of the last term in the above inequality is a consequence of Lemma 3.2. Now as \(L^\infty(0, T; H^1(\Omega)^3) \times L^\infty(0, T; H^1(\Omega)^m)\) is compactly embedded in \(L^2(0 \times (0, T) \times (L^2(\mathbb{R}^3))^m)\) by Leray-Schauder’s fixed point theorem, we deduce the existence of a solution for (1a), (1b), (2b), and (5). The approach is the same as described in [49]. It is based on the introduction of a continuous mapping derived from (1a), (1b), and (2b), which depends on a parameter \(\lambda \in [0, 1]\) and admits a fixed point in \(L^2(0 \times (0, T) \times (L^2(\mathbb{R}^3))^m)\) as verifying Leray-Schauder’s theorem assumptions [33].

\textit{Uniqueness} is proven by a classical process of introducing two solutions of the Cauchy problem (1a), (1b), and (2b): \((E_1, B_1, J_1, \psi_1)^T\) and \((E_2, B_2, J_2, \psi_2)^T\), and denoting their difference as \((E, B, J, \psi)^T := (E_2 - E_1, B_2 - B_1, J_2 - J_1, \psi_2 - \psi_1)^T\) with ICs \((E(\cdot, 0), B(\cdot, 0), J(\cdot, 0), \psi(\cdot, 0))^T = (0, 0, 0, 0)^T\). As in Lemmas 3.2 and 3.7, see also for details [28], there exists a constant \(C > 0\) such that:

\begin{equation}
\frac{d}{dt} \left\{ \frac{\mu \|\psi(t)\|_{H^1(\Omega)^m}^2}{H^1(\Omega)^m} + \int_\Omega (\|E(x, t)\|_{L^2(\Omega)}^2 + \\
+ \|B(x, t)\|_{L^2(\Omega)}^2 + \eta^2 \|J(x, t)\|_{L^2(\Omega)}^2) dx \right\} \leq \\
C \left\{ \frac{\mu \|\psi(t)\|_{H^1(\Omega)^m}^2}{H^1(\Omega)^m} + \int_\Omega (\|E(x, t)\|_{L^2(\Omega)}^2 + \\
+ \|B(x, t)\|_{L^2(\Omega)}^2 + \eta^2 \|J(x, t)\|_{L^2(\Omega)}^2) dx \right\}.
\end{equation}
Using Grönwall’s inequality we conclude \((E(\cdot,t), B(\cdot,t), J(\cdot,t), \bar{\psi}(\cdot,t))^T \equiv (0, 0, 0, 0)^T\) for all \(t > 0\). Moreover, the polarization is also unique, \(P = P_2 - P_1 \equiv 0\) for \(t \geq 0\), as by definition:

\[
P(x', t) = N(x') \sum_{i=1}^{m} P_i(x', t) =
N(x') \sum_{i=1}^{m} \chi_{\Omega_i}(x') \int_{\mathbb{R}^3 \times \mathbb{R}_+} x(\psi_{i,1}(R_0, x, t))^2 - |\psi_{i,2}(R_0, x, t)|^2) \, dx \, dR_0,
\]

and as \(\bar{\psi}(\cdot, t) \equiv 0\) for all \(t > 0\).

The main practical consequence of Theorem 3.1 in the sense of numerical treatment of the model is the conservation in time of regularity of the solutions, which justifies the use of finite difference methods (FDM) for solving equations formed the MASP model [27, 28]. In addition, we note that the FDM is a natural choice as the geometry of the computational domains of the MEs and TDSEs are simple enough.

### 3.2. MASP Model Supplemented by Evolution Equations for Polarization and Free Electron Density.

This part discusses the issue, whether we could still rely on the same regularity of solutions in case of the MASP model enriched by the evolution equations for polarization and free electrons density. Certainly, it is too complicated to prove the theorem of existence and uniqueness for the MASP model with embedded general evolution equation (21) which, moreover, is nonlinear. However, since we intend to use this equation in the regime of relatively weak nonlinearity (with purpose to obtain a correction to the solution of homogeneous equation), it makes sense to consider at least the MASP model complemented by the homogeneous wave equations for polarization vector:

\[
\partial_t^2 P - v_g^2 \Delta P = 0,
\]

