Abstract: In this paper we prove that the solutions of the isotropic, spatially homogeneous Nordheim equation for bosons with bounded initial data blow up in finite time in the $L^\infty$ norm if the values of the energy and particle density are in the range of values where the corresponding equilibria contain a Dirac mass. We also prove that, in the weak solutions, whose initial data are measures with values of particle and energy densities satisfying the previous condition, a Dirac measure at the origin forms in finite time.

1. Introduction

In this paper we continue the study of the blow-up and condensation properties of the solutions of the homogeneous Nordheim equation initiated in [3]. This system describes the dynamics of a dilute homogeneous quantum gas of bosons. We will denote as $F(t,p)$ the distribution of particles in the momentum space. The evolution of $F$ is given by the following system of equations (cf. [12]):

$$\partial_t F_1 = \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} q(F) M d^3p_2 d^3p_3 d^3p_4, \quad p_1 \in \mathbb{R}^3, \quad t > 0$$  \hspace{1cm} (1.1)

$$F_1(0,p) = F_0(p), \quad p_1 \in \mathbb{R}^3$$  \hspace{1cm} (1.2)

$$q(F) = q_3(F) + q_2(F), \quad \epsilon = |p|^2$$  \hspace{1cm} (1.3)

$$M = \mathcal{M}(p_1, p_2; p_3, p_4) = \delta(p_1 + p_2 - p_3 - p_4) \delta(\epsilon_1 + \epsilon_2 - \epsilon_3 - \epsilon_4)$$  \hspace{1cm} (1.4)

$$q_3(F) = F_3 F_4 (F_1 + F_2) - F_1 F_2 (F_3 + F_4)$$  \hspace{1cm} (1.5)

$$q_2(F) = F_3 F_4 - F_1 F_2,$$  \hspace{1cm} (1.6)

where we use the notation $F_j = F(t, p_j), \quad j \in \mathbb{R}^3$. Notice that, since we consider homogeneous distributions, the density $F$ measures the number of particles per unit of
volume, i.e., the number of particles with moment in the cube \([p, p + d^3 p]\) in a volume \(V\) would be given by \(F(p) V d^3 p\).

In the case of isotropic distributions the system (1.1)–(1.6) can be rewritten in a simpler form. The isotropy of the solutions means that \(F(t, p) = F(t, R p)\) for any \(R \in SO(3), p \in \mathbb{R}^3, t \geq 0\). Then, there exists a function \(f = f(\epsilon, t)\) where \(\epsilon\) is as in (1.3) such that \(f(t, \epsilon) = F(t, p)\) which solves:

\[
\frac{\partial_t f_1}{\sqrt{2}} = \frac{8\pi^2}{\epsilon_1} \int_0^\infty \int_0^\infty q(f) W d\epsilon_3 d\epsilon_4 \tag{1.7}
\]

where:

\[
W = \min \left\{ \frac{\sqrt{\epsilon_1}, \sqrt{\epsilon_2}, \sqrt{\epsilon_3}, \sqrt{\epsilon_4}}{\epsilon_1} \right\}, \quad \epsilon_2 = \epsilon + \epsilon_4 - \epsilon_1 \tag{1.8}
\]

and \(q(\cdot)\) is as in (1.3) with \(\epsilon_2 = \epsilon + \epsilon_4 - \epsilon_1\). More details about this computation as well as additional information about the physics of the Nordheim equation can be found in [3].

A theory of global weak solutions for (1.7), (1.8) has been developed by X. Lu in the papers [9–11]. Uniqueness of the weak solutions for a given initial datum is unknown. On the other hand, the local (in time) existence and uniqueness of mild solutions of (1.7), (1.8) was proved in [3]. These results are recalled in detail in Sect. 2.

A different concept of solution for (1.7) has been introduced in [4,5] where a class of classical solutions of (1.7) which behave as \(f(\epsilon, t) \sim a(t) \epsilon^{-\frac{7}{6}}\) as \(\epsilon \to 0\) has been obtained. Such solutions have a decreasing number of particles with \(\epsilon > 0\).

One of the main interests of the study of (1.1)–(1.6) or its isotropic counterpart (1.7) is the relation of these systems with the dynamical formation of Bose–Einstein condensates (cf. [7,8,13,14]). It can be argued, on physical grounds, that the steady states of (1.1), (1.3)–(1.6) are the Bose–Einstein distributions:

\[
F_{BE}(p) = m_0 \delta(p - p_0) + \frac{1}{\exp \left( \frac{\beta |p-p_0|^2}{2} + \alpha \right) - 1}, \tag{1.9}
\]

where \(m_0 \geq 0, \beta \in (0, \infty], 0 \leq \alpha < \infty\) and \(\alpha m_0 = 0, p_0 \in \mathbb{R}^3\). The precise sense in which the distributions \(F_{BE}\) are steady states requires further clarification, because the right-hand side of (1.1) is not defined in general if \(F\) contains Dirac measures. The main reason to consider the distributions \(F_{BE}\) as the steady states of (1.1), (1.3)–(1.6) is that these distributions maximize the entropy of the system of bosons under consideration for a given value of the momentum, energy and number of particles of the system for unit of volume (cf. (6)). It has been proved in [10] that the weak solutions of (1.7), (1.8) converge, as \(t \to \infty\), to the only equilibrium with the same particle number and energy as their initial data.

One of the most peculiar features of the steady states \(F_{BE}\) in (1.9) is the possible presence of a macroscopic fraction of particles at the value \(p = p_0\). This feature is known as Bose–Einstein condensation. We will assume in the following that the total momentum of the system is zero. This can be always assumed choosing a suitable inertial system. In this case the thermodynamics of the system of bosons can be described by means of two quantities, namely the number of particles by unit of volume \(M\) and the energy for unit of volume \(E\):

\[
M = \int F_{BE}(p) d^3 p, \quad E = \int F_{BE}(p) \frac{|p|^2}{2} d^3 p.
\]
It is possible to associate unique values of \( m_0, \beta \) and \( \alpha \), with \( \alpha \cdot m_0 = 0 \) to any pair of values \( M > 0, E > 0 \). We can split the set of all the values for the particle density and energy \( (M, E) : M > 0, E > 0 \) into two different phases, namely the set of values for which the corresponding value of \( m_0 \) in (1.9) is positive, and those values of \( M, E \) for which \( m_0 = 0 \). We will say that the first class of states has a Bose–Einstein condensate, while the second class of states does not have a condensate. It is not hard to see (cf. Subsect. 3.1) that the set of values \( (M, E) \) for which there is a nontrivial condensate is characterized by:

\[
M > \frac{\zeta \left( \frac{3}{2} \right)}{\left( \frac{4\pi}{3} \right)^{\frac{3}{2}}} E^{\frac{3}{5}},
\]

where \( \zeta (\cdot) \) is the Riemann zeta function.

The theory of Bose–Einstein condensates described above is meaningful for particle systems described by the equilibrium distributions \( F_{BE} \) in (1.9). On the other hand, the Eqs. (1.1)–(1.6) can be used to describe the evolution of a large class of particle distributions \( F_0 \) satisfying some general conditions which ensure that the particle and energy densities remain constant for arbitrary times. It has been suggested in the physical literature (cf. \([7,8,13,14]\)) that the onset of a macroscopic fraction of particles at the lowest energy level (i.e., a condensate) is related to the blow-up at some finite time \( T^* \) of the solutions of (1.1), (1.3)–(1.6). More precisely, the numerical simulations in \([8,13]\) show the existence of isotropic solutions of (1.7), with initial data \( f(0, \epsilon) = f_0(\epsilon) \), that become unbounded in finite time. It has actually been proved in \([3]\) that there exist a large class of bounded initial distributions \( f_0 \) for which the corresponding solutions of (1.7) blow-up in finite time. To wit, a blow-up condition has been obtained which states that for any initial particle distribution with a large concentration of particles with small energy, the corresponding solution of (1.7) becomes unbounded in finite time.

The scenario for the dynamical formation of Bose–Einstein condensates presented in (cf. \([7,8,13,14]\)) suggests that, after this finite time blow up, the measure \( g(t, \epsilon) = 4\pi \sqrt{2}\epsilon f(t, \epsilon) \) contains a Dirac mass at the origin for all later times \( t > T^* \). It was proved in \([3]\) that if the initial data \( g_0 \) satisfies a certain condition, that amounts to having a sufficiently large concentration of particles with small energy, then \( g(t, \epsilon) \) contains a Dirac mass at the origin for all times greater than some finite \( T_{cond} \geq T^* \). It has not been proved that \( T_{cond} = T^* \).

We now define precisely the concept of subcritical and supercritical data. Given a distribution of particles \( f_0 \) we can evaluate the corresponding number of particles and energy respectively by means of:

\[
4\pi \int_0^\infty f_0(\epsilon) \sqrt{2}\epsilon d\epsilon = M, \quad 4\pi \int_0^\infty f_0(\epsilon) \sqrt{2}\epsilon^3 d\epsilon = E.
\]

We will say that \( f_0 \) is supercritical if the inequality (1.10) holds. If, on the contrary, we have \( M < \frac{\zeta \left( \frac{3}{2} \right)}{\left( \frac{4\pi}{3} \right)^{\frac{3}{2}}} E^{\frac{3}{5}} \), we will say that the distribution \( f_0 \) is subcritical.

Notice that given a supercritical distribution, the corresponding stationary distribution having the same amount of particles and energy would have a nontrivial condensate.
We prove in this paper that any solution of Nordheim equation, initially bounded and supercritical, becomes unbounded in finite time $T_{max}$ and develops a condensate in finite time $T_0 \geq T_{max}$.

An interesting fact that is worth noticing is that the quadratic terms in (1.1), [cf. (1.6)] that are in principle lower order terms, play a crucial role in the onset of blow-up. The reason is that they produce a transfer of mass from energies of order one to small energies.

We now sketch the main idea in the proof of the blow up result of this paper. The key ingredient is the blow-up condition for mild solutions in [3]. There are two main conditions needed to apply such a blow-up condition. First we need to have $f \geq \nu > 0$ in some average sense for small values of $\epsilon$. On the other hand, we need to have an amount of mass of order $\rho^{\theta_*}$, for some $\theta_* > 0$, in a interval $[0, \rho]$, with $\rho$ small. In this paper we prove that every bounded solution of the Nordheim equation satisfies these conditions for sufficiently long times. To this end we use mainly two arguments. We first prove that the quadratic terms of the Nordheim equation transport an amount of mass towards small values of the energy, and that this transport cannot be balanced by the corresponding loss terms. As a consequence we obtain an amount of mass of order $\nu R^2$ for some $\nu > 0$ in any interval $[0, R]$ for sufficiently long times. The second argument that we use is the existence of an increasing entropy for the Nordheim equation. The corresponding formula for the dissipation of the entropy can be used to prove that, at least along some sequences of time, the distribution $f$ approaches one stationary state of the Nordheim equation. The total energy and number of particles of the admissible stationary states obtained corresponds to the supercritical regime of the Bose–Einstein condensation. This implies that there exists a positive amount of mass in a small interval $[0, \rho]$ with $\rho > 0$ small for times sufficiently long. The condition in [3] then implies blow-up in finite time for the solutions of the Nordheim equation.

Similar arguments are applied to the weak solutions of (1.7), (1.8) in order to prove condensation in finite time.

We also remark that the blow-up and the condensation conditions are local. Therefore, it is not difficult to obtain initial data $f_0(x)$ yielding blow-up or condensation in finite time for subcritical initial data.

The plan of this paper is the following. In Sect. 2 we recall the concept of solution which we will use, as well as the Local Well-Posedness Theorem proved in [3]. Section 3 states the main results proved in this paper. Section 4 summarizes some results proved in [3] which will be used in the proof of the main result of this paper. Section 5 contains one of the key ingredients of this paper, namely, a lower estimate for the amount of mass contained in regions $\epsilon \in [0, R]$ with $R$ small. This estimate is due to the effect of the quadratic Boltzmann terms in (1.7). Section 6 contains a rigorous proof of the entropy dissipation formula for the solutions considered in this paper. Section 7 contains a technical Lemma that estimates the maximum amount of particles contained in regions $\epsilon \geq R$, with $R$ small, in terms of the total energy of the solution. Section 8 proves that for the so-called supercritical data, the distribution of particles $g(t, \epsilon)$ contains a positive amount of mass in the region where $\epsilon$ is small, at least for some subsequences of time. Section 9 contains the proof of the main blow up theorem of this paper. In Sect. 10 we prove the formation in finite time of a Dirac mass at the origin for weak solutions whose mass and energy are supercritical. Section 11 explains how to apply the result in [3] in order to obtain finite time blow-up and condensation for the solutions of (1.10) for some subcritical distributions of particles.
2. Well-Posedness Results: Weak and Mild Solutions

In order to formulate the main results of this paper we make need to recall some previous results about Eqs. (1.7), (1.8).

We first recall a well-posedness result obtained in [3]. To this end we make precise the concept of mild solution of (1.7), (1.8) that we will use.

2.1. Definition of mild solutions. Given \( \gamma \in \mathbb{R} \) we will denote as \( L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma) \) the space of functions such that:

\[
\| f \|_{L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma)} = \sup_{\epsilon \geq 0} \{(1 + \epsilon)\gamma f (\epsilon)\} < \infty.
\]

Notice that \( L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma) \) is a Banach space with the norm \( \| \cdot \|_{L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma)} \). Given \( T_2 > T_1 > 0 \), we define \( L^\infty _{loc} ([T_1, T_2]; L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma)) \) as the set of functions satisfying:

\[
\sup_{t \in K} \| f (t, \cdot) \|_{L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma)} < \infty
\]

for any compact \( K \subset [T_1, T_2] \). Notice that these spaces are not Banach spaces. We also define the space \( L^\infty ([T_1, T_2]; L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma)) \) which is the Banach space of functions such that:

\[
\| f \|_{L^\infty ([T_1, T_2]; L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma))} = \sup_{t \in [T_1, T_2]} \| f (t, \cdot) \|_{L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma)} < \infty.
\]

**Definition 2.1.** Suppose that \( \gamma > 3 \), \( T_2 > T_1 > 0 \). We will say that a function

\[
f \in L^\infty _{loc} ([T_1, T_2]; L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma))
\]

is a mild solution of (1.7), (1.8) if it satisfies:

\[
f (t, \epsilon_1) = f_0 (\epsilon_1) \Psi (t, \epsilon_1) + \frac{8\pi^2}{\sqrt{2}} \int_0^t \Psi (t, \epsilon_1) \int_0^\infty \int_0^\infty f_3 f_4 (1 + f_1 + f_2) W d\epsilon_3 d\epsilon_4 ds
\]

a.e. \( t \in [T_1, T_2] \), where:

\[
a (t, \epsilon_1) = \frac{8\pi^2}{\sqrt{2}} \int_0^\infty \int_0^\infty f_2 (1 + f_3 + f_4) W d\epsilon_3 d\epsilon_4, \quad \Psi (t, \epsilon_1)
\]

\[
= \exp \left( - \int_0^t a (s, \epsilon_1) ds \right). \tag{2.1}
\]

**Remark 2.2.** Since \( \gamma > 3 \) there exists a constant \( C > 0 \) such that, for any \( t \in [T_1, T_2] \):

\[
\int_0^\infty \int_0^\infty f_3 f_4 (1 + f_1 + f_2) W d\epsilon_3 d\epsilon_4 \leq C \| f \|_{L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma)} \left( 1 + \| f \|_{L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma)} \right)
\]

The term \( a (t, \epsilon_1) \) is bounded by \( C \left( 1 + \| f \|_{L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma)} \right) \int_0^\infty \int_0^\infty f_2 W d\epsilon_3 d\epsilon_4 \). By the definition of \( W \), and using \( \epsilon_2 \) as one of the integration variables, we estimate \( \int_0^\infty \int_0^\infty f_2 W d\epsilon_3 d\epsilon_4 \) as \( \int_0^\infty f_2 \left( \sqrt{\epsilon_2} + \sqrt{\epsilon_1} \right) W d\epsilon_2 \leq C \| f \|_{L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma)} \). Therefore, all the terms in (2.1) are well defined for \( T_1 \leq t < T_2 \) if \( f \in L^\infty _{loc} ([T_1, T_2]; L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma)) \).
2.2. Local well posedness of mild solutions. The following well-posedness result has been proved in [3].

