Abstract: In order to accurately investigate the disturbance of complex distributed mass loading on surface acoustic wave (SAW) propagation characteristics, two-dimensional coupling-of-modes (2-D COM) theory and finite element method (FEM) were used to simulate the responses of SAW sensors. By using the PDE mode of FEM software, four SAW resonators with the loads in different distribution patterns were modeled. Also, we fabricated and measured a series of SAW resonators accordingly. The results showed that the 2-D COM theory combined with the finite element method was able to simulate the transverse modes of the device and the disturbance of the mass loading on the transverse mode effectively, making the simulation more accurate.

Keywords: SAW sensors; non-uniform load; 2-D COM theory; finite element method (FEM); transverse modes

1. Introduction

Coupling-of-modes (COM) theory is an effective method for the simulation of surface acoustic wave (SAW) devices [1], which is widely used in the design and optimization of SAW filters. In order to calculate the influence of waveguide effect on the response of SAW filter, Haus et al. proposed the two-dimensional coupling-of-modes (2-D COM) theory [2,3], and then the two-dimensional P-matrix model was developed by Bergmann et al. [4] Although these methods have the ability to calculate the transverse modes of the SAW, they are difficult to be used in the design and optimization of SAW devices effectively due to the complexity of modeling and calculation. In order to improve the efficiency of simulation, Hirota et al. solved the 2-D COM equation by using the finite element method (FEM) [5]. Based on this work, a new form of 2-D COM equations under biquadratic approximation was developed by Xiao et al. They used the finite element method to extract anisotropic parameters, which further improved the accuracy of the two-dimensional simulation [6].

In recent years, the SAW devices have been widely used in the field of biochemical detection [7–12]. In many cases, the target analytes adhered to the sensor’s surface usually presents complex and non-uniformly distributions, as shown in Figure 1. Therefore, to investigate the disturbance of complex distributed mass loading on the SAW propagation characteristics is necessary, which put forward higher requirements for the simulation technology. In our previous work, we used a two-dimensional segmentation method (2-D SM) combined with 1-D COM theory to calculate the sensor response under various non-uniformly distributed loads [13]. However, the 2-D SM is an approximate method which discretizes the sensitive area of the sensor, and the 1-D COM theory is unable to simulate the transverse mode of the SAW, so the accuracy of the 2-D SM still needs to be improved. What’s more,
the complexity of the two-dimensional segmentation design and the P-matrix cascading operation limit the application of the 2-D SM in different SAW devices.

![SAW sensors with non-uniform load](image)

**Figure 1.** SAW sensors with non-uniform load.

In order to investigate the disturbance of complex distributed mass loading on the SAW propagation characteristics more accurately and improve the efficiency of simulation, we applied the 2-D COM theory to the simulation of a series of Rayleigh type SAW (R-SAW) sensors in this paper, and used the finite element method to solve the 2-D COM equations. Firstly, the structure model of SAW sensors with four patterns of the mass loading’s distribution were established by using the finite element simulation software (COMSOL Multiphysics); Next, the 2-D COM equation was introduced into the FEM model in the form of a generalized partial differential equation and solved. Finally, the displacement distributions of the main modes of the sensor under four load distribution patterns were drawn according to the solution results. At the same time, we calculated the insertion loss ($S_{21}$) parameters of the device, and obtained the sensors’ responses under four patterns of the load’s distribution.

To verify the accuracy of simulation results, we fabricated a series of SAW sensor chips with the loads in four distribution patterns, and measured their frequency responses. The experimental results confirm the advantage of using the 2-D COM equations to simulate the disturbance of complex distributed mass loading on SAW propagation characteristics.

### 2. Methods

#### 2.1. Two-Dimensional Coupling-of-Modes Equations

The 1-D COM theory was based on the plane-wave assumption that ignored the diffraction phenomenon in the propagation of the SAW. Thus, it can’t simulate the transverse mode of the device. In the 2-D COM theory, the surface acoustic wave is no longer approximated to a plane wave whose wave vector $\mathbf{K}$ is decomposed into two orthogonal components $\mathbf{K}_x$ and $\mathbf{K}_y$, corresponding to the longitudinal and transverse components of the device, respectively, as shown in Figure 2.