with velocity \(v_g\), considered as a constant. Note that if we apply the operator \(\nabla\) to both sides of (41) and recall that the divergence of the polarization vector equals to the density of the bound charges taken with opposite sign, \(\nabla \cdot P = -(\mathcal{N} - \mathcal{N}_e)\), we obtain the evolution equation for the free electron density:

\[
\partial_t^2 \mathcal{N}_e - v_g^2 \Delta \mathcal{N}_e = 0,
\]

while the afore-mentioned equation (17) describes one-directional wave only. To obtain (42), we recall that the gas density depends on spatial coordinate only, \(N = N(x')\), and we make an assumption that this dependence is close to constant, i.e. \(\nabla N(x') = 0\) and \(\Delta N(x') = 0\) for all \(x' \in \Omega\).

We intend to solve the system of equations (1a), (1b), (2b), (5), (41), and (42) subject to the initial data set \((E_0, B_0, J_0, \psi_0, P_0, \partial_t P_0, \mathcal{N}_e, \partial_t \mathcal{N}_e)^T\). For simplicity, we assume that the bounded domain of Maxwell’s equations \(\Omega\) contains only one “subdomain” \(\bar{\Omega}\) with a gas, which means that now \(v_0 \equiv v_0, 1\). Using these microscopic data, we can compute \(P(t)|_{\Omega_0}\), see (2a), and \(\mathcal{N}(t)|_{\partial \Omega_0}\) see (6), (7), and their time derivatives in the first cell of the gas region, i.e. on the boundary of the gas region. We suppose that initially within the domain, the polarization vector and free electron number density equal zero: \(P_0 = 0 \in \mathbb{R}^3, \partial_t P_0 = 0 \in \mathbb{R}^3, \mathcal{N}_e = 0 \in \mathbb{R}, \partial_t \mathcal{N}_e = 0 \in \mathbb{R}\). This provides for wave equations (41) and (42) the initial-boundary value problems. Now we state the existence theorem for the supplemented MASP model.
THEOREM 3.12. Suppose that \((E_0, B_0, J_0) \in (H^1(\Omega))^3 \times (H^1(\Omega))^3 \times (H^1(\Omega))^3\), \(\psi_0 \in (H^1 \cap H_1)\), \(R_0 > 0\) is a constant for all \(t \in \mathbb{R}_+\) and \(N \in C_0^\infty(\Omega)\). Suppose that on the smooth boundary \(\partial \Omega\) zero Dirichlet BCs are imposed for vectors \(E, B, J, P\) for all \(t \in \mathbb{R}_+\). In addition, on the smooth boundary \(\partial \Omega\) of the gas region the values of \(P(t)|_{\partial \Omega} \cdot N_c(t)|_{\partial \Omega}\) are computed via \(\psi(R_0, x, t)\) from (2b), (6), and (7) with \(m = 1\), while for \(t = 0\) \((P_0, \partial_t P_0, N_{c0}, \partial_t N_{c0}) = (0, 0, 0, 0)\). Then there exists a time \(T > 0\), and a unique solution \((E, B, J, P, \psi) \in (L^\infty(0, T; (H^1(\Omega))^3) \cap H^1(0, T; (L^2(\Omega))^3))^4 \times L^\infty(0, T; (H^1 \cap H_1))\) to Equations (1a), (1b), and (2b) (with \(m = 1\), (5), (41), and (42).

In the case of the MASP model supplemented by the evolution equations (41) and (42), we first need to adjust several lemmas proven above. In particular, Lemmas 3.4 and 3.5 are still true for \(x' = x'_1\), i.e. in the first gas “cell” only. However, inside the gas subdomain we have to consider the evolution equations, in particular

\[
\partial_t^2 P = v_g^2 \Delta P.
\]

**Lemma 3.13.** We assume Dirichlet BCs on \(\partial \Omega\): \(P(t)|_{\partial \Omega} = 0 \in \mathbb{R}^3\), then for all \(T > 0\), and \(\Omega \subset \mathbb{R}^3\)

\[
\begin{align*}
\|\partial_t P(\cdot, T)\|_{L^2(\Omega)}^2 + v_g^2 \|\nabla \times P(\cdot, T)\|_{L^2(\Omega)}^2 &= \|\partial_{\Omega} P(\cdot)\|_{L^2(\Omega)}^2 + 2v_g^2 \int_0^T \int_{\Omega} \partial_t (\partial_t P(\cdot, t) \cdot \nabla N_c(\cdot, t)) dx dt.
\end{align*}
\]