**Theorem 2.3.** Suppose that $f_0 \in L^\infty \left( \mathbb{R}^+; (1 + \epsilon)^\gamma \right)$ with $\gamma > 3$. There exists $T > 0$ depending only on $\| f_0 (\cdot) \|_{L^\infty \left( \mathbb{R}^+; (1 + \epsilon)^\gamma \right)}$ and a unique mild solution of (1.7), (1.8) in the sense of Definition 2.1, $f \in L^\infty_{loc} \left( [0, T); L^\infty \left( \mathbb{R}^+; (1 + \epsilon)^\gamma \right) \right)$.

The obtained solution $f$ satisfies:

$$4\pi \frac{\sqrt{2}}{\sqrt{\epsilon}} \int_0^\infty f_0 (\epsilon) \epsilon^w d\epsilon = 4\pi \frac{\sqrt{2}}{\sqrt{\epsilon}} \int_0^\infty f (t, \epsilon) \epsilon^w d\epsilon, \ t \in (0, T), \ w \in \left\{ 1, \frac{3}{2} \right\}.$$  \hspace{1cm} (2.2)

The function $f$ is in the space $W^{1, \infty} \left( (0, T); L^\infty \left( \mathbb{R}^+ \right) \right)$ and it satisfies (1.7) a.e. $\epsilon \in \mathbb{R}^+$ for any $t \in (0, T_{\text{max}})$, with initial datum $f (\cdot, t) = f_0 (\cdot)$. Moreover, $f$ can be extended as a mild solution of (1.7), (1.8) to a maximal time interval $(0, T_{\text{max}})$ with $0 < T_{\text{max}} < \infty$. If $T_{\text{max}} < \infty$ we have:

$$\lim_{t \to T_{\text{max}}} \sup \| f (t, \cdot) \|_{L^\infty (\mathbb{R}^+)} = \infty$$ \hspace{1cm} (2.3)

2.3. Weak solutions. The Bose–Einstein condensation phenomena, at the level of the kinetic equation (1.7), (1.8), is related in the physical literature with the onset of a macroscopic fraction of particles at the energy level $\epsilon = 0$. In order to take that phenomena into account it is necessary to consider some notion of weak solutions for Eqs. (1.7), (1.8).

The theory of weak solutions of (1.7), (1.8) has been developed by Lu in [9–11]. It allows one to deal with measure-valued solutions and suits very well to the purpose of considering the finite time formation of Dirac mass in the solutions of (1.7), (1.8).

Since we are interested in the condensation phenomena, it is convenient to use the equation for the mass density $g$, instead of (1.7), (1.8) for $f$. Suppose that $g (t, \epsilon) = 4\pi \sqrt{2\epsilon} f (t, \epsilon)$ (cf. (4.7)). Then, formally (1.7), (1.8) becomes:

$$\partial_t g_1 = 32\pi^3 \int_0^\infty \int_0^\infty q \left( \frac{g}{4\pi \sqrt{2\epsilon}} \right) \Phi d\epsilon_3 d\epsilon_4$$ \hspace{1cm} (2.4)

$$\Phi = \min \left\{ \sqrt{\epsilon_1}, \sqrt{\epsilon_2}, \sqrt{\epsilon_3}, \sqrt{\epsilon_4} \right\}, \ \epsilon_2 = \epsilon_3 + \epsilon_4 - \epsilon_1$$ \hspace{1cm} (2.5)

We will denote as $\mathcal{M}_+ \left( \mathbb{R}^+; 1 + \epsilon \right)$ the set of Radon measures $g$ in $\mathbb{R}^+$ satisfying:

$$\int (1 + \epsilon) g (\epsilon) d\epsilon < \infty$$

We will use the notation $g (\epsilon)$ in spite of the fact that $g$ is a measure.

It is natural to say that, for some $T > 0$, a weak solution $g$ of (2.4), (2.5) develops a condensate in finite time $T$, if the following property holds:

$$\sup_{0 < t \leq T} \int_0^T g (t, \epsilon) d\epsilon > 0.$$ \hspace{1cm} (2.6)
Definition 2.4. We will say that \( g \in C \left( [0, T); M_+ \left( \mathbb{R}^+; (1 + \epsilon) \right) \right) \) is a weak solution of (2.4), (2.5) in \((0, T)\), with initial datum \( g_0 \in M_+ \left( \mathbb{R}^+; 1 + \epsilon \right)\), if, for any \( \varphi \in C^2_0 \left( [0, T), [0, \infty) \right)\), the following identity holds:

\[
- \int_{\mathbb{R}^+} g_0 (\epsilon) \varphi (0, \epsilon) \, d\epsilon = \int_0^T \int_{\mathbb{R}^+} g \partial_t \varphi \, d\epsilon dt + \frac{1}{2} \pi \int_0^T \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \frac{g_1 g_2 g_3 \Phi}{\sqrt{\epsilon_1 \epsilon_2 \epsilon_3}} Q \varphi \, d\epsilon_1 d\epsilon_2 d\epsilon_3 dt \]

where \( \Phi \) is as in (2.5) and:

\[
Q \varphi = \varphi (\epsilon_3) + \varphi (\epsilon_2 - \epsilon_3) - 2 \varphi (\epsilon_1) \quad (2.8)
\]

Definition 2.5. We say that \( f \) is a weak solution of (1.7), (1.8) in \((0, T)\) with initial datum \( f_0 \), if \( g_0 = 4 \pi \sqrt{2 \epsilon} f_0 (\epsilon) \in M_+ \left( \mathbb{R}^+; 1 + \epsilon \right)\), and \( g = 4 \pi \sqrt{2 \epsilon} f (t, \epsilon) \in C \left( [0, T); M_+ \left( \mathbb{R}^+; (1 + \epsilon) \right) \right) \) is a weak solution of (2.4), (2.5) on \((0, T)\), with initial datum \( g_0 \) in the sense of Definition 2.4.

The following result has been proved in [3] (Lemma 3.13).

Lemma 2.6. Suppose that \( \gamma > 3 \) and \( f \in L^\infty \left( [0, T); L^\infty \left( \mathbb{R}^+; (1 + \epsilon)^\gamma \right) \right) \) is a mild solution of (1.7), (1.8) in the sense of Definition 2.1. Then, \( f \) is also a weak solution of (1.7), (1.8) on \((0, T)\) in the sense of definition 2.5.

It has been proved by Lu in Theorem 2 of [9] that for all \( g_0 \in M_+ \left( \mathbb{R}^+; 1 + \epsilon \right)\), there exists a global weak solution of (2.4), (2.5) in the sense of the Definition 2.4. This solution satisfies (2.7), (2.8) for all \( \varphi \in C^2_0 \left( [0, \infty) \right)\) and with \( T = \infty \). Moreover the two quantities \( \int_{[0, \infty)} g(t, \epsilon) \, d\epsilon \) and \( \int_{[0, \infty)} e g(t, \epsilon) \, d\epsilon \) are constant in time, for all \( t \geq 0 \).

3. Statements of the Main Results

3.1. Subcritical and supercritical data. Phase diagram in terms of the energy and the density of particles. For isotropic distributions the steady states \( F_{BE} \) in (1.9) have \( p_0 = 0 \) and reduce to:

\[
F_{BE} \left( p \right) = F_{BE} \left( p; \alpha, \beta, m_0 \right) = m_0 \delta \left( p \right) + \frac{1}{\exp \left( \beta \left( \frac{|p|^2}{2} + \alpha \right) \right) - 1} \quad (3.1)
\]

with \( m_0 \geq 0 \), \( \beta \in (0, \infty) \), \( 0 \leq \alpha < \infty \) and \( \alpha \cdot m_0 = 0 \) \quad (3.2)

It is customary in the physical literature to denote \( \alpha \) as \( -\beta \mu \), where \( \mu < 0 \) is a quantity with units of energy termed as chemical potential. We will use the notation (3.2) in order to use nonnegative quantities in the arguments. If \( \alpha = 0 \) and \( m_0 = 0 \) the resulting distributions are the Planck distributions.

The following result shows that at equilibrium there exists a one-to-one relation between the values of the particle density and the energy and the values of the chemical potential, temperature and density of particles in the condensate state.
**Proposition 3.1.** Given $M > 0$, $E > 0$ there exists a unique steady state $F_{BE}(p; \alpha, \beta, m_0)$ in the family (3.2) such that:

$$\int_{\mathbb{R}^3} F_{BE}(p; \alpha, \beta, m_0) \, d^3 p = M, \quad \int_{\mathbb{R}^3} F_{BE}(p; \alpha, \beta, m_0) \frac{|p|^2}{2} \, d^3 p = E$$

We have $m_0 = 0$ iff

$$M \leq \frac{\zeta \left( \frac{3}{2} \right)}{\left( \frac{4\pi}{3} \right)^{\frac{3}{2}}} E^{\frac{3}{2}}. \quad (3.3)$$

where $\zeta (\cdot)$ is the Riemann function.

**Proof.** This result is well known and it can be found in classical texts of Statistical Physics (cf. for instance [1,6]). We sketch here the main arguments. Suppose that $m_0 = 0$. Then, since $\alpha \geq 0$ we have (cf. (1.9)):

$$M \leq \int_{\mathbb{R}^3} \frac{d^3 p}{\exp \left( \frac{\beta |p|^2}{2} \right) - 1} = 2\pi \left( \frac{2}{\beta} \right)^{\frac{3}{2}} \int_0^\infty \frac{x^{\frac{1}{2}} \, dx}{e^x - 1}$$

$$= 2\pi \left( \frac{2}{\beta} \right)^{\frac{3}{2}} \sum_{n=0}^\infty \int_0^\infty x^{\frac{1}{2}} e^{-x} e^{-nx} \, dx = \left( \frac{2\pi}{\beta} \right)^{\frac{3}{2}} \zeta \left( \frac{3}{2} \right) \quad (3.4)$$

where we have used spherical coordinates, the change of variables $x = \frac{\beta r^2}{2}$ as well as Taylor’s series to expand $(1 - e^{-x})^{-1}$. A similar computation yields:

$$E = \frac{1}{2} \int_{\mathbb{R}^3} \frac{|p|^2 \, d^3 p}{\exp \left( \frac{\beta |p|^2}{2} \right) - 1} = \pi \left( \frac{2}{\beta} \right)^{\frac{5}{2}} \int_0^\infty \frac{x^{\frac{3}{2}} \, dx}{e^x - 1}$$

$$= \pi \left( \frac{2}{\beta} \right)^{\frac{5}{2}} \sum_{n=0}^\infty \int_0^\infty x^{\frac{3}{2}} e^{-x} e^{-nx} \, dx = \frac{3}{4\pi} \left( \frac{2\pi}{\beta} \right)^{\frac{5}{2}} \zeta \left( \frac{5}{2} \right) \quad (3.5)$$

Then, if $m_0 = 0$ we obtain $M \leq \frac{\zeta \left( \frac{3}{2} \right)}{\left( \frac{4\pi}{3} \right)^{\frac{3}{2}}} E^{\frac{3}{2}}$. On the other hand, if $m_0 > 0$, we can argue as in the derivation of (3.4) and using the fact that $\alpha = 0$ we obtain $M > \left( \frac{2\pi}{\beta} \right)^{\frac{3}{2}} \zeta \left( \frac{3}{2} \right)$. Combining this formula with (3.4) it then follows that $M > \frac{\zeta \left( \frac{3}{2} \right)}{\left( \frac{4\pi}{3} \right)^{\frac{3}{2}}} E^{\frac{3}{2}}$, whence the Proposition follows. □

**Definition 3.2.** We will say that a couple of values $(M, E)$, such that $M > 0$ and $E > 0$, is in the subcritical region if (3.3) holds. On the contrary, if $M > \frac{\zeta \left( \frac{3}{2} \right)}{\left( \frac{4\pi}{3} \right)^{\frac{3}{2}}} E^{\frac{3}{2}}$ we will say that $(M, E)$ is in the supercritical region.
3.2. Blow-up Theorem for supercritical data. The main result of this paper about the finite time blow up of solutions is the following.

**Theorem 3.3.** Suppose that \( f_0 \in L^\infty (\mathbb{R}^+; (1 + \epsilon)^\gamma) \) with \( \gamma > 3 \). Let us denote as \( M, E \) the numbers:

\[
M = \frac{4\pi}{\zeta \left( \frac{3}{2} \right)} \left( \frac{4\pi}{3} \right)^{\frac{3}{5}} E^{\frac{3}{5}},
\]

Let us denote as \( f \in L^\infty_{loc} ([0, T_{\text{max}}); L^\infty (\mathbb{R}^+; (1 + \epsilon)^\gamma)) \) the mild solution of (1.7), (1.8) in Theorem 2.3 where \( T_{\text{max}} \) is the maximal existence time. Suppose that:

\[
M > \zeta \left( \frac{3}{2} \right) \left( \frac{4\pi}{3} \right)^{\frac{3}{5}} E^{\frac{3}{5}}.
\]

Then:

\[
T_{\text{max}} < \infty
\]  

**Remark 3.4.** Notice that \( M, E \) are the particle density and energy density associated to the distribution \( f_0 \). The numerical factors are due to the change of variables to spherical coordinates and to the fact that we use \( \epsilon \) instead of \( p \) as an integration variable.

Notice that Theorems 2.3 and Theorem 3.3 imply that for supercritical values of \((M, E)\), \( f \) blows-up in finite time:

**Corollary 3.5.** Suppose that the conditions of Theorem 3.3 hold. Then:

\[
\lim_{t \to T_{\text{max}}} \sup_{t \to T_{\text{max}}} \| f(t, \cdot) \|_{L^\infty(\mathbb{R}^+)} = \infty, \quad T_{\text{max}} < \infty
\]

3.3. Condensation Theorem for supercritical data. The main result of this paper about the condensation of solutions in finite time is the following.

**Theorem 3.6.** Let \( g_0 \in M_+ (\mathbb{R}^+; (1 + \epsilon)) \) satisfying

\[
4\pi \sqrt{2} \int_{\mathbb{R}^+} g_0 (\epsilon) d\epsilon = M, \quad 4\pi \sqrt{2} \int_{\mathbb{R}^+} g_0 (\epsilon) \epsilon d\epsilon = E.
\]

Suppose that \( M \) and \( E \) satisfy condition (3.7). Then, there exists \( T_0 = T_0(M, E) > 0 \) such that every weak solution \( g \) of (2.4), (2.5) in \((0, \infty)\) with initial data \( g_0 \) satisfies (2.6) for any \( T \geq T_0 \).

4. Summary of Some Results in [3]

We now recall some results which has been obtained in [3] which will be used in the Proof of the results of this paper.
4.1. Blow-up condition. One of the main ingredients in the Proof of Theorem 3.3 is the following condition for blow-up of mild solutions which has been proved in [3].