![Decomposition of the wave vector $\mathbf{K}$](image)

**Figure 2.** Decomposition of the wave vector $\mathbf{K}$.

According to the slowness curve of the SAW on piezoelectric substrate, the relationship between wave vector component $\mathbf{K}_x$ and $\mathbf{K}_y$ will be established approximately. The parabola approximate
form [14] was shown in Equation (1). And the biquadratic approximate form [6] was shown in Equation (2).

\[ k_x \approx k_0 - \frac{\gamma (k_y)^2}{2k_0} \]  

\[ k_x \approx k_0 + \frac{1}{2k_0}\gamma_1 k_y^2 + \frac{1}{24k_0^3}\gamma_2 k_y^4 \]  

Here, \( \gamma, \gamma_1, \gamma_2 \) are the parameters to characterize the anisotropy of piezoelectric substrate; \( k_0 \) is the wave number according to the electric period of the IDT.

Based on the 1-D COM equation and the slowness relation of the SAW, the 2-D COM equation can be obtained. As shown in Equation (3), the 2-D COM equations in the form of biquadratic approximation is adopted in this paper.

\[
\begin{align*}
\frac{\partial u_+}{\partial x} &= -jk_0 u_+ + j \frac{\gamma_1}{2k_0} \frac{\partial^2 u_+}{\partial y^2} + j \frac{\gamma_1}{24k_0^3} \frac{\partial^4 u_+}{\partial y^4} + j \kappa u_- + j aV \\
\frac{\partial u_-}{\partial x} &= jk_0 u_- - j \frac{\gamma_1}{2k_0} \frac{\partial^2 u_-}{\partial y^2} - j \frac{\gamma_2}{24k_0^3} \frac{\partial^4 u_-}{\partial y^4} - j \kappa^* u_+ - j a^* V \\
\frac{\partial^2 I}{\partial x \partial y} &= -2ja^* u_+ - 2ja u_- + jaC V
\end{align*}
\]  

Here, \( u_+, u_- \) are the particle displacements of waves propagating forward and backward directions, respectively; \( \kappa, a, C, V \) and \( I \) represent coupling coefficient, excitation coefficient, static capacitance, input voltage and output current.

### 2.2. Two-Dimensional Finite Element Model of the SAW Sensor Chip

In this paper, a two-port SAW resonator was selected as the sensing chip and its structure was shown in Figure 3a. The 2-D model of the SAW resonator was built in the finite element simulation software, as shown in Figure 3b. The structural parameters were given in Table 1.

![Figure 3](image-url)

**Figure 3.** (a) The structure of a two-port R-SAW resonator with three IDTs; (b) The 2-D model of the SAW resonator built in FEM software.
Table 1. The structural parameters of the 2-D FEM model.

| Structural Parameters                  | Value     |
|---------------------------------------|-----------|
| Period (\(\lambda\))                 | 6.074 (\(\mu\)m) |
| Aperture                              | 150*\(\lambda\) |
| Width of busbar                       | 10*\(\lambda\) |
| Length of Gaps between IDTs           | 1.25*\(\lambda\) |
| Length of Gaps between IDT and reflector | 1*\(\lambda\) |
| Number of fingers in IDT1             | 121       |
| Number of fingers in IDT2,3           | 61        |
| Number of fingers in reflector        | 401       |

To investigate the disturbance of complex distributed mass loading on the SAW propagation characteristics, four different load-distribution patterns were designed, as shown in Figure 4. The white parts were the mass loadings.

2.3. Two-Dimensional COM Parameters

The 2-D COM parameters are composed of the 1-D COM parameters \(v\), \(\kappa\), \(\alpha\), \(C\) and the anisotropic parameters \(\gamma_2\), \(\gamma_2\). The 1-D COM parameters can be determined by Equation (4).

\[
\begin{align*}
  v &= \frac{(f_{oc}+f_{oc})\lambda}{2} \\
  |\kappa| &= \frac{2n(f_{sc}-f_{sc})}{(f_{sc}+f_{sc})\lambda} \\
  |\alpha| &= \sqrt{\frac{V}{W_e}} \frac{f_{oc}+f_{oc}}{f_{sc}+f_{sc}} - 1 \\
  C &= \frac{2W_e}{V^2W}
\end{align*}
\]  

(4)

Here, \(f_{sc+}, f_{sc-}, f_{oc+},\) and \(f_{oc-}\) denote the up and down boundary frequency of the stop band in periodic shorted grating and open grating; \(V, W\) and \(W_e\) represent the input voltage, the acoustic aperture and the electrostatic energy.