**Proof.** We multiply (43) by \(\partial_t P\) and consider separately the LHS and the RHS:

\[
\begin{align*}
\partial_t P \cdot \partial_t^2 P &= \frac{1}{2} \partial_t |\partial_t P|^2, \\
\partial_t P \cdot \triangle P &= (\partial_t P \cdot \nabla)(\nabla \cdot P) - \partial_t P \cdot [\nabla \times [\nabla \times P]],
\end{align*}
\]

where \(|\partial_t P|^2 = \partial_t P \cdot \partial_t P\).

Recall that \(\nabla \cdot P = -(N - N_c)\), so the first term of the RHS reads

\[
(\partial_t P \cdot \nabla)(\nabla \cdot P) = -(\partial_t P \cdot \nabla)(N - N_c) = \partial_t P \cdot \nabla N_c.
\]

The second term in (46) can be rewritten

\[
\partial_t P \cdot [\nabla \times [\nabla \times P]] = \nabla \cdot [\nabla \times P] \times \partial_t P + [\nabla \times P] \cdot [\nabla \times \partial_t P] = \\
\nabla \cdot [\nabla \times P] \times \partial_t P + \frac{1}{2} \partial_t |\nabla \times P|^2,
\]

so finally we come to

\[
\partial_t \{ |\partial_t P|^2 + v_g^2 |\nabla \times P|^2 \} = 2v_g^2 \partial_t P \cdot \nabla N_c - 2v_g^2 \nabla \cdot [\nabla \times P] \times \partial_t P.
\]

Now we integrate (47) over \((0, T) \times \Omega\) (applying the divergence theorem and using the BCs) to obtain (44). \(\square\)

Similarly, in addition to Lemma 3.6 we need to consider the property of \(N_c\) inside the subdomain.

**Lemma 3.14.** We assume Dirichlet BCs on \(\partial \Omega\): \(N_c(t)|_{\partial \Omega} = 0 \in \mathbb{R}\), then for all \(T > 0\) and \(\Omega \subset \mathbb{R}^3\)

\[
\begin{align*}
\|\partial_t N_c(\cdot, T)\|_{L^2(\Omega)}^2 + v_g^2 \|\nabla N_c(\cdot, T)\|_{L^2(\Omega)}^2 &= \|\partial_t N_c(\cdot)\|_{L^2(\Omega)}^2 + v_g^2 \|\nabla N_c(\cdot)\|_{L^2(\Omega)}^2.
\end{align*}
\]
Lemma 3.11 are satisfied. Now we can extend we deduce boundedness of \( \xi \in C_T \). Then by Lemma 3.15 and for all \( \xi \in C_T \). In the case of the enriched MASP model.

\[
\sup_{0 \leq t \leq T} \| \xi(t) \|_{H^1(\Omega)} \leq C_1.
\]

Proof. From \( \partial_t \xi^2 = 2N_\partial_t N_\xi \) we deduce

\[
\| \xi(t) \|_{L^2(\Omega)}^2 \leq \| \xi_0 \|_{L^2(\Omega)}^2 + \eta^{-1} \int_0^T \| \xi(t) \|_{L^2(\Omega)}^2 dt + \eta \int_0^T \| \partial_t \xi(t) \|_{L^2(\Omega)}^2 dt.
\]

From now on in current section, \( \eta \) is defined in the same way as in Remark 3.10. Then from (48) and (52) and Grönwall’s inequality we come to (51).