**Theorem 4.1.** There exist \( \theta_* > 0 \) such that, for all \( M > 0 \), \( E > 0 \), \( \nu > 0 \), \( \gamma > 3 \), there exists \( \rho_0 = \rho_0 (M, E, \nu) > 0 \), \( K^* = K^* (M, E, \nu) > 0 \), \( T_0 = T_0 (M, E) \) satisfying the following property. For any \( f_0 \in L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma) \) such that

\[
4\pi \sqrt{2} \int_{\mathbb{R}^+} f_0 (\epsilon) \sqrt{\epsilon} d\epsilon = M, \quad 4\pi \sqrt{2} \int_{\mathbb{R}^+} f_0 (\epsilon) \sqrt{\epsilon^2} d\epsilon = E,
\]

(4.1)

and

\[
\sup_{0 \leq \rho \leq \rho_0} \left[ \min \left\{ \inf_{0 \leq R \leq \rho} \frac{1}{\nu R^{3/2}} \int_0^R f_0(\epsilon) \sqrt{\epsilon} d\epsilon, \frac{1}{K^* \rho^{\theta_*}} \int_0^\rho f_0(\epsilon) \sqrt{\epsilon} d\epsilon \right\} \right] \geq 1,
\]

(4.2)

there exists a unique \( f \in L^\infty_{\text{loc}} ([0, T_{\text{max}}]; L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma)) \) mild solution of (1.7), (1.8) in the sense of Definition 2.1, with initial data \( f_0 \), defined for a maximal existence time \( T_{\text{max}} < T_0 \) and that satisfies:

\[
\limsup_{t \to T_{\text{max}}} \| f(\cdot, t) \|_{L^\infty (\mathbb{R}^+)} = \infty.
\]

The above Theorem means that initial data \( f_0 \in L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma) \), with a sufficiently large density around \( \epsilon = 0 \), blows up in finite time. More precisely, the condition (4.2) means that there exists \( \rho \in (0, \rho_0) \) satisfying:

\[
\int_0^R f_0(\epsilon) \sqrt{\epsilon} d\epsilon \geq \nu R^{3/2} \quad \text{for} \quad 0 < R \leq \rho, \quad \int_0^\rho f_0(\epsilon) \sqrt{\epsilon} d\epsilon \geq K^*(\rho)^{\theta_*},
\]

(4.3)

The second condition in (4.3) holds if the distribution \( f_0 \) has a mass sufficiently large in a ball with radius \( \rho \) for some \( \rho \) sufficiently small. The first condition is satisfied if \( f_0(\epsilon) \geq 3\nu/2 \) for all \( \epsilon \) sufficiently small. Since \( \theta_* \) might be small, the first condition in (4.3) does not imply the second.

Our results do not provide an explicit functional relation for the functions \( \rho_0 (M, E, \nu) \), \( K^* (M, E, \nu) \) and \( T_0 (M, E) \) in terms of their arguments. Therefore, for a given initial data \( f_0 \in L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma) \) it is not easy to check if condition (4.3) is satisfied. However, it has been verified in [3] that the class of functions \( f_0 \in L^\infty (\mathbb{R}^+; (1 + \epsilon)\gamma) \) satisfying such condition is not empty.

4.2. Condensation condition. The following result about finite time condensation for weak solutions of (1.7), (1.8) has been proved in [3].

**Theorem 4.2.** There exist \( \theta_* > 0 \) with the following property. For all \( M > 0 \), \( E > 0 \), \( \nu > 0 \), there exists \( \rho_0 = \rho_0 (M, E, \nu) > 0 \), \( K^* = K^* (M, E, \nu) > 0 \), \( T_0 = T_0 (M, E) \) such that for any weak solution of (2.4), (2.5) on \( (0, T_0) \) in the sense of Definition 2.4 with \( g_0 \in \mathcal{M}_+ (\mathbb{R}^+; (1 + \epsilon)) \) satisfying

\[
4\pi \sqrt{2} \int_{\mathbb{R}^+} g_0(\epsilon) d\epsilon = M, \quad 4\pi \sqrt{2} \int_{\mathbb{R}^+} \epsilon g_0(\epsilon) d\epsilon = E
\]

(4.4)

\[
\sup_{0 \leq \rho \leq \rho_0} \left[ \min \left\{ \inf_{0 \leq R \leq \rho} \frac{1}{\nu R^{3/2}} \int_0^R g_0(\epsilon) d\epsilon, \frac{1}{K^* \rho^{\theta_*}} \int_0^\rho g_0(\epsilon) d\epsilon \right\} \right] \geq 1,
\]

(4.5)

...
we have:

\[
\sup_{0 < t \leq T_0} \int_{[0]} g(t, \epsilon) d\epsilon > 0. \tag{4.6}
\]

4.3. Transfer of mass formula. We will use the following result, proved in [3] (Proposition 4.1), to estimate the rate of transfer of particles between different regions.

We recall that the density of particles for unit of energy is given by (cf. [3]):

\[
g(t, \epsilon) = 4\pi \sqrt{2\epsilon} f(t, \epsilon) \tag{4.7}
\]

**Proposition 4.3.** Suppose that \( g \) is a weak solution of (2.4), (2.5) in \((0, T)\), with initial datum \( g_0 \in \mathcal{M}_+([0, 1 + \epsilon]) \) in the sense of Definition 2.4. Suppose that \( \varphi \in C^1_0([0, T) \times [0, \infty)) \). Then, the function \( \psi_\varphi(t) = \int_{[0]} g(t, \epsilon) \varphi(t, \epsilon) d\epsilon \) is Lipschitz continuous in \( t \in [0, T] \) and the following identity holds:

\[
\partial_t \left( \int_{\mathbb{R}^+} g \varphi d\epsilon \right) = \int_{\mathbb{R}^+} g \partial_t \varphi d\epsilon + \frac{1}{2} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \frac{g_1 g_2 g_3 \Phi}{\sqrt{\epsilon_1 \epsilon_2 \epsilon_3}} G_{\varphi}(\epsilon_1, \epsilon_2, \epsilon_3) d\epsilon_1 d\epsilon_2 d\epsilon_3
\]

\[
+ \frac{\pi}{2} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \frac{g_1 g_2 \Phi}{\sqrt{\epsilon_1 \epsilon_2}} \mathcal{H}_{\varphi} d\epsilon_1 d\epsilon_2 d\epsilon_3, \quad \text{a.e. } t \in [0, T] \tag{4.8}
\]

with:

\[
\Phi = \min \left\{ \sqrt{\epsilon_1}, \sqrt{\epsilon_2}, \sqrt{\epsilon_3}, \sqrt{(\epsilon_1 + \epsilon_2 - \epsilon_3)} \right\} \tag{4.9}
\]

\[
\mathcal{H}_{\varphi} = \varphi(\epsilon_3) + \varphi(\epsilon_1 + \epsilon_2 - \epsilon_3) - \varphi(\epsilon_1) - \varphi(\epsilon_2) \tag{4.10}
\]

\[
G_{\varphi}(\epsilon_1, \epsilon_2, \epsilon_3) = \frac{1}{6} \sum_{\sigma \in S^3} H_{\varphi}(\epsilon_{\sigma(1)}, \epsilon_{\sigma(2)}, \epsilon_{\sigma(3)}) \Phi(\epsilon_{\sigma(1)}, \epsilon_{\sigma(2)}, \epsilon_{\sigma(3)})
\]

where \( S^3 \) is the group of permutations of \( \{1, 2, 3\} \). Moreover, for any convex function \( \varphi \) we have:

\[
G_{\varphi}(\epsilon_1, \epsilon_2, \epsilon_3) \geq 0, \quad (\epsilon_1, \epsilon_2, \epsilon_3) \in \mathbb{R}^3_+
\]

\[
G_{\varphi}(\epsilon_1, \epsilon_2, \epsilon_3) = G_{\varphi}(\epsilon_{\sigma(1)}, \epsilon_{\sigma(2)}, \epsilon_{\sigma(3)}) \quad \text{for any } \sigma \in S^3 \tag{4.11}
\]

**Proof.** It is just a consequence of Lemma 3.13 and Theorem 4.2 in [3]. \( \square \)

5. A Lower Estimate for the Mass in \([0, R]\) with \( R \) Small

**Proposition 5.1.** Suppose that \( g \) is a weak solution of (2.4), (2.5) in \((0, T)\), with initial datum \( g_0 \in \mathcal{M}_+([\mathbb{R}^+; 1 + \epsilon]) \) in the sense of Definition 2.4. Then, there exist \( T_1 = T_1(E, M) \), \( \rho_1 = \rho_1(E, M) \) and \( K = K(E, M) \) such that if \( T_{\max} \geq T_1(E, M) \), we have:

\[
\int_0^R g(\epsilon, t) d\epsilon \geq KR^3 \quad \text{for any } 0 < R \leq \rho_1(E, M) \tag{5.1}
\]

for any \( t \geq T_1(E, M) \).
Proof. We will assume that \( \rho_1 \leq 1 \). Given \( 0 < R \leq 1 \), we define the following family of test functions:
\[
\varphi_R (\epsilon) = \left( 1 - \frac{\epsilon}{R} \right)_+
\]
where \((s)_+ = \max\{s, 0\}\). Using Proposition 4.3 we obtain:
\[
\partial_t \left( \int g \varphi_R d\epsilon \right) \geq \frac{\pi}{2} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \frac{g_1 g_2 \Phi}{\sqrt{\epsilon_1 \epsilon_2}} H_{\varphi_R} d\epsilon_1 d\epsilon_2 d\epsilon_3, \quad a.e. \ t \in [0, T]
\]
where we use the fact that \( \varphi_R \) is convex, and then (4.11) holds. Using (4.10) as well as the fact that \( \varphi (\epsilon_1 + \epsilon_2 - \epsilon_3) \geq 0 \) we obtain for \( a.e. \ t \in [0, T] \):
\[
\partial_t \left( \int g \varphi_R d\epsilon \right) \geq I_1 - I_2 \tag{5.2}
\]
where
\[
I_1 = \frac{\pi}{2} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \frac{g_1 g_2 \Phi}{\sqrt{\epsilon_1 \epsilon_2}} \varphi_R (\epsilon_3) d\epsilon_1 d\epsilon_2 d\epsilon_3 \tag{5.3}
\]
\[
I_2 = \frac{\pi}{2} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \frac{g_1 g_2 \Phi}{\sqrt{\epsilon_1 \epsilon_2}} \left[ \varphi_R (\epsilon_1) + \varphi_R (\epsilon_2) \right] d\epsilon_1 d\epsilon_2 d\epsilon_3 \tag{5.4}
\]
We estimate \( I_2 \), using the definition of \( \Phi \), as well as the symmetry with respect to the permutations of \( \epsilon_1, \epsilon_2 \), as follows:
\[
I_2 = \pi \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \frac{g_1 g_2 \Phi}{\sqrt{\epsilon_1 \epsilon_2}} \varphi_R (\epsilon_1) d\epsilon_1 d\epsilon_2 d\epsilon_3 \\
\leq \pi \int_{0}^{R} g_1 \varphi_R (\epsilon_1) d\epsilon_1 \int_{\mathbb{R}^+} g_2 d\epsilon_2 \left[ \min \left\{ \sqrt{\epsilon_1}, \sqrt{\epsilon_2} \right\} \left( \epsilon_1 + \epsilon_2 \right) \right] \\
\leq 2 \int_{\mathbb{R}^+} g_2 \max \left\{ 1, \sqrt{\epsilon_2} \right\} d\epsilon_2 \leq 2 (M + E)
\]
where we use that \( \Phi \leq \min \left\{ \sqrt{\epsilon_1}, \sqrt{\epsilon_2} \right\} \) and we compute the integral in \( \epsilon_3 \). Notice that
\[
\min \left\{ \sqrt{\epsilon_1}, \sqrt{\epsilon_2} \right\} \leq 2 \max \left\{ 1, \sqrt{\epsilon_1}, \sqrt{\epsilon_2} \right\}.
\]
Then, since \( \epsilon_1 \leq R \leq 1 \):
\[
\int_{\mathbb{R}^+} g_2 \left[ \min \left\{ \sqrt{\epsilon_1}, \sqrt{\epsilon_2} \right\} \left( \epsilon_1 + \epsilon_2 \right) \right] d\epsilon_2 \leq 2 \int_{\mathbb{R}^+} g_2 \max \left\{ 1, \sqrt{\epsilon_2} \right\} d\epsilon_2 \\
\leq 2 \int_{\mathbb{R}^+} g_2 \left( 1 + \epsilon_2 \right) d\epsilon_2 \leq 2 (M + E)
\]
\[
I_2 \leq 2 \pi (M + E) \int_{0}^{R} g \varphi_R d\epsilon \tag{5.5}
\]
We now estimate \( I_1 \) assuming that \( \int_{0}^{R} g \varphi_R d\epsilon \leq \frac{M}{4} \). Using the fact that \( \int g d\epsilon = M \) we have:
\[
\int_{\frac{R}{2}}^{\infty} g d\epsilon \geq \frac{M}{8} \tag{5.6}
\]
Indeed, suppose that \( \int_{\mathbb{R}^2} g \, d\epsilon < \frac{M}{8} \), then \( \int_{\mathbb{R}^2} g \, d\epsilon \geq \frac{7M}{8} \), whence, since \( \varphi_R \geq \frac{1}{2} \) for \( 0 \leq \epsilon \leq \frac{R}{2} \), we have \( \int_{\mathbb{R}^2} g \varphi_R d\epsilon \geq \frac{7M}{16} > \frac{M}{4} \) against the assumption, whence (5.6) follows.

Using the definition of \( \Phi \) (cf. (4.9)) we obtain:

\[
I_1 = \frac{\pi R^3}{2} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} J\left(\frac{\epsilon_1}{R}, \frac{\epsilon_2}{R}\right) g_1 g_2 \, d\epsilon_1 d\epsilon_2
\]

(5.7)

where:

\[
J(\eta_1, \eta_2) = \int_0^{\eta_1+\eta_2} \min\{\sqrt{\eta_1}, \sqrt{\eta_2}, \sqrt{\eta_3}, \sqrt{(\eta_1 + \eta_2 - \eta_3)}\} (1 - \eta_3) \, d\eta_3
\]

(5.8)

Notice that, if \( \eta_1 \geq \frac{1}{2}, \eta_2 \geq \frac{1}{2} \) we have \( J(\eta_1, \eta_2) \geq c_0 > 0 \) where \( c_0 \) is a number independent on \( R \). Then:

\[
I_1 \geq \frac{\pi c_0 R^3}{2} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \frac{g_1 g_2}{\sqrt{\epsilon_1 \epsilon_2}} \, d\epsilon_1 d\epsilon_2 = \frac{\pi c_0 R^3}{2} \left( \int_{\mathbb{R}^+} \frac{g}{\sqrt{\epsilon}} \, d\epsilon \right)^2
\]

(5.9)

Due to the boundedness of the energy we have:

\[
\int_{L}^{\infty} g \, d\epsilon \leq \frac{1}{L} \int_{L}^{\infty} g \, d\epsilon \leq \frac{E}{L}
\]

Then, if \( L \geq \frac{16E}{M} \), \( \int_{L}^{\infty} g \, d\epsilon \leq \frac{M}{16} \), whence, using (5.6):

\[
\int_{\mathbb{R}^2} g \, d\epsilon \geq \frac{M}{16}
\]

Therefore (5.9) yields:

\[
I_1 \geq \frac{\pi c_0 R^3}{2} \left( \int_{\mathbb{R}^+} \frac{g}{\sqrt{\epsilon}} \, d\epsilon \right)^2 \geq \frac{\pi c_0 R^3}{2} \left( \int_{\mathbb{R}^+} g \, d\epsilon \right)^2 \geq \frac{\pi c_0 M^2 R^3}{512L}
\]

We have then obtained that there exists \( \alpha = \alpha(E, M) \) such that, if \( \int_{\mathbb{R}^2} g \varphi_R d\epsilon \leq \frac{M}{4} \):

\[
I_1 \geq \alpha R^3.
\]

(5.10)

Combining (5.2), (5.5) and (5.10) we obtain:

\[
\partial_t \left( \int g \varphi_R d\epsilon \right) \geq \alpha R^3 - 2\pi (M + E) \int_0^R g \varphi_R d\epsilon \quad \text{if} \quad \int_0^R g \varphi_R d\epsilon \leq \frac{M}{4}
\]

(5.11)