To determine \(f_{sc+}, f_{sc-}, f_{oc+}, f_{oc-}\) and \(W_e\), a 3D periodic finite element model, including a pair of IDTs, was established as shown in Figure 5. And the substrate material and structural parameters of the model were given in Table 2.
By setting the boundary conditions of constant voltage or constant charge electrode, the periodic grating was controlled to be shorted grating and open grating. The resonant frequencies of symmetric and anti-symmetric Rayleigh surface acoustic wave (R-SAW) modes corresponding to the up and down boundary frequency of the stop band.

By performing static analysis in the FEM software (COMSOL Multiphysics), the electrostatic energy of the periodic element $W_e$ can be obtained.

The 1-D COM parameters of IDTs with and without mass loading were calculated by Equation (4), as shown in Table 3.

Table 3. 1-D COM parameters of IDTs with and without mass loading.

| 1-D COM Parameters | Non-Loaded | Loaded |
|---------------------|------------|--------|
| SAW velocity        | 3126 (m/s) | 3124 (m/s) |
| Normalized reflection coefficient | 0.040 | 0.044 |
| Normalized excitation coefficient | $2.49 \times 10^{-5}$ | $2.31 \times 10^{-5}$ |
| Static capacitance  | $4.00 \times 10^{-11}$ (F) | $4.48 \times 10^{-11}$ (F) |
By calculating the second and fourth derivatives at the zero point of the slowness curve, the anisotropic parameters were obtained [6].

\[
\gamma_1 = \left. \frac{d^2 (k_x/k_0)}{d(k_y/k_0)^2} \right|_{k_y=0}
\]

\[
\gamma_2 = \left. \frac{d^4 (k_x/k_0)}{d(k_y/k_0)^4} \right|_{k_y=0}
\]

To obtain the slowness curves of the SAW, the periodic conditions of the 3D periodic FEM model at the front and back side should be set up to a Floquet-Bloch boundary conditions form as follows:

\[
U_F = U_B \exp(jk_0 \tan(\theta) y)
\]

Here, \(U_F\) and \(U_B\) denote the wave amplitudes at front side and back side, and \(\theta\) is the oblique angle. By calculating the slowness of the SAW with different oblique angles, the slowness curves were obtained.

The slowness curves of the SAW in different domains on ST-X quartz substrate were shown in Figure 6.

![Figure 6. The slowness curves of the SAW in different domains.](image)

The anisotropic parameters \(\gamma_1\) and \(\gamma_2\) of each domain were obtained by Equations (5) and (6), as shown in Table 4.

| Domains            | \(\gamma_1\)  | \(\gamma_2\)  |
|--------------------|---------------|---------------|
| Grating            | -1.3754       | -0.3988       |
| Grating with SiO₂ load | -1.3499       | -0.6601       |
| Busbar             | -1.3366       | -0.1233       |
| Free space         | -1.3928       | 0.1871        |

2.4. Generalized PDE Form of 2-D COM Equations

In the PDE mode of FEM software (COMSOL Multiphysics), the 2-D COM equations in the form of biquadratic approximation were established into generalized PDE form [6].
The SAW displacements $U_+$ and $U_-$ in Equation (3) could be represented as Equation (8):

$$
U_+ = A_1 \exp(-j k_0 x) \\
U_- = A_2 \exp(j k_0 x)
$$

Then, the 2-D COM equations were rewritten as follows:

$$
\begin{align*}
\nabla \cdot \left[ A_1 \begin{pmatrix} 0 \\ -j \frac{\gamma_2}{2 k_0} \partial \frac{\partial A_1}{\partial y} \end{pmatrix} \right] &= -j \Delta A_1 - j \kappa A_2 + j \frac{\gamma_1}{2 k_0} A_3 + \alpha V \\
\nabla \cdot \left[ A_2 \begin{pmatrix} 0 \\ -j \frac{\gamma_2}{2 k_0} \partial \frac{\partial A_2}{\partial y} \end{pmatrix} \right] &= -j \Delta A_2 - j \kappa^* A_1 + j \frac{\gamma_1^*}{2 k_0} A_4 + \alpha^* V \\
\n\nabla \cdot \begin{pmatrix} 0 \\ \frac{\partial A_1}{\partial y} \end{pmatrix} &= A_3 \\
\n\nabla \cdot \begin{pmatrix} 0 \\ \frac{\partial A_2}{\partial y} \end{pmatrix} &= A_4 \\
\Delta &= \frac{\omega}{\beta} - k_0
\end{align*}
$$

Here, $\nabla$ was the divergence operator, $\Delta$ represented detuning coefficient.