Lemma 3.16. There exists a constant \( C_2 \) > 0 such that for all \( T > 0 \)

\[
\sup_{0 \leq t \leq T} \| P(t) \|_{H^1(\Omega)^3} \leq C_2.
\]

Proof. From Lemma 3.13 and for all \( t > 0 \)

\[
\| \partial_t P(t) \|_{L^2(\Omega)}^3 + \eta \| \nabla \times P(t) \|_{L^2(\Omega)}^3 + \eta^{-1} \int_0^T \| \partial_t P(t) \|_{L^2(\Omega)}^3 dt + \eta \int_0^T \| \partial_t \xi(t) \|_{L^2(\Omega)}^3 dt.
\]

Thus, we can conclude by Grönwall’s inequality and (51) that \( \| \partial_t P(t) \|_{L^2(\Omega)}^3 \) and \( \| \nabla \times P(t) \|_{L^2(\Omega)}^3 \) are bounded. We recall that according Lemma 3.15 and relation \( \nabla \cdot P = -\langle N_\partial N_\xi \rangle \), norm \( \| \nabla \cdot P(t) \|_{L^2(\Omega)}^3 \) is bounded as well. Hence from \( \partial_t P^2 = \xi \partial_t P \) we obtain

\[
\| P(t) \|_{L^2(\Omega)}^3 \leq \| P_0 \|_{L^2(\Omega)}^3 + \eta^{-1} \int_0^T \| P(t) \|_{L^2(\Omega)}^3 dt + \eta \int_0^T \| \partial_t \xi(t) \|_{L^2(\Omega)}^3 dt,
\]

thus, again with Grönwall’s inequality and (54) we deduce (53).

Note that from Lemma 3.15 we deduce boundedness of \( \| \partial_t (\nabla \cdot P)(t) \|_{L^2(\Omega)}^3 = \| \partial_t \xi(t) \|_{L^2(\Omega)}^3 \) and then deduce (53). That means, all needed conditions to prove Lemma 3.11 are satisfied. Now we can extend Lemma 3.11 in the case of the enriched MASP model.
LEMMA 3.17. There exists a constant $C > 0$ such that for all $T > 0$

$$\sup_{0 \leq t \leq T} \|E(t)\|_{L^2}^2 + \sup_{0 \leq t \leq T} \|B(t)\|_{L^2}^2 + \eta^2 \sup_{0 \leq t \leq T} \|J(t)\|_{L^2}^2 + \sup_{0 \leq t \leq T} \|P(t)\|_{L^2}^2 \leq C.$$  

(55)

Proof. We can deduce this result from Lemma 3.11 and Lemma 3.16.

Proof of Theorem 3.12. As in the proof of Theorem 3.1, the existence is based on Leray-Schauder’s fixed point theorem [33]. In Lemmas 3.2 to 3.9 and 3.11 and Lemmas 3.13 to 3.16, we proved that for all $T > 0$ there exists a constant $C > 0$ such that:

$$\|E\|_{L^2(0,T;H^1(\Omega)^3)} + \|B\|_{L^2(0,T;H^1(\Omega)^3)} + \eta^2 \|J\|_{L^2(0,T;H^1(\Omega)^3)} + \|P\|_{L^2(0,T;H^1(\Omega)^3)} + \mu \|\psi\|_{L^2(0,T;H^1(\Omega)^3)} \leq C,$$

and $L^\infty(0,T;H^1(\Omega)^3) \times L^\infty(0,T;H^1(\Omega)^3) \times L^\infty(0,T;H^1(\Omega)^3)$ is compactly embedded in $L^2(\Omega \times (0,T)) \times (L^2(\mathbb{R}^3 \times \mathbb{R}^3))$. The approach follows [49]. We introduce a continuous mapping derived from (1a), (1b), (2b), (5), (41), and (42), that depends on a parameter $\lambda \in [0,1]$ and that admits a fixed point in $L^2(\Omega \times (0,T]) \times (L^2(\mathbb{R}^3 \times \mathbb{R}^3))$ as verifying Leray-Schauder’s theorem assumptions.