Choosing \( R \leq \rho_1 < \left( \frac{(\pi(M+E)M)}{\alpha} \right)^{\frac{3}{2}} \) it follows that, for \( \int_0^R g \varphi_R d\epsilon \leq \frac{\alpha R^3}{4\pi(M+E)} \), we would have also \( \int_0^R g \varphi_R d\epsilon < \frac{M}{4} \) and the inequality (5.11) holds. This implies that
\[ \int g \varphi_R d\epsilon \text{ increases exponentially until reaching the value } \frac{\alpha R^2}{4\pi (M+E)} \text{ or larger in a time which depends only on } M \text{ and } E. \text{ If } \int_0^R g \varphi_R d\epsilon > \frac{M}{4} \text{ the inequality } \int g \varphi_R d\epsilon \geq \frac{\alpha R^2}{4\pi (M+E)} \text{ is automatically satisfied, due to our choice of } \rho. \text{ On the other hand, if } \frac{\alpha R^2}{4\pi (M+E)} \leq \int_0^R g \varphi_R d\epsilon \leq \frac{M}{4} \text{ the value of } \int_0^R g \varphi_R d\epsilon \text{ remains in that region due to (5.11). Therefore, there exists } T_1 = T_1 (M, E) \text{ such that if } T_1 (M, E) \leq T_{\text{max}}:\]

\[ \frac{\alpha R^2}{4\pi (M+E)} \leq \int g \varphi_R d\epsilon \leq \int_0^R g d\epsilon, \text{ for } t \geq T_1 (M, E) \]

whence the result follows. \(\Box\)

6. Dissipation of Entropy Formula

We now formulate the formula for the dissipation of the entropy. The entropy associated to the bosonic, isotropic quantum Boltzmann equation (1.7), (1.8) is given by:

\[ S[f] = \int_{\mathbb{R}^+} \left[ (1 + f) \log (1 + f) - f \log (f) \right] \sqrt{\epsilon} d\epsilon \] (6.1)

We also define, for any given \( f \) the dissipation of entropy by means of:

\[ D[f] = \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \frac{f_j (1 + f_j)}{(1 + f_j)} \frac{f_k (1 + f_k)}{(1 + f_k)} \left[ Q_{1,2} - Q_{3,4} \right] \times \left[ \log (Q_{1,2}) - \log (Q_{3,4}) \right] \Phi d\epsilon_1 d\epsilon_2 d\epsilon_3 \] (6.2)

where:

\[ Q_{j,k} = \frac{f_j}{(1 + f_j)} \frac{f_k}{(1 + f_k)}, \quad j, k \in \{1, 2, 3, 4\} \]

\[ \epsilon_4 = \epsilon_1 + \epsilon_2 - \epsilon_3, \quad \Phi = \min \left\{ \sqrt{(\epsilon_1)_+}, \sqrt{(\epsilon_2)_+}, \sqrt{(\epsilon_3)_+}, \sqrt{(\epsilon_4)_+} \right\} \]

Formulas for the dissipation of the entropy for suitably truncated kernels \( W \) and solutions in \( L^1 \) have been proved in [10]). Since we are working here with mild solutions we have decided to write a new proof of the dissipation of energy formula.

**Proposition 6.1.** Suppose that \( f_0 \in L^\infty (\mathbb{R}^+; (1 + \epsilon)^\gamma) \) with \( \gamma > 3 \), and \( f_0 \neq 0 \). Suppose that \( f \in L^\infty_{\text{loc}} ([0, T_{\text{max}}]; L^\infty (\mathbb{R}^+; (1 + \epsilon)^\gamma)) \) is the mild solution of (1.7), (1.8) with initial datum \( f_0 \) as in Theorem 4.1. Then, there exists \( C = C(E, M) \) such that:

\[ |S[f(\cdot, t)]| \leq C(E, M), \quad 0 \leq t < T_{\text{max}} \] (6.3)

For any \( T_1 \) and \( T_2 \) such that \( 2T_0 < T_1 < T_2 \leq T_{\text{max}} \), where \( T_0 \) as in proposition (5.1), we have:

\[ 0 \leq D[f(\cdot, t)] \leq C(T_1, T_2) < \infty, \quad T_1 \leq t \leq T_2 \]

for some constant \( C(T_1, T_2) \). Moreover, the following identity holds:

\[ S[f](T_2) - S[f](T_1) = \int_{T_1}^{T_2} D[f(\cdot, t)] dt \] (6.4)
Proof. As a first step we prove (6.3). To this end we use the following inequalities:

\[
\begin{align*}
(1 + f) \log (1 + f) - f \log (f) & \leq Cf \quad \text{if } f \geq 1 \\
(1 + f) \log (1 + f) - f \log (f) & \leq Cf |\log (f)| \quad \text{if } 0 \leq f \leq 1
\end{align*}
\]

We then can estimate \( S[f] \) for any \( f \in L^\infty (\mathbb{R}^+ ; (1 + \epsilon)') \), \( \gamma > 3 \) as follows. We have the inequalities:

\[
S[f] = \int_{\{ f \geq 1 \}} \cdots \sqrt{\epsilon} d\epsilon + \int_{\{ f < 1, \ |\log (f)| < \sqrt{\epsilon} \}} \cdots \sqrt{\epsilon} d\epsilon + \int_{\{ f < 1, \ |\log (f)| \geq \sqrt{\epsilon} \}} \cdots \sqrt{\epsilon} d\epsilon
\]

\[
\leq C \int f \sqrt{\epsilon} d\epsilon + C \int f \epsilon^2 d\epsilon + C \int_{\{ f < \exp (-\epsilon) \}} \sqrt{f} \left( \sqrt{f} |\log (f)| \right) \sqrt{\epsilon} d\epsilon
\]

\[
\leq C (M + E) + C \int \exp \left( -\frac{\epsilon}{2} \right) d\epsilon = C (M, E)
\]

whence (6.3) follows.

We now need a lower estimate for \( f(\epsilon, t) \), \( t > 0 \) in order to ensure the convergence of the integrals in (6.2). To this end we use methods inspired in the ideas used by Carleman to prove the \( H \)–Theorem for the classical Boltzmann equation (cf. [2], Section 5). We claim that for any \( \omega > 0 \) and \( 0 < T_1 \leq T_2 \), there exists \( C_{T_1, T_2, \omega} \) such that:

\[
f(\epsilon, t) \geq C_{T_1, T_2, \omega} \exp \left( -\epsilon^{1+\omega} \right), \quad T_1 \leq t \leq T_2
\]

(6.5)

where the constant \( C_{T_1, T_2, \omega} \) depends also on \( f_0 \).

In order to obtain (6.5), we first remark that the mild solutions of (1.7), (1.8) satisfy (cf. [3], Lemma 3.7):

\[
\partial_t f_1 + \pi M \sqrt{\epsilon_1} f_1 \geq \frac{8\pi^2}{\sqrt{2}} \int_0^\infty \int_0^\infty f_3 f_4 (1 + f_1 + f_2) W d\epsilon_3 d\epsilon_4
\]

\[
\geq \frac{8\pi^2}{\sqrt{2}} \int_0^\infty \int_0^\infty f_3 f_4 W d\epsilon_3 d\epsilon_4
\]

(6.6)

for a.e. \( t \in [T_1, T_2] \) and where \( C_0 > 0 \).

Since \( f_0 \neq 0 \) there exists an interval with the form \( (R_1, \theta R_1) \) with \( R_1 > 0 \) and \( \theta > 1 \) perhaps close to one, such that \( \int_{R_1}^{\theta R_1} f_0 d\epsilon > 0 \). Moreover, due to the continuity of the mild solutions in time in the weak topology in space it follows that, assuming that \( \tilde{t} \) is small we have:

\[
\int_{R_1}^{\theta R_1} f(t, \epsilon) d\epsilon \geq m_1 > 0, \quad 0 \leq t \leq \tilde{t}
\]

(6.7)

Let us choose \( \eta > 0 \) satisfying \((2 - \eta) \theta < 2, \ (2 - \eta) > \theta > 1 \). We can then derive a lower estimate for \( W \) if \( \epsilon_1 \in ((2 - \eta) R_1, (2 - \eta) \theta R_1) \). Combining (6.6) and (6.7) we obtain the estimate:

\[
\partial_t f_1 + \pi M \sqrt{\epsilon_1} f_1 \geq K_{\eta, \theta} \left( \int_{R_1}^{\theta R_1} f d\epsilon \right)^2, \quad \epsilon_1 \in (\theta R_1, (2 - \eta) \theta R_1)
\]

(6.8)
Iterating this argument we obtain the chain of inequalities:

\[ \partial_t f_1 + \pi M \sqrt{\epsilon_1} f_1 \geq K_{\eta, \theta} \left( \int_{R_n}^{\theta R_n} f \, d\epsilon \right)^2, \quad \epsilon_1 \in (\theta R_n, \theta R_{n+1}) \quad (6.9) \]

with:

\[ R_{n+1} = (2 - \eta) R_n. \quad (6.10) \]

Let us consider the sequence of positive times: \( t_n = \bar{t} - \tau_n \) with \( \tau_n = \frac{b}{\sqrt{R_n}} \) with \( 0 < b < 1 \), independent of \( n \). Using the fact that \( f \geq 0 \) we obtain, using Duhamel’s formula:

\[
\begin{align*}
  f(t, \epsilon_1) &\geq K_{\eta, \theta} \int_{t_n}^{t} \exp \left( -\pi M \sqrt{\epsilon_1} (s - t_n) \right) \left( \int_{R_n}^{\theta R_n} f(s, \epsilon) \, d\epsilon \right)^2 \, ds \\
  &\text{for a.e.} \, \epsilon_1 \in (\theta R_n, \theta R_{n+1})
\end{align*}
\]

(6.11)

If we assume that \( b \) is small, depending only on \( \bar{t} \), we would obtain that \( t_n > 0 \), for all \( n \geq 1 \). Using (6.11) we then obtain:

\[
\begin{align*}
  f(t, \epsilon_1) &\geq K_{\eta, \theta} a \int_{t_n}^{t} \left( \int_{R_n}^{\theta R_n} f(s, \epsilon) \, d\epsilon \right)^2 \, ds, \quad \epsilon_1 \in (\theta R_n, \theta R_{n+1})
\end{align*}
\]

(6.12)

for some \( a > 0 \) independent on \( n \). Applying (6.7) and (6.12) with \( n = 1 \) in the interval \( (R_2, \theta R_2) \subset (\theta R_1, \theta R_2) \), we obtain:

\[
\begin{align*}
  f(t, \epsilon_1) &\geq K_{\eta, \theta} a (t - t_2) (m_1)^2, \quad \epsilon_1 \in (R_2, \theta R_2), \quad \text{a.e.} \, t \in [t_2, \bar{t}]
\end{align*}
\]

(6.13)

Integrating this inequality in \( (R_2, \theta R_2) \) we obtain:

\[
\int_{R_2}^{\theta R_2} f(t, \epsilon) \, d\epsilon \geq m_2 = K_{\eta, \theta} a (\theta - 1) R_1 (t - t_2) (m_1)^2, \quad \text{a.e.} \, t \in [t_2, \bar{t}]
\]

(6.14)

Due to the definition of the sequence \( \{t_n\} \) we have:

\[
(t_3 - t_2) = (\bar{t} - \tau_3 - t_2) = (\tau_2 - \tau_3) = \frac{b}{\sqrt{R_2}} \left( 1 - \frac{1}{\sqrt{2 - \eta}} \right) \geq \frac{b \sqrt{2 - \eta}}{\sqrt{R_3}} \left( 1 - \frac{1}{\sqrt{2}} \right)
\]

Using (6.14) with \( t = t_3 \) it then follows that:

\[
m_2 \geq K_{\eta, \theta, a, b} \frac{R_1}{\sqrt{R_2}} m_1^2 \geq C_{\eta, \theta, a, b, R_1} m_1^2
\]

Iterating the argument it then follows that:

\[
m_{n+1} \geq C_{\eta, \theta, a, b, R_1} (2 - \eta)^{n-1} m_n^2, \quad n = 1, 2, 3, ...
\]

Moreover, since the term \((2 - \eta)^2\) increases to infinity we have that, after a finite number of steps the factor in front of \( m_n^2 \) becomes larger than one. We obtain lower estimates for \( m_{n_0} \) in terms of the first term. Then:

\[
m_{n+1} \geq m_n^2, \quad n \geq n_0
\]
Iterating we then obtain:

$$m_n \geq \left( m_{n_0} \right)^{2^{n-n_0}}, \quad n \geq n_0$$

Since $m_{n_0}$ is a fixed number, in general smaller than one we obtain:

$$m_n \geq \exp \left( -\tilde{\beta}_1 2^{n-n_0} \right)$$

with $\tilde{\beta}_1 > 0$ independent on $n$. Since $R_n$ is of order $(2-\eta)^n$ this implies an estimate of the form:

$$m_n \geq C \exp \left( -\tilde{\beta} R_n^{1+\omega} \right), \quad n = 1, 2, 3, \ldots$$

for some $\tilde{\beta} > 0, C > 0, \omega > 0$ independent on $n$, where moreover $\omega$ is such that $1 + \omega > \frac{\log 2}{\log (2-\eta)}$. Notice that, since $\eta > 0$ may be taken as small as we wish by taking $\theta$ sufficiently close to 1, the value of $\omega$ may be as small as we need.

Using now (6.12) as well as the fact that the union of the intervals $(R_n, \theta R_n), \ n \geq 1$ cover the whole interval $(R_1, \infty)$ except a set of measure zero, we obtain:

$$f(t, \epsilon) \geq C_{T_1, T_2, \omega} \exp \left( -\epsilon^{1+\omega} \right), \quad \epsilon \geq R_1, \quad 0 < T_1 \leq t \leq T_2 \quad (6.15)$$

where the value of $\omega$ may have been changed from its previous value in order to eliminate the constant $\tilde{\beta}$ from the exponential, but still remaining as small as we need. The constant $C_{T_1, T_2, \omega}$ depends on $f_0$.

In order to obtain a lower bound for small values of $\epsilon \in (0, R_1)$ we use again (6.6). By (6.15), for any $\epsilon_1 > 0$ we have:

$$\partial_t f_1 + \pi M \sqrt{\epsilon_1} f_1 \geq \frac{8\pi^2}{\sqrt{2}} \int_0^\infty \int_0^\infty f_3 f_4 W d\epsilon_3 d\epsilon_4$$

$$\geq \frac{8\pi^2}{\sqrt{2}} \int_{2R_1}^\infty \int_0^\epsilon_1 f_3 f_4 W d\epsilon_3 d\epsilon_4$$

$$\geq \frac{C}{\sqrt{\epsilon_1}} \int_0^{\epsilon_1} \sqrt{\epsilon_3} f_3 d\epsilon_3. \quad (6.16)$$

Using now Proposition (5.1) we have, for all $\epsilon_1 \in (0, \rho(E, M))$:

$$\int_0^{\epsilon_1} \sqrt{\epsilon_3} f_3 d\epsilon_3 \geq K \epsilon_1^{3/2}, \quad \text{for } t \geq T_0. \quad (6.17)$$

>From (6.16) and (6.17) we deduce

$$\partial_t f_1 + \pi M \sqrt{\epsilon_1} f_1 \geq C \epsilon_1, \quad \text{for } t \geq T_0,$$

and therefore, after integration in time from $T_*$ to $t$ for any $T_* > T_0$:

$$f(t, \epsilon_1) \geq C \sqrt{\epsilon_1} \left( 1 - e^{-\pi M \sqrt{\epsilon_1} (t-T_*)} \right), \quad \text{for } t > T_*.$$

If moreover $(t - T_*) < 1$:

$$f(t, \epsilon_1) \geq C \epsilon_1 t \geq C(T_1, T_2) \epsilon_1.$$
This shows that for some positive constant $C_{T_1, T_2, \omega}$:

$$f(t, \varepsilon_1) \geq C_{T_1, T_2, \omega} \varepsilon_1, \quad \varepsilon_1 \in (0, \rho), \quad \frac{3T_0}{2} < T_1 \leq t < T_2.$$  

where $\rho$ is as in Proposition (5.1). Arguing as in the proof of formula (6.15) above, we deduce after a finite number of iterations that for some positive constant $C_{T_1, T_2, \omega}$:

$$f(t, \varepsilon_1) \geq C_{T_1, T_2, \omega} \varepsilon_1, \quad \varepsilon_1 \in (0, R_1), \quad 2T_0 < T_1 \leq t < T_2, \quad (6.18)$$

where the constant $C_{T_1, T_2, \omega}$ might change from line to line.

We deduce then from (6.15) and (6.18):

$$f(t, \varepsilon_1) \geq C_{T_1, T_2, \omega} \varepsilon_1 \exp \left(-\varepsilon^{1+\omega}\right), \quad \varepsilon_1 > 0, \quad T_0(E, M) < T_1 \leq t \leq T_2. \quad (6.19)$$

Using (6.19) we obtain:

$$|\log(f)| \leq C_{T_1, T_2, \omega} \left(1 + |\log \varepsilon| + \varepsilon^{1+\omega}\right), \quad \varepsilon \geq 0, \quad 0 < T_1 \leq t \leq T_2. \quad (6.20)$$

We now use (6.20) to show that the different integral terms appearing in the formula of the dissipation of the entropy (cf. (6.2)) are finite. Due to the boundedness of $f$ we just need to show that the following integrals are finite:

\[
\int \int \int f_1 f_2 \left(\log \left(\frac{f_1}{1 + f_1}\right) + \log \left(\frac{f_2}{1 + f_2}\right)\right) \Phi d\varepsilon_1 d\varepsilon_2 d\varepsilon_3 \\
\int \int \int f_1 f_2 \left(\log \left(\frac{f_3}{1 + f_3}\right) + \log \left(\frac{f_4}{1 + f_4}\right)\right) \Phi d\varepsilon_1 d\varepsilon_2 d\varepsilon_3 \\
\int \int \int f_3 f_4 \left(\log \left(\frac{f_1}{1 + f_1}\right) + \log \left(\frac{f_2}{1 + f_2}\right)\right) \Phi d\varepsilon_1 d\varepsilon_2 d\varepsilon_3 \\
\int \int \int f_3 f_4 \left(\log \left(\frac{f_3}{1 + f_3}\right) + \log \left(\frac{f_4}{1 + f_4}\right)\right) \Phi d\varepsilon_1 d\varepsilon_2 d\varepsilon_3
\]

where $\varepsilon_4 = \varepsilon_1 + \varepsilon_2 - \varepsilon_3$. Replacing the variable $\varepsilon_4$ by the variable $\varepsilon_1$ in the last two integrals, and relabelling the number of the resulting integration variables (namely $\varepsilon_2, \varepsilon_3, \varepsilon_4$ to $\varepsilon_1, \varepsilon_2, \varepsilon_3$) we reduce the estimate of the last two integrals to the first two ones. Using now the symmetry of the variables $\varepsilon_1, \varepsilon_2$ we are left only with the three different terms:

\[
I_1 = \int \int \int f_1 f_2 \left(\log \left(\frac{f_1}{1 + f_1}\right)\right) \Phi d\varepsilon_1 d\varepsilon_2 d\varepsilon_3 \\
I_2 = \int \int \int f_1 f_2 \left(\log \left(\frac{f_3}{1 + f_3}\right)\right) \Phi d\varepsilon_1 d\varepsilon_2 d\varepsilon_3, \\
I_3 = \int \int \int f_1 f_2 \left(\log \left(\frac{f_4}{1 + f_4}\right)\right) \Phi d\varepsilon_1 d\varepsilon_2 d\varepsilon_3
\]

Using (6.20) and the boundedness of $f$ we obtain:

\[
I_1 \leq C \int \int \int f_1 f_2 \left(1 + \varepsilon_1^{1+\omega}\right) \Phi d\varepsilon_1 d\varepsilon_2 d\varepsilon_3 \\
= C \int \int \int_{\varepsilon_1 \geq \varepsilon_2} \varepsilon \Phi d\varepsilon_1 d\varepsilon_2 d\varepsilon_3 + C \int \int \int_{\varepsilon_1 < \varepsilon_2} \varepsilon \Phi d\varepsilon_1 d\varepsilon_2 d\varepsilon_3
\]
We now use that $\Phi \leq \sqrt{\epsilon_2}$ in the first integral and $\Phi \leq \sqrt{\epsilon_1}$ in the second. Then, since $\epsilon_3 \leq \epsilon_1 + \epsilon_2$

$$I_1 \leq C \int \int_{\{\epsilon_1 \geq \epsilon_2\}} f_1 f_2 \left( 1 + \epsilon_1^{1+\omega} + \| \log \epsilon_1 \| \right) \epsilon_1 \sqrt{\epsilon_2} d\epsilon_1 d\epsilon_2$$

$$+ C \int \int \int_{\{\epsilon_1 < \epsilon_2\}} f_1 f_2 \left( 1 + \epsilon_1^{1+\omega} + \| \log \epsilon_1 \| \right) \epsilon_2 \sqrt{\epsilon_1} d\epsilon_1 d\epsilon_2$$

Since, as it has been indicated before, the value of $\omega$ in (6.20) may be chosen as small as we need, we will assume in the following that $\omega < (\gamma - 3)$. Then, using that $f \leq \frac{C}{(1+\epsilon)^\gamma}$:

$$I_1 \leq C \int \int_{\{\epsilon_1 \geq \epsilon_2\}} (1 + \epsilon_1)^{-\gamma} (1 + \epsilon_2)^{-\gamma} \left( 1 + \epsilon_1^{1+\omega} + \| \log \epsilon_1 \| \right) \epsilon_1 \sqrt{\epsilon_2} d\epsilon_1 d\epsilon_2$$

$$+ C \int \int \int_{\{\epsilon_1 < \epsilon_2\}} (1 + \epsilon_1)^{-\gamma} (1 + \epsilon_2)^{-\gamma} \left( 1 + \epsilon_1^{1+\omega} + \| \log \epsilon_1 \| \right) \epsilon_2 \sqrt{\epsilon_1} d\epsilon_1 d\epsilon_2$$

$$\leq C.$$

In order to estimate $I_2$ and $I_3$ we use a symmetrization argument that yields:

$$I_2 \leq C \int \int \int_{\{\epsilon_1 \geq \epsilon_2\}} (1 + \epsilon_1)^{-\gamma} (1 + \epsilon_2)^{-\gamma} \left( 1 + \epsilon_3^{1+\omega} + \| \log \epsilon_3 \| \right) \Phi d\epsilon_1 d\epsilon_2 d\epsilon_3$$

$$\leq C \int \int \int_{\{\epsilon_1 \geq \epsilon_2\}} (1 + \epsilon_1)^{-\gamma} (1 + \epsilon_2)^{-\gamma} \left( 1 + \epsilon_1^{1+\omega} + \| \log \epsilon_1 \| \right) \epsilon_1 \sqrt{\epsilon_2} d\epsilon_1 d\epsilon_2$$

$$\leq C$$

$$I_3 \leq C \int \int \int_{\{\epsilon_1 \geq \epsilon_2\}} (1 + \epsilon_1)^{-\gamma} (1 + \epsilon_2)^{-\gamma} \left( 1 + \epsilon_4^{1+\omega} + \| \log \epsilon_4 \| \right) \Phi d\epsilon_1 d\epsilon_2 d\epsilon_3$$

$$\leq C \int \int \int_{\{\epsilon_1 \geq \epsilon_2\}} (1 + \epsilon_1)^{-\gamma} (1 + \epsilon_2)^{-\gamma} \left( 1 + \epsilon_1^{1+\omega} + \| \log \epsilon_1 \| \right) \sqrt{\epsilon_2} d\epsilon_1 d\epsilon_2$$

$$\leq C,$$

where in the estimate of $I_3$ we have used that $\epsilon_4 \leq 2\epsilon_1$.

In order to conclude the proof of (6.4) we need to use a symmetrization argument. We will use that (cf. [3], Theorem 3.4):

$$\partial_t f_1 = \frac{8\pi^2}{\sqrt{2}} \int \int_{D(\epsilon_1)} W \left[ (1 + f_1)(1 + f_2) f_3 f_4 \right.\left. - (1 + f_3)(1 + f_4) f_1 f_2 \right] d\epsilon_3 d\epsilon_4, \ a.e. \ t \in [T_1, T_2].$$

Differentiating (6.1) and using the conservation of mass, we obtain the following:

$$\partial_t \left( S [f] \right) = \int \int \int \log \left( \frac{1 + f_1}{f_1} \right) \Phi$$

$$\times \left[ (1 + f_1)(1 + f_2) f_3 f_4 - (1 + f_3)(1 + f_4) f_1 f_2 \right] d\epsilon_1 d\epsilon_3 d\epsilon_4$$

$$= \iint \log \left( \frac{1 + f_1}{f_1} \right) (1 + f_1)(1 + f_2)(1 + f_3)(1 + f_4) \left[ Q_{3,4} - Q_{1,2} \right] \Phi d\epsilon_1 d\epsilon_3 d\epsilon_4.$$
We now claim that for any function $f \in L^\infty (\mathbb{R}^+ : (1 + \epsilon)^\gamma)$ satisfying (6.15) the following identity holds:

$$J_1 = J_2,$$

where:

$$J_1 = \int \int \int \log \left( \frac{1 + f_1}{f_1} \right) (1 + f_1) (1 + f_2) (1 + f_3) (1 + f_4) \times \left[ Q_{3,4} - Q_{1,2} \right] \Phi d\epsilon_1 d\epsilon_3 d\epsilon_4$$

$$J_2 = \frac{1}{4} \int \int \int [ \log (Q_{3,4}) - \log (Q_{1,2}) ] [ Q_{3,4} - Q_{1,2} ] (1 + f_1) (1 + f_2) \times (1 + f_3) (1 + f_4) \Phi \delta (\epsilon_1 + \epsilon_2 - \epsilon_3 - \epsilon_4) d\epsilon_1 d\epsilon_2 d\epsilon_3 d\epsilon_4.$$

In order to prove (6.21) suppose first that $f \in L^\infty (\mathbb{R}^+ : (1 + \epsilon)^\gamma) \cap C (\mathbb{R}^+)$ satisfies (6.15). Then:

$$J_1 = \frac{1}{4} \int \int \int [ \log (Q_{3,4}) - \log (Q_{1,2}) ] [ Q_{3,4} - Q_{1,2} ] (1 + f_1) (1 + f_2) \times (1 + f_3) (1 + f_4) \Phi \delta (\epsilon_1 + \epsilon_2 - \epsilon_3 - \epsilon_4) d\epsilon_1 d\epsilon_2 d\epsilon_3 d\epsilon_4$$

$$= J_2$$

whence (6.21) holds for continuous functions. For arbitrary functions $f \in L^\infty (\mathbb{R}^+ : (1 + \epsilon)^\gamma)$ satisfying (6.15) we can obtain (6.21) approximating $f$ by means of a sequence of continuous function $f_n$ converging to $f$ at almost every $t \in [T_1, T_2]$.

7. Reformulation of the Criticality Condition: A Technical Lemma

We now prove an auxiliary result that reformulates the conditions in Proposition 3.1 in a form that only depends on the values of the equilibrium distributions for values of $\epsilon \geq R > 0$, with $R$ small. We define a class of auxiliary functions:

$$f_s (\epsilon; \alpha, \beta) = \frac{1}{\exp (\beta (\epsilon + \alpha)) - 1}, \quad \epsilon > -\alpha, \quad \beta > 0, \quad \alpha \in \mathbb{R}. \quad (7.1)$$

The following result holds:

**Proposition 7.1.** Given $E_* > 0$, and $\delta > 0$ there exist $R_0 (E_*, \delta) > 0$, $L_0 (E_*, \delta) > 0$ such that, if $f_s$ is one of the functions in (7.1), $0 \leq R \leq R_0 (E_*, \delta)$, $L \geq L_0 (E_*, \delta)$, $\alpha \geq -\frac{R}{2}$ and

$$E = 4\pi \int_R^L f_s (\epsilon; \alpha, \beta) \sqrt{2\epsilon^3} d\epsilon, \quad E \leq E_*$$

then:

$$4\pi \int_R^L f_s (\epsilon; \alpha, \beta) \sqrt{2\epsilon} d\epsilon \leq \frac{\zeta \left( \frac{3}{2} \right)}{\zeta \left( \frac{5}{2} \right)} \left( \frac{4\pi}{3} \right)^{\frac{3}{2}} E^{\frac{3}{2}} + \delta. \quad (7.2)$$
Proof. We will assume in all the following that $R \leq 1$, $L \geq 2$. Suppose that $E \leq E_*$. We define a family of functions function $\beta_{E,R,L} : \left[ -\frac{R}{2}, \infty \right) \to \mathbb{R}^+$ by means of the relation:

$$E = 4\pi \int_R^L f_s(\epsilon; \alpha, \beta_{E,R,L}(\alpha)) \sqrt{2\epsilon^3} d\epsilon.$$  

Since the functions $f_s(\epsilon; \alpha, \beta)$ are strictly decreasing with respect to $\beta$ and, for any given $\alpha \geq -\frac{R}{2}$ we have:

$$4\pi \lim_{\beta \to 0} \int_R^L f_s(\epsilon; \alpha, \beta) \sqrt{2\epsilon^3} d\epsilon = \infty$$

$$4\pi \lim_{\beta \to \infty} \int_R^L f_s(\epsilon; \alpha, \beta) \sqrt{2\epsilon^3} d\epsilon = 0$$

it follows that the function $\beta_{E,R,L}$ is well defined. We now define the functions $M_{E,R,L} : \left[ -\frac{R}{2}, \infty \right) \to \mathbb{R}^+$ as:

$$M_{E,R,L}(\alpha) = 4\pi \int_R^L f_s(\epsilon; \alpha, \beta_{E,R,L}(\alpha)) \sqrt{2\epsilon} d\epsilon$$

We now claim that

$$\frac{dM_{E,R,L}(\alpha)}{d\alpha} < 0 \quad (7.3)$$

for $\alpha \in \left[ -\frac{R}{2}, \infty \right)$. Indeed, differentiating $M_{E,R,L}$ we obtain

$$\frac{dM_{E,R,L}(\alpha)}{d\alpha} = \frac{\Delta_1(\alpha)}{\Delta_2(\alpha)},$$

where:

$$\Delta_1(\alpha) = 8\pi \int_R^L dx \int_R^L dy \frac{e^{\beta(x+\alpha)} e^{\beta(y+\alpha)}}{(e^{\beta(x+\alpha)} - 1)^2 (e^{\beta(y+\alpha)} - 1)^2}$$

$$\times \left[ \sqrt{xy^3} (x + \alpha) - \sqrt{yx^3} (x + \alpha) \right]$$

$$\Delta_2(\alpha) = \int_R^L dx \frac{e^{\beta(x+\alpha)} \sqrt{2x^3} (x + \alpha)}{(e^{\beta(x+\alpha)} - 1)^2} > 0.$$  

Symmetrizing the variables $x, y$ in $\Delta_1(\alpha)$ we obtain:

$$\Delta_1(\alpha) = -8\pi \int_R^L dx \int_R^L dy \frac{e^{\beta(x+\alpha)} e^{\beta(y+\alpha)} \sqrt{xy} (x - y)^2}{(e^{\beta(x+\alpha)} - 1)^2 (e^{\beta(y+\alpha)} - 1)^2} < 0$$

whence $(7.3)$ follows. Therefore:

$$M_{E,R,L}(\alpha) \leq M_{E,R,L} \left( -\frac{R}{2} \right) = 4\pi \int_R^{\infty} f_s(\epsilon; -\frac{R}{2}, \beta_{E,R,L} \left( -\frac{R}{2} \right)) \sqrt{2\epsilon} d\epsilon,$$  

where $\beta_{E,R,L} \left( -\frac{R}{2} \right)$ satisfies:

$$E = 4\pi \int_R^L f_s(\epsilon; -\frac{R}{2}, \beta_{E,R,L} \left( -\frac{R}{2} \right)) \sqrt{2\epsilon^3} d\epsilon.$$  

(7.5)
Then, since $R \leq 1$, $L \geq 2$:

$$E \geq 4\pi \int_{1}^{2} f_s \left( \epsilon; \frac{R}{2}, \beta_{E,R,L} \left( -\frac{R}{2} \right) \right) \sqrt{2\epsilon^3}d\epsilon > \frac{4\pi}{e^{2\beta_{E,R,L}(\frac{\epsilon}{\epsilon})}} \int_{1}^{2} \frac{\sqrt{2\epsilon^3}d\epsilon}{\epsilon}.$$  

(7.6)

It then follows from the fact that $E \leq E_*$ that there exists $\beta_* = \beta_*(E_*) > 0$ such that:

$$\beta_{E,R,L} \left( -\frac{R}{2} \right) \geq \beta_*.$$  

(7.7)

Using (7.7) it follows that, for any $\epsilon > 0$, there exists $L_0 = L_0 (E_*, \epsilon_0) > 0$ such that, if $L \geq L_0$:

$$4\pi \int_{L}^{\infty} f_s \left( \epsilon; \frac{R}{2}, \beta_{E,R,L} \left( -\frac{R}{2} \right) \right) \sqrt{2\epsilon^3}d\epsilon < \epsilon_0.$$  

(7.8)

We define the functions:

$$\Phi_R (\beta) = 4\pi \int_{R}^{\infty} f_s \left( \epsilon; \frac{R}{2}, \beta \right) \sqrt{2\epsilon^3}d\epsilon.$$  

(7.9)

We define $\tilde{E}$ by means of:

$$\tilde{E} = E + 4\pi \int_{L}^{\infty} f_s \left( \epsilon; \frac{R}{2}, \beta_{E,R,L} \left( -\frac{R}{2} \right) \right) \sqrt{2\epsilon^3}d\epsilon.$$  

Using (7.8) we obtain $E \leq \tilde{E} \leq E + \epsilon_0$. Notice that due to (7.5) we have $\Phi_R (\beta_{E,R,L} \left( -\frac{R}{2} \right)) = \tilde{E}$.