To prove uniqueness, we take the difference vector $(E, B, J, P, \bar{\psi})^T := (E_2 - E_1, B_2 - B_1, J_2 - J_1, P_2 - P_1, \bar{\psi}_2 - \bar{\psi}_1)^T$, with zero ICs, where $(E_1, B_1, J_1, P_1, \bar{\psi}_1)^T$ and $(E_2, B_2, J_2, P_2, \bar{\psi}_2)^T$ denote two solutions. Then applying the methods presented in the above lemmas, see also [28], we come to the inequality with some constant $C > 0$:

$$\frac{d}{dt} \left( \mu \|\bar{\psi}(t)\|_{H^1(\Omega)^3}^2 + \int_\Omega \left( \|E(x', t)\|_{L^2(\Omega)}^2 + \|B(x', t)\|_{L^2(\Omega)}^2 \right) dx' \right) + \eta^2 \|J(x', t)\|_{L^2(\Omega)}^2 + \mu \|\psi(t)\|_{H^1(\Omega)^3}^2 + \|P(x', t)\|_{L^2(\Omega)}^2 \right) dx' \right) \leq$$

$$C \left\{ \mu \|\bar{\psi}(t)\|_{H^1(\Omega)^3}^2 + \int_\Omega \left( \|E(x', t)\|_{L^2(\Omega)}^2 + \|B(x', t)\|_{L^2(\Omega)}^2 \right) dx' \right\}.$$

(56)

We conclude by Grönwall’s inequality that $(E(\cdot, t), B(\cdot, t), J(\cdot, t), P(\cdot, t), \bar{\psi}(\cdot, t))^T \equiv (0, 0, 0, 0)^T$ for all $t > 0$.

Summarizing the outcomes of this part, because of the regularity of the solutions not only of the “pure” MASP model, but the “extended” MASP model as well.

4. Numerical Methods and Parallel Computing. For 1d Maxwell’s equations we use the second order Lax-Wendroff scheme, see e.g. [46], which is stable under the Courant-Friedrichs-Lewy (CFL)-condition. We solve the 2d Schrödinger equation in 3 stages using the symmetric Strang splitting of second order [44]. At the second stage, we solve the equation with static Coulomb potential using Crank-Nicolson’s scheme, which is unconditionally stable. Note that we deal with the multiscale problem, where the time step $\Delta t_S$ for Schrödinger’s equation is much smaller than for Maxwell’s equations $\Delta t_M$: $\frac{\Delta t_M}{\Delta t_S} = 10 \ldots 20$, see also [32]. Finally, to preserve
the second order of convergence of the overall scheme, we use Adams-Bashforth’s second order consistent method to solve Drude’s equation (5) and Lax-Wendroff-type scheme for solving the evolution equation for polarization in its simplest (8) or nonlinear (22) form.

Now we discuss the coupling of the schemes approximating (i) the MASP model, (ii) the polarization evolution equation (15), and (iii) the free electron density evolution equation (17). As an example, we assume that the gas region \( L \), is divided in 4 subdomains each containing \( N_2 \) Maxwell’s cells, see Figure 2. At time \( t^n \) each of 4 processors solves the TDSE only in the first cell of the subdomain assigned to it, i.e. at nodes \( z'_{n,1} \), where \( \alpha = \{1, 2, 3, 4\} \) is the ordinal number of the subdomain, and the second index corresponds to the position number within the subdomain, see Figure 3. Then the data \( \partial P^{n}_{\alpha,1} \) and \( \mathcal{N}^{n}_{\alpha,1} \) are sent to the root processor in order to update (i) the current of free electrons \( J^{n}_{\alpha,\mu} \), and then (ii) the EM field at time \( t^{n*} \): \( \mathbf{E}^{n*}_{\alpha,\mu} \), \( \mathbf{B}^{n*}_{\alpha,\mu} \), \( \mu = 1, \ldots, N_2 \). Note that at this point, we assume that the root processor knows the values of \( \partial P^{n}_{\alpha,\mu} \) and \( \mathcal{N}^{n}_{\alpha,\mu} \) for all spatial points \( z'_{n,\mu} \) (\( \alpha = 1, \ldots, 4 \), \( \mu = 1, \ldots, N_2 \)), but not only for the first cells \( z'_{n,1} \) where the TDSEs are solved. To clarify that apparent contradiction, we point out that at the time \( t \in (t^{n*}, t^{n+1}) \), the root processor evaluates \( \partial P^{n+1}_{\alpha,\mu} \) and \( \mathcal{N}^{n+1}_{\alpha,\mu} \) for the next time cycle, in all Maxwell’s cells using the evolution equations for the polarization and the free electron density. Finally, we generalize the described scheme in the case of \( m \) subdomains and \( l \) processors, requiring the ratio \( m/l \) to be an integer.