We now claim that there exists $\epsilon_1 > 0$ depending only on $E_*$, $\delta$ such that if $E \leq \epsilon_1$ and $\alpha \geq -\frac{R}{2}$ we have $M_{E,R,L} (\alpha) \leq \delta$. Indeed, (7.6) implies that $\beta_{E,R,L} \left( -\frac{R}{2} \right)$ can be made arbitrarily large if $\epsilon_1$ is small. Then (7.1) and (7.4) implies that $M_{E,R,L} (\alpha)$ can be made small due to Lebesgue’s dominated convergence Theorem. Then (7.2) would follow in this case. We remark that $\epsilon_1$ is independent on $R$.

We will assume then in the following that $E > \epsilon_1$. We claim that there exists $\beta^* = \beta^* (E_*, \epsilon_1)$, such that $\beta_{E,R,L} \left( -\frac{R}{2} \right) \leq \beta^*$. Indeed, we can estimate $\Phi_R (\beta)$ as:

$$\Phi_R (\beta) \leq 4\pi \int_{R}^{\infty} \sqrt{2 \left( \epsilon + \frac{R}{2} \right)^3} \frac{d\epsilon}{(e^{\beta \epsilon} - 1)} \leq 8\pi \int_{0}^{\infty} \sqrt{\epsilon^3} \frac{d\epsilon}{(e^{\beta \epsilon} - 1)}$$

and the right-hand side of this formula converges to zero as $\beta \to \infty$ due to Lebesgue’s dominated convergence Theorem. Then, $\beta_{E,R,L} \left( -\frac{R}{2} \right) \leq \beta^* = \beta^* (E_*, \epsilon_1)$ if $E \geq \epsilon_1 > 0$. We now claim that the functions $\Phi_R (\beta)$ converge uniformly in the interval $[\beta_*, \beta^*]$ as $R \to 0$ to the function:

$$\Phi_0 (\beta) = 4\pi \int_{0}^{\infty} f_s (\epsilon; 0, \beta) \sqrt{2\epsilon^3}d\epsilon = 4\pi \int_{0}^{\infty} \frac{\sqrt{2\epsilon^3}}{e^{\beta \epsilon} - 1}d\epsilon.$$  

(7.10)

Moreover, we have also uniform convergence in the interval $[\beta_*, \beta^*]$ of the derivatives $\Phi'_R (\beta)$ to $\Phi'_0 (\beta)$ as $R \to 0$. 

Indeed, this just follows from the inequalities:

\[
|\Phi_R(\beta) - \Phi_0(\beta)| \leq C \int_{\frac{R}{2}}^{\infty} \frac{\sqrt{(\epsilon + \frac{R}{2})^3} - \sqrt{\epsilon^3}}{\epsilon} e^{-\beta_\epsilon \epsilon} d\epsilon + C \int_{0}^{\frac{R}{2}} \sqrt{\epsilon} d\epsilon
\]

\[
|\Phi'_R(\beta) - \Phi'_0(\beta)| \leq C \int_{\frac{R}{2}}^{\infty} \frac{\sqrt{(\epsilon + \frac{R}{2})^3} - \sqrt{\epsilon^3}}{\epsilon} e^{-\beta_\epsilon \epsilon} d\epsilon + C \int_{0}^{\frac{R}{2}} \sqrt{\epsilon} d\epsilon.
\]

Since \( \Phi'_0(\beta) \) is strictly negative for \( \beta \in [\beta_*, \beta^*] \) we then obtain that, if \( E \geq \epsilon_1 \), \( \beta_{E,R,L}(\frac{-R}{2}) \) satisfies:

\[
|\beta_{E,R,L}(\frac{-R}{2}) - \bar{\beta}(E)| \leq C\epsilon_0 \quad (7.11)
\]

if \( R \) is sufficiently small, where \( \bar{\beta}(E) \) is the unique solution of:

\[
\Phi_0(\bar{\beta}(E)) = E.
\]

Similar computations yield the uniform convergence in the interval \( \beta \in [\beta_*, \beta^*] \) of the functions \( \Psi_R(\beta) \) defined by means of:

\[
\Psi_R(\beta) = 4\pi \int_{R}^{\infty} f_s(\epsilon; -\frac{R}{2}, \beta) \sqrt{2\epsilon} d\epsilon
\]

to:

\[
\Psi_0(\beta) = 4\pi \int_{0}^{\infty} \frac{\sqrt{2\epsilon}}{(e^{\beta\epsilon} - 1)} d\epsilon \quad (7.12)
\]

if \( E \geq \epsilon_1 \). Using (7.4) we can write:

\[
M_{E,R,L}(\frac{-R}{2}) = \left[ \Psi_R(\beta_{E,R,L}(\frac{-R}{2})) - \Psi_0(\beta_{E,R,L}(\frac{-R}{2})) \right] + \Psi_0(\beta_{E,R,L}(\frac{-R}{2})). \quad (7.13)
\]

Due to (7.11) and the uniform convergence of the functions \( \Psi_R \) to \( \Psi_0 \) stated above, it follows that the term between brackets in (7.13) can be made arbitrarily small if \( R \) is small enough. On the other hand, using again (7.11) we can make \( \Psi_0(\beta_{E,R,L}(\frac{-R}{2})) \) arbitrarily close to \( \Psi_0(\bar{\beta}(E)) \) if \( \epsilon_0 \) is small. Therefore, if \( R \) is small we obtain:

\[
M_{E,R,L}(\frac{-R}{2}) \leq \Psi_0(\bar{\beta}(E)) + \delta. \quad (7.14)
\]

Using the definitions of \( \Phi_0 \) and \( \Psi_0 \) in (7.10), (7.12) as well as Proposition 3.1 we have:

\[
\Psi_0(\bar{\beta}(E)) \leq \frac{\zeta(\frac{3}{2})}{\left(\zeta(\frac{5}{2})\right)^{\frac{3}{5}}} \left(\frac{4\pi}{3}\right)^{\frac{3}{5}} (\Phi_0(\bar{\beta}(E)))^{\frac{3}{5}} = \frac{\zeta(\frac{3}{2})}{\left(\zeta(\frac{5}{2})\right)^{\frac{3}{5}}} \left(\frac{4\pi}{3}\right)^{\frac{3}{5}} (E)^{\frac{3}{5}}.
\]

Combining this estimate with (7.14) the result follows. \( \square \)
We will prove now that if the solutions of (1.7) are globally bounded and (3.7) holds, the corresponding functions $g(t, \cdot)$ would have a significant amount of mass in the regions where $\epsilon$ is small. The main result of this Section is the following.

**Proposition 8.1.** Suppose that $f_0$, $f$ are as in Theorem 3.3. Let us assume that $T_{\text{max}} = \infty$. Then, there exists $m_\ast > 0$ and $\rho > 0$, both of them depending only on $M$, $E$ such that, for any $0 < R < \rho$ there exists a sequence $\{t_n\}$ with $t_n \to \infty$ as $n \to \infty$ such that:

$$
\int_0^R g(t_n, \epsilon) \, d\epsilon = 4\pi \int_0^R \sqrt{2\epsilon} f(t_n, \epsilon) \, d\epsilon \geq m_\ast
$$

for any $n$.

In order to prove Proposition 8.1 we need several Lemmas. We begin deriving an estimate for the number of particles with large energy.

**Lemma 8.2.** Suppose that $f_0$ and $f$ are as in Theorem 3.3. Then, for any $\epsilon_0 > 0$, there exists $L = L(E, \epsilon_0)$ such that

$$
\int_0^L g(t, \epsilon) \, d\epsilon = 4\pi \int_0^L \sqrt{2\epsilon} f(t, \epsilon) \, d\epsilon \geq M - \epsilon_0
$$

for $t \in [0, T_{\text{max}}]$.

*Proof.* It is just a consequence from the conservation of energy $E$ as well as the inequality:

$$
\int_L^\infty g(t, \epsilon) \, d\epsilon \leq \frac{1}{L} \int_L^\infty g(t, \epsilon) \, \epsilon \, d\epsilon \leq \frac{E}{L}.
$$

Choosing $L \geq \frac{E}{\epsilon_0}$ the result follows. □

We define the following auxiliary function:

$$
Q(t, \epsilon) = \frac{f(t, \epsilon)}{1 + f(t, \epsilon)}.
$$

Then:

$$
f(t, \epsilon) = \frac{Q(t, \epsilon)}{1 - Q(t, \epsilon)}.
$$

(8.2)

Notice that:

$$
0 \leq Q(t, \epsilon) \leq 1, \quad Q(t, \epsilon) \leq f(t, \epsilon), \quad \epsilon \geq 0, \quad t \in [0, T_{\text{max}}].
$$

(8.3)

Then:

$$
4\pi \int_L^\infty \sqrt{2\epsilon} f(t, \epsilon) \, d\epsilon \leq \epsilon_0,
$$
On the Blow Up and Condensation of Supercritical Solutions

355

with $L = L(\varepsilon, \varepsilon_0)$ as in Lemma 8.2. Moreover

$$4\pi \int_0^\infty \sqrt{2\varepsilon}Q(t, \varepsilon) d\varepsilon \leq M, \quad 4\pi \int_0^\infty \sqrt{2\varepsilon^3}Q(t, \varepsilon) d\varepsilon \leq E.$$  (8.4)

We define also:

$$\Psi(s) = s \log(1 + s).$$  (8.5)

We will use the following concept of weak convergence.

**Definition 8.3.** We say that a sequence $\{Q_n\} \subset L^\infty(\mathbb{R}^+)$ converges weakly to $Q_*$, and we will write in this case $Q_n \rightharpoonup Q_*$ iff:

$$\lim_{n \to \infty} \int_{\mathbb{R}^+} Q_n \varphi d\varepsilon = \int_{\mathbb{R}^+} Q_* \varphi d\varepsilon$$  (8.6)

for any test function $\varphi \in C_0[0, \infty)$.

**Remark 8.4.** If the sequence of functions $\{Q_n\}$ satisfies $0 \leq Q_n \leq 1$, we can apply a density argument to show that (8.6) holds for any $\varphi \in L^1(0, \infty)$.

We have the following result:

**Lemma 8.5.** Suppose that $f_0, f$ are as in Proposition 8.1. There exists a sequence $\{t_n\}$, $t_n \to \infty$ as $n \to \infty$ such that:

$$\int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} f(t_n, \varepsilon_1) f(t_n, \varepsilon_2) \Psi \left( \frac{Q(t_n, \varepsilon_3)Q(t_n, \varepsilon_4)}{Q(t_n, \varepsilon_1)Q(t_n, \varepsilon_2)} - 1 \right) \Phi d\varepsilon_1 d\varepsilon_2 d\varepsilon_3 \to 0$$  (8.7)

as $n \to \infty$, where $\varepsilon_4 = \varepsilon_1 + \varepsilon_2 - \varepsilon_3$. Moreover:

$$Q(t_n, \cdot) \rightharpoonup Q_*(\cdot) \quad \text{as} \quad n \to \infty$$  (8.8)

where $Q_* \in L^\infty(\mathbb{R}^+)$ and $0 \leq Q_*(\varepsilon) \leq 1, \quad \varepsilon \geq 0$.

**Proof.** Notice that (6.2) yields:

$$D[f] \geq \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} \int_{\mathbb{R}^+} f(\varepsilon_1) f(\varepsilon_2) \Psi \left( \frac{Q(\varepsilon_3)Q(\varepsilon_4)}{Q(\varepsilon_1)Q(\varepsilon_2)} - 1 \right) \Phi d\varepsilon_1 d\varepsilon_2 d\varepsilon_3.$$  (8.9)

Due to (6.3) we have $|S[f](T_2)| + |S[f](T_1)| \leq 2C(E, M)$. Then, since $T_{\text{max}} = \infty$, and $|S[f](T_2)| < \infty$, we can use (6.4) to obtain:

$$\int_{T_1}^\infty D[f(\cdot, t)] dt < \infty.$$  (8.10)

Therefore, there exists a sequence $\{t_n\}$, $t_n \to \infty$ such that $D[f(\cdot, t_n)] \to 0$ as $n \to \infty$. Using then (8.9) we obtain (8.7). Using (8.3) and classical compactness results for measures in the weak topology, we can then extract a subsequence of $\{t_n\}$ (which will be denoted in the same way) for which (8.8) holds. □

**Lemma 8.6.** Suppose that $f_0, f$ are as in Lemma 8.5. Let us assume that $Q_* = 0$ in (8.8) for $0 \leq R_1 \leq \varepsilon \leq R_2 < \infty$. Then:

$$\int_{R_1}^{R_2} Q(t_n, \varepsilon) \sqrt{\varepsilon} d\varepsilon \to 0, \quad \int_{R_1}^{R_2} f(t_n, \varepsilon) \sqrt{\varepsilon} d\varepsilon \to 0 \quad \text{as} \quad n \to \infty.$$  (8.10)
Proof. Choosing the test function \( \varphi \) such that \( \varphi (\epsilon) = 1 \) for \( \epsilon \in [R_1, R_2] \) and \( \varphi (\epsilon) = 0 \) for \( \epsilon \notin [R_1, R_2] \) (cf. Remark 8.4), we obtain, using the nonnegativity of \( Q \), that for \( n \) large enough:

\[
\int_{R_1}^{R_2} Q(t_n, \epsilon) \sqrt{\epsilon} d\epsilon \to 0 \quad \text{as} \quad n \to \infty.
\]

In order to prove the second formula in (8.10) we define the set:

\[
U_n (R_1, R_2) = \left\{ R_1 \leq \epsilon \leq R_2 : Q(t_n, \epsilon) \geq \frac{1}{2} \right\}.
\]

Then:

\[
\int_{R_1}^{R_2} Q(t_n, \epsilon) f(t_n, \epsilon) \Psi \left( \frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} - 1 \right) \Phi d\epsilon_1 d\epsilon_2 d\epsilon_3
\]

\[
\int_{R_1}^{R_2} Q(t_n, \epsilon) f(t_n, \epsilon_1) f(t_n, \epsilon_2) \Psi \left( \frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} - 1 \right) \Phi d\epsilon_1 d\epsilon_2 d\epsilon_3
\]

\[
\int_{R_1}^{R_2} Q(t_n, \epsilon) f(t_n, \epsilon_1) f(t_n, \epsilon_2) \Psi \left( \frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} - 1 \right) \Phi d\epsilon_1 d\epsilon_2 d\epsilon_3
\]

Using that \( Q(t_n, \epsilon_4) \leq 1, Q(t_n, \epsilon_j) \geq \frac{1}{2} \) if \( \epsilon_j \in U_n (R_1, R_2) \) for some \( j = 1, 2 \), as well as the fact that the function \( \Psi (s) \) is decreasing for \( s \in (-1, -\frac{1}{2}) \) we obtain:

\[
\int_{R_1}^{R_2} Q(t_n, \epsilon) f(t_n, \epsilon_1) f(t_n, \epsilon_2) \Psi \left( \frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} - 1 \right) \Phi d\epsilon_1 d\epsilon_2 d\epsilon_3
\]

Due to the first formula in (8.10) we have that

\[
\left\| Q(t_n, \epsilon_3) > \frac{1}{8} \right\| \cap \left\{ \frac{R_1}{2} \leq \epsilon_3 \leq \frac{3R_1}{2} \right\} \to 0
\]

as \( n \to \infty \). Then:

\[
\lim_{n \to \infty} \int_{R_1}^{R_2} Q(t_n, \epsilon_3) d\epsilon_3 = \int_{R_1}^{R_2} \frac{R_1}{2} \leq \epsilon_3 \leq \frac{3R_1}{2} d\epsilon_3 = R_1
\]
Therefore, using (8.7):
\[
\lim_{n \to \infty} \int_{U_n(R_1, R_2)} f(t_n, \epsilon) \, d\epsilon = 0.
\]

We then have, taking into account (8.2) and the first limit in (8.10):
\[
\lim_{n \to \infty} \int_{R} f(t_n, \epsilon) \sqrt{\epsilon} \, d\epsilon = \lim_{n \to \infty} \int_{[R, \infty) \setminus U_n(R_1, R_2)} f(t_n, \epsilon) \sqrt{\epsilon} \, d\epsilon
\]
\[
+ \lim_{n \to \infty} \int_{U_n(R_1, R_2)} f(t_n, \epsilon) \, d\epsilon \leq 2 \lim_{n \to \infty} \int_{[R, \infty) \setminus U_n(R_1, R_2)} Q(t_n, \epsilon) \sqrt{\epsilon} \, d\epsilon = 0.
\]

\[\square\]

**Lemma 8.7.** Suppose that \(f_0, f\) are as in Lemma 8.5. Let us assume that \(Q_* \neq 0\) for \(\epsilon \geq R_1\) in (8.8). Suppose that \(0 < R_1 \leq 1\). Then:
\[
\int_{R_1}^{\infty} \int_{R_1}^{\infty} \int_{R_1}^{\infty} |Q(t_n, \epsilon_3) Q(t_n, \epsilon_4) - Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)| \, d\epsilon_1 \, d\epsilon_2 \, d\epsilon_3 \to 0 \quad \text{as} \, n \to \infty.
\]

(8.11)

**Proof.** Using (8.3) we obtain:
\[
\int_{R^+} \int_{R^+} \int_{R^+} Q(t_n, \epsilon_1) Q(t_n, \epsilon_2) \Psi \left( \frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} - 1 \right) \, \Phi \, d\epsilon_1 \, d\epsilon_2 \, d\epsilon_3
\]
\[
\leq \int_{R^+} \int_{R^+} \int_{R^+} f(t_n, \epsilon_1) f(t_n, \epsilon_2) \Psi \left( \frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} - 1 \right) \, \Phi \, d\epsilon_1 \, d\epsilon_2 \, d\epsilon_3.
\]

Then:
\[
\int_{R^+} \int_{R^+} \int_{R^+} f(t_n, \epsilon_1) f(t_n, \epsilon_2) \Psi \left( \frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} - 1 \right) \, \Phi \, d\epsilon_1 \, d\epsilon_2 \, d\epsilon_3
\]
\[
\geq \int_{R_1} \int_{R_1} \int_{R_1}^{3R_1} Q(t_n, \epsilon_1) Q(t_n, \epsilon_2) \Psi \left( \frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} - 1 \right) \, \Phi \, d\epsilon_1 \, d\epsilon_2 \, d\epsilon_3
\]
\[
\geq \sqrt{\frac{R_1}{2}} \int_{R_1} \int_{R_1} \int_{R_1}^{3R_1} Q(t_n, \epsilon_1) Q(t_n, \epsilon_2) \Psi \left( \frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} - 1 \right) \, d\epsilon_1 \, d\epsilon_2 \, d\epsilon_3.
\]

We define a convex function \(\overline{\Psi}(s)\) as:
\[
\overline{\Psi}(s) = \Psi(s) \quad \text{if} \quad s \geq 0, \quad \text{and} \quad \overline{\Psi}(s) = \overline{\Psi}(-s).
\]

Notice that \(\overline{\Psi}(s)\) is bounded as \(C|s|\) for large \(|s|\). Using Jensen’s inequality we obtain:
\[
R_1 \left( \int_{R_1}^\infty Q(t_n, \epsilon) \, d\epsilon \right)^2 \sqrt{\frac{R_1}{2}} \overline{\Psi}
\]
\[
\times \left( \int_{R_1}^\infty \int_{R_1}^\infty \int_{R_1}^{3R_1} |Q(t_n, \epsilon_3) Q(t_n, \epsilon_4) - Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)| \, d\epsilon_1 \, d\epsilon_2 \, d\epsilon_3 \right)
\]
\[
\leq \int_{R^+} \int_{R^+} \int_{R^+} f(t_n, \epsilon_1) f(t_n, \epsilon_2) \Psi \left( \frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} - 1 \right) \, \Phi \, d\epsilon_1 \, d\epsilon_2 \, d\epsilon_3.
\]
Taking into account (8.7) as well as the fact that \( \tilde{\Psi}(s) \) vanishes only for \( s = 0 \) we obtain (8.11). \( \square \)

**Lemma 8.8.** Given \( 0 < R_1 < R_2 < \infty \), suppose that \( f_0 \) as in the statement of Proposition 8.1, let \( \{t_n\} \) as in Lemma 8.5. Suppose that \( Q_0 \neq 0 \) in the interval \([R_1, R_2]\). Then \( Q_0(\epsilon) = \exp(-\beta_0(\epsilon + \alpha)) \) for \( \epsilon \in [R_1, R_2] \) with \( \beta_0 > 0 \) and \( \alpha \geq -R_1 \). Moreover, there exists a subsequence of \( \{t_n\} \) which will be denoted with the same indexes such that:

\[
Q(t_n, \cdot) \to Q_0(\cdot) \text{ in } L^1(R_1, R_2) \text{ as } n \to \infty. \tag{8.12}
\]

**Proof.** Let us define:

\[
R_* = \sup \left\{ r \in [R_1, R_2]: \int_{R_1}^{r} Q_* d\epsilon = 0 \right\}. \tag{8.13}
\]

Since \( Q_* \neq 0 \) in the interval \([R_1, R_2]\) we have \( R_* < R_2 \). We then define also:

\[
Q_n(\epsilon_3) = \int_{\bar{R}}^{\infty} \int_{\bar{R}}^{\infty} |Q(t_n, \epsilon_3) Q(t_n, \epsilon_1 + \epsilon_2 - \epsilon_3) - Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)| d\epsilon_1 d\epsilon_2,
\]

where \( \bar{R} = \max\{R_1, \theta R_*\} \), where \( \theta < 1 \) is very close to one, to be determined later.

Using Lemma 8.7, and more precisely (8.11), with \( R_1 = \bar{R} \), it follows that there exists a set \( \mathcal{V} \subset \left[\frac{\bar{R}}{2}, \frac{3\bar{R}}{2}\right] \) with measure \( |\mathcal{V}| = \bar{R} \) and a subsequence of \( \{t_n\} \), which will be labelled with the same indexes, such that:

\[
Q_n(\epsilon_3) \to 0, \ n \to \infty \text{ for any } \epsilon_3 \in \mathcal{V}. \tag{8.14}
\]

The definition of \( R_* \) and the assumptions of the Lemma imply the existence of a \( \delta > 0 \) such that

\[
\int_{R_* + \delta}^{R_2} Q_0(\epsilon) d\epsilon > 0. \tag{8.15}
\]

We now claim that there exists \( \epsilon_* \in \mathcal{V} \cap \{R_* \leq \epsilon \leq R_* + \delta\} \) and a subsequence of \( \{t_n\} \), labelled with the same indexes such that:

\[
\lim_{n \to \infty} Q(t_n, \epsilon_*) = \eta > 0. \tag{8.16}
\]

Indeed, otherwise we would have \( \lim_{n \to \infty} Q(\epsilon, t_n) = 0 \) for any \( \epsilon \in \mathcal{V} \cap \{R_* \leq \epsilon \leq R_* + \delta\} \). Lebesgue’s dominated convergence theorem, combined with (8.3) would imply that \( Q_0(\epsilon) = 0 \) a.e. \( \epsilon \in \left[\frac{\bar{R}}{2}, R_* + \delta\right] \), but this would contradict the definition of \( R_* \) in (8.13).

Therefore:

\[
\int_{\bar{R}}^{\infty} \int_{\bar{R}}^{\infty} |Q(t_n, \epsilon_*) Q(t_n, \epsilon_1 + \epsilon_2 - \epsilon_*) - Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)| d\epsilon_1 d\epsilon_2 \to 0 \quad \text{as } n \to \infty.
\]

Writing \( x = \epsilon_1 - \epsilon_*, \ y = \epsilon_2 - \epsilon_* \) and \( H_n(x) = Q(t_n, \epsilon_0 + x) \) it then follows that:

\[
\int_{\bar{R} - \epsilon_*}^{\infty} \int_{\bar{R} - \epsilon_*}^{\infty} |Q(t_n, \epsilon_0) H_n(x + y) - H_n(x) H_n(y)| dxdy \to 0 \quad \text{as } n \to \infty. \tag{8.17}
\]
We define:

\[ G_n(x) = \int_x^\infty H_n(\xi) \, d\xi. \] (8.18)

Note that this integral is finite for any \( n \), due to (8.3). Moreover, they are uniformly bounded by a constant \( C = C(M, R_1) < \infty \). Then:

\[
\int_{\tilde{R} - \epsilon_*}^\infty |Q(t_n, \epsilon_*) \, G_n(x) - H_n(x) \, G_n(0)| \, dx
\]

\[
\leq \int_{\tilde{R} - \epsilon_*}^\infty \int_0^\infty |Q(t_n, \epsilon_*) \, H_n(x + y) - H_n(x) \, H_n(y)| \, dy \, dx
\]

\[
\leq \int_{\tilde{R} - \epsilon_*}^\infty \int_{\tilde{R} - \epsilon_*}^\infty |Q(t_n, \epsilon_*) \, H_n(x + y) - H_n(x) \, H_n(y)| \, dy \, dx \to 0
\]

where we use that \( \epsilon_* \geq R_* \geq \tilde{R} \).

Defining:

\[ \tilde{\lambda}_n(x) = Q(t_n, \epsilon_*) \, G_n(x) - H_n(x) \, G_n(0) \] (8.19)

it then follows that:

\[ \int_{\tilde{R} - \epsilon_*}^\infty |\tilde{\lambda}_n(x)| \, dx \to 0 \quad \text{as} \quad n \to \infty. \] (8.20)

Due to (8.3) we have \( G_n \in W^{1,\infty} (R_* - \epsilon_*, \infty) \). Then (8.19) implies:

\[ \tilde{\lambda}_n(x) = Q(t_n, \epsilon_*) \, G_n(x) + G_n(0) \, G'_n(x), \quad \text{a.e.} \ x \geq \tilde{R} - \epsilon_* . \] (8.21)

Notice also that the weak convergence of the sequence \( Q(\cdot, t_n) \) implies that \( G_n(0) \to \int_\epsilon^\infty Q_*(\epsilon) \, d\epsilon \) as \( n \to \infty \). Due to (8.15) we have \( \int_\epsilon^\infty Q_*(\epsilon) \, d\epsilon > 0 \). Let us write \( \lambda_n(x) = \tilde{\lambda}_n(x) / G_n(0) \), \( \beta_n = Q(t_n, \epsilon_*) / G_n(0) \). Due to (8.16), (8.20) and the fact that \( \lim_{n \to \infty} G_n(0) > 0 \), we obtain:

\[ \int_{\tilde{R} - \epsilon_*}^\infty |\lambda_n(x)| \, dx \to 0, \quad \beta_n \to \beta_* > 0 \quad \text{as} \quad n \to \infty \] (8.22)

\[ G'_n(x) + \beta_n G_n(x) = \lambda_n(x). \] (8.23)

Integrating (8.23):

\[ G_n(x) = A_n e^{-\beta_n x} + \int_x^\infty e^{-\beta_n (x-y)} \lambda_n(y) \, dy, \quad x \geq \tilde{R} - \epsilon_* \] (8.24)

for suitable constants \( A_n \in \mathbb{R} \). Due to (8.22) the integral term in (8.24) converges to zero, uniformly in the set \([0, \infty)\). Since \( G_n(0) \) is uniformly bounded it then follows that the sequence \( \{A_n\} \) is bounded. Taking a new subsequence if needed, it then follows that \( A_n \to A_* \) as \( n \to \infty \), whence:

\[ G_n(x) \to A_* e^{-\beta_* x}, \quad x \geq \tilde{R} - \epsilon_. \]

Using (8.23) we obtain that \( H_n \to A_* \beta_* e^{-\beta_* x} \) in \( L^1(\tilde{R} - \epsilon_*, \tilde{L}) \) for any \( \tilde{L} \) fixed, sufficiently large. Therefore

\[ Q(t_n, \epsilon) \to \exp(-\beta_*(\epsilon + \alpha)) \quad \text{as} \quad n \to \infty, \quad \alpha \in \mathbb{R} \] (8.25)
in $L^1(\mathcal{R}, L)$ with $L$ large. We now consider two cases. If $R_* = R_1$, (8.25) would imply (8.12). Otherwise, we choose $\theta < 1$ sufficiently close to one to have $R_1 \leq \theta R_* < R_*$. Then (8.25) would imply $Q_*(\epsilon) = \exp(-\beta_* (\epsilon + \alpha))$ and this would contradict the definition of $R_*$ in (8.13). Therefore $\mathcal{R} = R_* = R_1$. Using that $Q_*(\epsilon) \leq 1$ for $\epsilon \geq R_1$, it follows that $\alpha \geq -R_1$ and this concludes the proof. □

**Lemma 8.9.** Suppose that $f_0$ as in the statement of Proposition 8.1. Let $0 < R_1 \leq 1 < R_2 < \infty$ and $\{t_n\}$ as in Lemma 8.8. Let us write $f_*(\epsilon) = \frac{1}{\exp(\beta_*(\epsilon + \alpha)) - 1}$ where $\alpha$, $\beta_*$ are as in Lemma 8.8. Then, for a suitable subsequence of $\{t_n\}$ which will be labelled with the same indexes and for any $\delta > 0$ small:

$$f( t_n, \cdot ) \to f_*( \cdot ) \text{ in } L^1((R_1, R_2) \cap \{Q_* < 1 - 5\delta\}) \text{ as } n \to \infty$$

with $Q_*$ as in Lemma 8.8.

**Remark 8.10.** Notice that the restriction $\{Q_* < 1 - 5\delta\}$ applies only to the limit distribution $Q_*$, and not to the sequence $Q(t_n, \cdot)$.