5. Numerical Experiments. In this section, we present some results obtained with the enriched MASP model, and compare them with those obtained with the “pure” MASP model.

Fig. 3. Example of parallelization: 1d-2d MASP model enriched by the evolution equations. Index of subdomain \( \alpha = 1 \ldots N_1 \) (here \( N_1 = 4 \)), index of the cell in the subdomain \( \mu = 1 \ldots N_2 \). Length of the gas region \( L = 4 \times N_2 \times \Delta z' \).
5.1. The MASP Model Enriched by the Simple Evolution Equation.

We start by reporting the results of the 1d-2d MS model supplemented by the homogeneous transport equation (8), setting first $v_g = c$. The propagation path of the pulse in the gas region $L$, is divided into $N_1$ subdomains, each containing $N_2$ Maxwell’s cells, see Figure 2. At each Maxwell’s time step, the TDSEs are solved several times (as $\Delta t_M / \Delta t_S \geq 10$) to provide the values of $P$ in the first cells of each subdomain. The polarization in the remaining cells of the subdomains is supposed to be computed from the macroscopic transport equation (8) at the previous time step. The corresponding parallel computing strategy is presented in Figure 3.

We present in Figure 4, the spectral intensity $I(\omega)$ of the linearly polarized pulse, whose field vector $\mathbf{E}$ is parallel to the axis of $\text{H}_2^+$-molecule. The spectral intensity is computed via the Fourier transform of the electric field: $I(\omega) = c|\mathbf{E}(\omega)|^2/8\pi$, as soon as the pulse envelope escapes from the gas region and appears “as a whole” in the last vacuum region. As we see, when the initial intensity is not high, e.g. $I = 5 \times 10^{13}$ W/cm$^2$, the MS model enriched even by the simplest evolution equation provides decent approximations of spectra depending on the chosen partitions of the total number of cells in the gas region $N$ into number of subdomains $N_1$ and number of cells per each subdomain $N_2$ (see the legend).

Within the same approach we also modeled the propagation of the circularly polarized initial pulse. In particular, we report in Figure 5 the intensities of the first generated odd harmonics as functions of the propagation length in the gas. Compar-

![Figure 4](image-url)

**Fig. 4.** Spectral intensities of the electric field harmonics for different gas region lengths; $\lambda = 800$ nm, $I = 5 \times 10^{13}$ W/cm$^2$, $\Delta z_M = 100$ a.u., so that $L = 100 \times N$ a.u. (see the legend for values of $N = N_1 \times N_2$). The grid for solving 2-d TDSE is 300 x 300 with step $\Delta x_S = \Delta y_S = 0.3$ a.u., gas density $N = 5.17 \times 10^{-5}$ a.u.
Fig. 5. Intensity of the low order harmonics of the circularly polarized pulse as a function of the propagation length in a gas: $L = 100 \times N$ ($N = 4, 16, 64, 16 \times 16$ and $32 \times 16$) a.u.; $\lambda = 800$ nm, $I = 5 \times 10^{13}$ W/cm$^2$. The grid for solving 2-d TDSE is $500 \times 500$ with step $\Delta x = \Delta y = 0.3$ a.u., gas density $N = 5.17 \times 10^{-5}$ a.u.

Table 1

| $N_1 \times N_2$ | 64 | 8 x 8 | 256 | 16 x 16 |
|-------------------|----|-------|-----|---------|
| Proc. time (LP) (h:m) | 03:49 | 03:56 | 04:35 | 04:44 |
| Proc. time (CP) (h:m) | – | – | 13:35 | 13:04 |