**Proof.** Taking a subsequence if needed we can assume that the convergence $Q(t_n, \cdot) \to Q_*(\cdot)$ in Lemma 8.8 takes place for a.e. $\epsilon \in (R_1, R_2)$. Let us denote as $\mathcal{I}$ the set $\mathcal{I} = (R_1, R_2) \cap \{\epsilon; \quad Q_*(\epsilon) < 1 - 5\delta\}$. We estimate the $L^1$ norm of $f(t_n, \cdot) - f_*(\cdot)$ as follows:

$$\int_{\mathcal{I}} |f( t_n, \epsilon ) - f_*( \epsilon )| \, d\epsilon = J_{1,n} + J_{2,n}$$

$$J_{1,n} = \int_{\mathcal{I} \cap \mathcal{B}_n^1} |f( t_n, \epsilon ) - f_*( \epsilon )| \, d\epsilon$$

$$J_{2,n} = \int_{\mathcal{I} \cap \mathcal{B}_n^2} |f( t_n, \epsilon ) - f_*( \epsilon )| \, d\epsilon$$

(8.26)

$$\mathcal{B}_n = \{\epsilon > 0; \quad Q(t_n, \epsilon) \geq 1 - \delta\}.$$  

(8.27)

The sequence $J_{2,n}$ converges to zero as $n \to \infty$ due to (8.2) as well as the fact that the function $\frac{1}{(1 - Q(t_n, \epsilon))(1 - Q_*(\epsilon))}$ is bounded in the corresponding integration region.

To estimate $J_{1,n}$ we use Lemma 8.5. Then:

$$\int_{\mathcal{I} \cap \mathcal{B}_n} \int_{\mathcal{I} \cap \mathcal{B}_n} f( t_n, \epsilon_1 ) f( t_n, \epsilon_2 ) \psi \left( \frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} - 1 \right) \Phi \epsilon_3 \epsilon_1 d\epsilon_1 d\epsilon_2 \to 0$$

as $n \to \infty$.

Notice that $\Phi$ can be estimated from below uniformly in $n$ if, say,

$$R_1 \leq \epsilon_3 \leq \frac{2}{3} (\epsilon_1 + \epsilon_2).$$  

(8.29)

On the other hand, since we integrate in $\epsilon_3$ in $\mathcal{I}$ we need to ensure that the domain where (8.29) holds has an intersection with $\mathcal{I}$ whose measure can be estimated from below. This can be seen because the values of $\epsilon_1$, $\epsilon_2$ must be also in the interval $\mathcal{I}$. Notice that $\mathcal{I} = (\bar{\epsilon}, R_2)$ for some $\bar{\epsilon}$ depending on $\delta, R_1$. Therefore we obtain that the
region of integration for $\epsilon_3$ can be replaced by a set $(\bar{\epsilon}, \frac{4\bar{\epsilon}}{3})$. Notice that this set is contained in $\mathcal{I}$. Then:

$$\int_{\mathcal{I} \cap B_n} \int_{\mathcal{I} \cap B_n} \int_{(\bar{\epsilon}, \frac{4\bar{\epsilon}}{3})} f(t_n, \epsilon_1) f(t_n, \epsilon_2) \Psi \left( \frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} - 1 \right) d\epsilon_3 d\epsilon_1 d\epsilon_2 \to 0$$

as $n \to \infty$

due to the fact that we have a lower estimate for $\Phi$ independent on $n$ for $\epsilon_3 \in (\bar{\epsilon}, \frac{4\bar{\epsilon}}{3})$.

We now use the convergence of $Q(t_n, \cdot)$ to $Q_\ast(\cdot)$ in $L^1(\bar{\epsilon}, \frac{4\bar{\epsilon}}{3})$ which is a Corollary of Lemma 8.8. Egoroff’s Theorem shows that there exists a set $\mathcal{A} \subset (\bar{\epsilon}, \frac{4\bar{\epsilon}}{3})$ with a measure arbitrarily close to $\bar{\epsilon}$ where $Q(t_n, \cdot) \to Q_\ast(\cdot)$ uniformly. Then:

$$\int_{\mathcal{I} \cap B_n} \int_{\mathcal{I} \cap B_n} \int_{\mathcal{A}} f(t_n, \epsilon_1) f(t_n, \epsilon_2) \Psi \left( \frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} - 1 \right) d\epsilon_1 d\epsilon_2 d\epsilon_3 \to 0$$

as $n \to \infty$

and assuming that $n$ is sufficiently large we would have:

$$\frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} \leq \frac{(1 - 5\delta)}{(1 - \delta)^2} \leq (1 - \delta)$$

if $\delta$ is small. Then, $\Psi \left( \frac{Q(t_n, \epsilon_3) Q(t_n, \epsilon_4)}{Q(t_n, \epsilon_1) Q(t_n, \epsilon_2)} - 1 \right) \geq c_0 > 0$ independent of $n$, whence:

$$c_0 |\mathcal{A}| \left( \int_{\mathcal{I} \cap B_n} f(t_n, \epsilon) \, d\epsilon \right)^2 \to 0 \quad \text{as} \quad n \to \infty.$$

Then:

$$\int_{\mathcal{I} \cap B_n} f(t_n, \epsilon) \, d\epsilon \to 0 \quad \text{as} \quad n \to \infty. \quad (8.30)$$

On the other hand, since $Q_\ast(\epsilon) \leq (1 - 5\delta)$ for $\epsilon \in \mathcal{I}$, it follows that:

$$|\mathcal{I} \cap B_n| \to 0 \quad \text{as} \quad n \to \infty \quad (8.31)$$

due to Lebesgue’s Theorem. We can take the limit of the sequence $J_{1,n}$ as:

$$J_{1,n} \leq \int_{\mathcal{I} \cap B_n} f(t_n, \epsilon) \, d\epsilon + \int_{\mathcal{I} \cap B_n} f_\ast(\epsilon) \, d\epsilon \to 0$$

due to the fact that $f_\ast(\epsilon)$ is bounded in $\mathcal{I}$ and using (8.30), (8.31).

Proof of Proposition 8.1. Given $f_0$ as in the statement of Proposition 8.1, we have that the stationary solution $F_{BE}(\rho; \alpha, \beta, m_0)$ in Proposition 3.1 having the number of particles $M$ and energy $E$ satisfies $m_0 > 0$. We define $m_\ast = \frac{m_0}{2}$. Due to the Lemma 8.2 we can select $L > 0$ such that:

$$\int_{L}^{\infty} g(t, \epsilon) \, d\epsilon = 4\pi \int_{L}^{\infty} f(t, \epsilon) \sqrt{2\epsilon} \, d\epsilon \leq \frac{m_0}{10} \quad (8.32)$$

for any $t \in [0, T_{\max}]$. 

We now apply Lemma 8.5. Then (8.8) holds. We have now two possibilities. Suppose first that \( Q_* \equiv 0 \text{ in } [R, \infty) \). Then Lemma 8.6 with \( R_1 = \frac{R}{2} \) and \( R_2 = L \), combined with (8.32) imply that:

\[
\int_{R}^{\infty} g(t_n, \epsilon) \, d\epsilon = \int_{R}^{L} g(t_n, \epsilon) \, d\epsilon + \int_{L}^{\infty} g(t_n, \epsilon) \, d\epsilon \leq \int_{R}^{R_2} g(t_n, \epsilon) \, d\epsilon + m_0 \frac{10}{10} \leq m_0 \frac{5}{5}
\]

if \( n \) is sufficiently large. Then:

\[
\int_{0}^{R} g(t_n, \epsilon) \, d\epsilon \geq \frac{4m_0}{5} > m_*
\]

whence the result follows in this case.

Suppose now that \( Q_* \not\equiv 0 \text{ in } [R, \infty) \). We then set \( R_1 = R_2 \), \( R_2 = L \). We choose \( \delta > 0 \) small and apply Lemma 8.9 to obtain:

\[
\int_{(R, L) \cap \{Q_* < 1 - 5\delta\}} g(t_n, \epsilon) \, d\epsilon \to 4\pi \int_{(R, L) \cap \{Q_* < 1 - 5\delta\}} f_*(\epsilon) \sqrt{2\epsilon} \, d\epsilon
\]

(8.33)

\[
\int_{(R, L) \cap \{Q_* < 1 - 5\delta\}} g(t_n, \epsilon) \, d\epsilon \to 4\pi \int_{(R, L) \cap \{Q_* < 1 - 5\delta\}} f_*(\epsilon) \sqrt{2\epsilon^3} \, d\epsilon
\]

as \( n \to \infty \). (Notice that the integrations are made in the interval \((R, L)\) in spite of the fact that the convergence in Lemma 8.8 is in \( \epsilon \geq R_2 \). In particular \( \alpha \geq -\frac{R}{2} \).

We now claim that the right-hand side of (8.33) can be made smaller than \( M \) plus some small error term if \( \delta \) and \( R \) are small. Actually taking \( \delta \) much smaller than \( \frac{R}{2} \) we would obtain that \((R, L) \cap \{Q_* < 1 - 5\delta\} = (R, L)\). Then:

\[
\int_{(R, L)} g(t_n, \epsilon) \, d\epsilon \to 4\pi \int_{(R, L)} f_*(\epsilon) \sqrt{2\epsilon^3} \, d\epsilon
\]

(8.34)

We now use that \( \int_{(R, L)} g(t_n, \epsilon) \, d\epsilon \leq E \), whence:

\[
4\pi \int_{(R, L)} f_*(\epsilon) \sqrt{2\epsilon^3} \, d\epsilon \leq E.
\]

On the other hand, using (8.32) as well as the fact that \( \int g \, d\epsilon = M \) we obtain that:

\[
\int_{(0, R)} g(t_n, \epsilon) \, d\epsilon + \int_{(R, L)} g(t_n, \epsilon) \, d\epsilon \geq M - m_0 \frac{10}{10}.
\]

Using (8.34) as well as Proposition 7.1 we obtain, assuming that \( n \) is large and taking \( \delta = \frac{m_0}{10} \) in Proposition 7.1:

\[
\int_{(R, L)} g(t_n, \epsilon) \, d\epsilon \leq \frac{\zeta \left( \frac{3}{2} \right)}{\zeta \left( \frac{5}{2} \right)} \left( \frac{4\pi}{3} \right)^{\frac{3}{5}} E^{\frac{3}{5}} + \frac{m_0}{10}
\]
Using now the hypothesis (3.7) in Theorem 3.3 as well as the fact that
\[ M - \frac{\zeta(\frac{3}{2})}{(\zeta(\frac{3}{2}))^{\frac{3}{2}}} \]
\[ \left( \frac{4\pi}{3} \right)^{\frac{3}{5}} \frac{3}{5} E^{\frac{3}{5}} = m_0 \]
we obtain:
\[ \int_{(0,R)} g(t_n, \epsilon) d\epsilon \geq \left[ M - \frac{\zeta(\frac{3}{2})}{(\zeta(\frac{3}{2}))^{\frac{3}{2}}} \left( \frac{4\pi}{3} \right)^{\frac{3}{5}} E^{\frac{3}{5}} \right] - \frac{m_0}{5} = \frac{4m_0}{5} \quad (8.35) \]

if \( R \) is sufficiently small, depending only on \( E, M \). We now use Proposition 5.1 combined with (8.35) and Theorem 4.1 implies that \( f \) must become unbounded in finite time. Notice that we apply Theorem 4.1 taking as starting time \( T_1 = t_n \). The Theorem 4.1 can be applied there due to the invariant of the problem under translations in time. Note also that given a mild solution of (1.7), (1.8) defines also a mild solution in any time interval \([T_1, T_2] \subset [0, T_{\text{max}}] \). Indeed, we just need to split the integral in time and using the remaining terms as new initial data for the solution using the semigroup property of the exponential term. \( \square \)

9. End of the Proof of Theorem 3.3

End of the Proof of Theorem 3.3. It is just a consequence of Theorem 4.1, Proposition 5.1 and Proposition 8.1. Notice that the blow-up condition (4.1) can be applied starting at any time \( T \geq 0 \) and not necessarily at \( T = 0 \), due to the invariance of (1.7) under translations in time. \( \square \)

10. Finite Time Condensation

Proof of Theorem 4.2. Let \( g_0 \in \mathcal{M}_+ \left( \mathbb{R}^+; (1 + \epsilon) \right) \) be the weak solution of (2.4), (2.5) with initial data \( g_0 \), whose existence is proved in [10]. It is also proved in the same article that, when \( t \to +\infty \), \( g(t) \) converges in the sense of measures to the unique steady state \( F_{BE} \) of the family (1.9) with the same mass \( M \) and energy \( E \). Since \( M \) and \( E \) satisfy (3.7), that steady state contains a Dirac measure at the origin. We deduce that there exists \( t_n \to +\infty, \rho_n \to 0 \) and a constant \( m > 0 \) such that for all \( n \):\n\[ \int_0^{\rho_n} g(t_n, \epsilon) (\epsilon) d\epsilon \geq m. \]
It then follows that \( g(t_n, \cdot) \) satisfies:
\[ \int_0^{\rho} g(t_n, \epsilon) d\epsilon \geq K^* \rho_n^o \]

if \( n \) is sufficiently large. On the other hand, by Proposition 5.1, if \( t_n > T_1(E, M) \), \( g(t_n) \) also satisfies
\[ \int_0^R g(t_n, \epsilon) d\epsilon \geq K R^2 \quad \text{for any} \ 0 < R \leq \rho_1(E, M), \]
and then, choosing \( \nu < K \) we have:
\[ \int_0^R g_0(\epsilon) d\epsilon \geq \nu R^{3/2} \quad \text{for any} \ 0 < R \leq \rho_1(E, M). \]
Using that $t_n \to \infty$ as $n \to \infty$, we deduce that for if $n$ is sufficiently large, $g(t_n)$ satisfies condition (4.5). Therefore, since for all $t > t_n$, the function $g$ may be seen as a weak solution of (2.4), (2.5) with initial data $g(t_n)$ we deduce from Theorem 4.2 that there exists $T_0 \geq t_n$ such that property (2.6) holds. □

11. Blow-Up and Condensation for Subcritical Data

It is worth noticing that the blow-up and condensation conditions [(4.2) and (4.5) respectively] in [3] are purely local. As a consequence it is possible to find initial data with values of the particle density and the energy $(M, E)$ in the subcritical region, but on the other hand yielding blow-up in finite time or condensation. We formulate the results as the two following Theorems due to their independent interest.

**Theorem 11.1.** Given $f_0 \in L^\infty(R^+; (1+t)\gamma)$ with $\gamma > 3$. Let us denote as $M$, $E$ the numbers:

$$4\pi \int_0^\infty f_0(\epsilon) \sqrt{2}\epsilon d\epsilon = M, \quad 4\pi \int_0^\infty f_0(\epsilon) \sqrt{2}\epsilon^3 d\epsilon = E$$

Let us denote as $f \in L^\infty_{loc}([0, T_{max}]; L^\infty(R^+; (1+\epsilon)\gamma))$ the mild solution of (1.7), (1.8) in Theorem 2.3 where $T_{max}$ is the maximal existence time. There exist functions $f_0 \in L^\infty(R^+; (1+\epsilon)\gamma)$ with $\gamma > 3$ such that:

$$M < \frac{\xi \left(\frac{3}{2}\right)}{\left(\xi \left(\frac{5}{2}\right)\right)^\frac{3}{2}} \left(\frac{4\pi}{3}\right)^\frac{3}{2} E^\frac{3}{2}$$

for which $T_{max} < \infty$.

**Proof.** It is just a consequence of the fact that (4.1), (4.2) can be obtained for initial data satisfying (11.1). This can be done modifying locally $f_0$ in a region $\epsilon \leq R$, with $R$ small in order to obtain (4.1), (4.2). This can be made, as in the Proof of Proposition (2.4) in [3], changing $M$ and $E$ as little as wished. □

**Theorem 11.2.** There exists weak solutions $g$ of (2.4), (2.5) in the sense of Definition 2.4 with initial data $g_0 \in M_+ (R^+; (1+\epsilon))$ satisfying

$$4\pi \sqrt{2} \int_{R^+} g_0(\epsilon) d\epsilon = M, \quad 4\pi \sqrt{2} \int_{R^+} g_0(\epsilon) \epsilon d\epsilon = E,$$

with $M$ and $E$ like in (11.1), such that (2.6) holds for some finite $T > 0$.

**Proof.** The Proof of Theorem 11.2 is completely similar to that of Theorem 11.1 with condition (4.5) instead of (4.1), (4.2) and using $g_0$ instead of $f_0$. □