Processing times for computation of propagation of linearly polarized (LP) and circularly polarized (CP) pulses in the gas, depending on the product of the number of subdomains ($N_1$) and the number of cells per subdomain ($N_2$).
5.2. The MASP Model Enriched by the Nonlinear Evolution Equation. In order to simulate the propagation of pulses with higher initial intensities, we consider the more complicated polarization evolution equation (22). Further, we will compare the transmitted electric fields and spectra computed using the models enriched by the nonlinear and simple polarization equations with the results of the “pure” MS/MAFP models, considering the latter as reference data, see Figure 6. Let us briefly discuss these figures. Note that in our computations we used different intensities of the initial pulse, \( I_1 = 10^{14} \) W/cm\(^2\), \( I_2 = 5 \times 10^{14} \) W/cm\(^2\) and different number densities \( N_{01} = 1.63 \times 10^{-5} \) a.u. and \( N_{02} = 5.17 \times 10^{-5} \) a.u. It is clear that the higher intensity of the pulse and density of the gas, the greater influence of the free electron currents on dynamics of the process. For example, in case of initial pulse with \( I_1 \), \( L^2 \)-norm of the wavefunction is \( \| \psi \|_{L^2} \approx 0.66 \), while in case of \( I_2 \) we obtained \( \| \psi \|_{L^2} \approx 10^{-6} \), which results in significant difference in the free electron number density (18). That is why the computations involving \( I_2 \) were performed with the MASP model. Recall that unlike the MS model, the MASP model takes into account the currents of free electrons.

![Figure 6](image-url)
As we see from Figures 6a and 6b, if we consider pulses with the same initial intensity $I_1$, but propagating in gases of different density, for definiteness $N_{01} < N_{02}$, the amplitude of the transmitted electric field is a bit lower in the case of a higher density, due to stronger ionization losses. However, the generation of the high odd harmonics is more intense for $N_{02}$, see Figure 6b, as the polarization of the medium is proportional to the gas number density. On the other hand, in the case of initial intensity $I_2 > I_1$ the level of ionization becomes much higher (with respect to initial intensity $I_1$). As a result, the amplitudes of the high harmonics are relatively smaller.

Including the instantaneous susceptibility coefficient $\chi^{(3)}$ (or even $\chi^{(5)}, \chi^{(7)}$, and so on) as a parameter in the polarization evolution equation (22), we are pursuing two objectives: to describe more accurately (i) the electromagnetic field profile, and (ii) the spectrum of harmonics. In the following set of figures, we report the data computed within the MASP model supplemented by the evolution equations. We start from the length of the gas region $L = 256 \times 100$ a.u., with propagation time $T = 1051.87$ a.u. We use 3 different values of $\chi^{(3)}$ to test the model. At first glance, even simulations engaging the transport equation with $v_g = c$ and $\chi^{(3)} = 0$, describe the field profile decently; however, as we are comparing the corrections for nonlinear effects accumulating very slowly, we need to pay attention to the very top parts of the electric field profiles, see Figure 7. Then we notice with initial intensity $I_1$, the parameter $\chi^{(3)} = 10^{-4}$ works better for both gas densities. In Figure 8, we also report $\ell_2$ and $\ell_\infty$-norms of the solutions presented in Figure 7b and the errors computed with respect to the “pure” MASP model. As we observe, in all the figures the dashed blue curves corresponding to $\chi^{(3)} = 10^{-4}$ provides the closest agreement with the results of the “pure” MASP model in conformity with results in Figure 7.

Now we proceed to the presentation of the high harmonics spectra, see Figure 9. The simulation parameters for these spectra are exactly the same as for Figure 7. We observe that the selection $\chi^{(3)} = 4 \times 10^{-4}$ a.u. yields less precise results than the two other options. In this case, we are overestimating again the response of the bound electrons. Moreover, the evolution equation (22) with $\chi^{(3)}$ in the RHS, may account corrections to polarization of the 3rd harmonic only, while these computations seems to be adequate even with homogeneous transport equation (8).

The situation changes at higher initial intensities, e.g. $I_2 = 5 \times 10^{14}$ W/cm$^2$ that, as we know, results in significant ionization. In this case, introducing instantaneous nonlinear susceptibility does not seem appropriate. In Figure 10a, we observe the differences between the solutions of the “pure” and “enriched” MASP models. This was expected, as $\chi^{(3)}$ describes the response of bound electrons, whose number is way below the number of free electrons at high intensity. Even so, we still can rely on simulation with the transport equation as it follows from comparison between the heavy black and the thin red curves in Figure 10a.

In Figure 10b we report the high harmonic spectra formed after propagation of the pulse of initial intensity $I_2 = 5 \times 10^{14}$ W/cm$^2$ through the gas. The first three solutions (according to the legend) correspond to the electric field profiles represented in Figure 10. The 4th solution was obtained under the assumption $J = 0$, which as we know is wrong for that intensity. In the large, one can observe the best convergence, inter alia, between solutions of the pure MASP model (heavy black curves on Figures 10a and 10b) and those of the MASP model enriched by the homogeneous transport equation (thin red curves). Just as expected (see the dashed blue curve), adding the perturbative term with $\chi^{(3)}$ to the polarization equation is unsuitable in such ionized gas. We also deduce that including the free electron currents in the model is essential, as the solution in magenta, see Figure 10b, is not a good candidate to fit
Fig. 7. Results of the MASP model supplemented by the polarization evolution equation in comparison with the results of the “pure” MASP model: transmitted electric fields for initial intensity $I_1 = 10^{14}$ W/cm$^2$ and gas number density a) $N_{01} = 1.63 \times 10^{-5}$ a.u., b) $N_{02} = 5.17 \times 10^{-5}$ a.u. Propagation length in gas $L = 256 \times 100$ a.u., which in case of engaging the evolution equation is divided into 4 subdomains each containing 64 cells. Linear instantaneous susceptibility for polarization equation $\chi^{(1)} = 1.83 \times 10^{-5}$, while the coefficient $\chi^{(3)}$ is a model parameter, see the legends.
the “pure” MASP model solution.

Regarding the accurate simulations of the high harmonics spectra within the enriched model, the most important factor (than nonlinearity in the polarization equation) is how Maxwell’s domain is decomposed in subdomains, see Figures 11a and 11b where the propagation length is \( L = 204800 \) a.u. Say, decomposition into 32 subdomains each containing 64 cells, allows us to simulate accurately up to 35 harmonics, while spending less computing resources: 94 h×256 proc vs. 12 h×32 proc. Moreover, if we are interested in the first 11 harmonics only, we can use decomposition 8×256, which takes 12 h×8 proc.

**Fig. 8.** a) \( \ell_2 \)-norms of solutions presented in Figure 7b; b) \( \ell_\infty \)-norms of the same solutions; c) \( \ell_2 \)-norms of errors of these solutions with respect to the MASP model results; d) \( \ell_\infty \)-norms of errors of these solutions with respect to the MASP model results.
Fig. 9. Spectral intensities of high harmonics. The same parameters as for Figures 7a and 7b.
Fig. 10. Results of the MASP model supplemented by the polarization evolution equation in comparison with the results of the “pure” MASP model: (a) transmitted electric fields for initial intensity $I_2 = 5 \times 10^{14} \text{ W/cm}^2$ and gas number density $N_{O_2} = 5.17 \times 10^{-5} \text{ a.u.}$ Path in a gas $L = 256 \times 100$ a.u., divided into 4 subdomains each containing 64 cells, $\chi^{(1)} = 1.83 \times 10^{-5}$, $\chi^{(3)}$ is a model parameter, see the legends; (b) Spectral Intensity for solutions shown in panel (a), additional solution computed in case $J = 0$. 
6. Conclusion. We have derived and studied some extensions of the MASP model [28, 29], allowing for a wider range of application of this generic nonperturbative model. We have demonstrated that including a polarization evolution equation to the MASP model allows for a significant reduction of the overall computational cost of the original model. We found out that the most universal type of this equation is the homogeneous transport equation. More complex nonlinear polarization equations can be useful when the level of ionization is moderate. By contrast, at high intensity (resulting in high level of ionization), the cheapest choice is the homogeneous transport equation, especially for simulating high order harmonic spectra. In this case, it is shown that the current of free electrons must also be included in the model.

**Fig. 11.** Spectra of high harmonics obtained within the “pure” MASP model and using the evolution equation for polarization. The pulse initial intensity $I_1 = 10^{14}$ W/cm$^2$, gas density $N_0 = 1.63 \times 10^{-5}$ a.u., propagation length in a gas $L = 204800$ a.u. (0.01 mm), which is divided into a) 32 subdomains each containing 64 cells and b) 8 subdomains each containing 256 cells.
Acknowledgements. The authors thank Compute Canada for access to high performance computer facilities for our simulations in highly nonlinear optics.