In the reflector domains, the electric terms were equal to zero due to the electrical shorting of the gratings. In the gaps, PML (perfectly matched layer) and busbar domains, the electric terms and internal reflection terms were equal to zero because there were no internal reflections. What’s more, the PML domain was set to avoid reflections from the boundaries, thus a decay factor $\gamma_a(r)$ was introduced into the detuning coefficient of PML domain, as shown in Equation (10).

$$
\begin{pmatrix} \Delta_{PML} = \frac{\omega}{\beta} [1 - j \gamma_a(r)] - k_0 \\ \gamma_a(r) = \gamma_0 \frac{d}{r} \end{pmatrix}
$$

Here, $d$ represented the width of the PML domain, and $r$ was the distance from the boundary. The $\gamma_0$ in this paper was set up to 0.5 to achieve sufficient absorption effect.

2.5. Admittance Matrix and Insertion Loss

For the two-port SAW resonator, the relationship between the output current $I$ and the input voltage $V$ was given by Equation (11):

$$
\begin{pmatrix} I_1 \\ I_2 \end{pmatrix} = Y \begin{pmatrix} V_1 \\ V_2 \end{pmatrix} = \begin{pmatrix} Y_{11} & Y_{12} \\ Y_{21} & Y_{22} \end{pmatrix} \begin{pmatrix} V_1 \\ V_2 \end{pmatrix}
$$

Here, $Y$ matrix was the admittance matrix of the device.

The current of each port was obtained by Equation (12):

$$
I = \int \int_{\text{Domain}} -2 j \alpha u_+ - 2 j \alpha u_- + j \alpha CV
$$

By short-circuiting the IDTs of the two ports respectively and calculating the current of each port, the admittance matrix was obtained.

The principle of the short-circuiting operation to calculate the admittance matrix’s elements was summarized in Table 5.
Table 5. The principle of the short-circuiting operation to calculate the admittance matrix’s elements.

| Elements of Y Matrix | Short-Circuited IDTs |
|----------------------|----------------------|
| Y_{11}               | IDT1                 |
| Y_{12}               | IDT2, IDT3           |
| Y_{21}               | IDT1                 |
| Y_{22}               | IDT2, IDT3           |

In this paper, the insertion loss (S_{21}) parameter of SAW resonator was chosen as the response signal of the sensor. The relationship between the insertion loss (S_{21}) and the admittance matrix is given by Equation (13):

\[
S_{21} = \frac{-2Y_{21}\sqrt{Y_{01}Y_{02}}}{(Y_{01}+Y_{11})(Y_{02}+Y_{22})-Y_{12}Y_{21}}
\]

Insertion Loss = \[20\log_{10}|S_{21}| = 20\log_{10}\left|\frac{(Y_{01}+Y_{11})(Y_{02}+Y_{22})-Y_{12}Y_{21}}{2Y_{21}\sqrt{Y_{01}Y_{02}}}\right|\] (13)

where Y_{01}, Y_{02} denote transmission admittance.

2.6. Experimental Design

Using SiO_{2} as the loading material, we fabricated a series of SAW resonators with the loads in four distribution patterns. The fabrication process was as follows:

Firstly, metallic materials Al was deposited on the ST-X quartz substrate with a thickness of 2000 Å using an electron beam evaporator. Secondly, the photoresist (PR) was spin-coated, exposed and patterned for gratings. Thirdly, the Al was wet-etched and the PR was dissolved in acetone and the SAW resonators without SiO_{2} layers were fabricated. Finally, the SiO_{2} was deposited at 4 different distributions with a photomask we designed by using overlay technology, and the SAW resonators with the loads in four patterns were fabricated.

The photos of the SAW resonators under 4 different load patterns were taken by a microscope (LEICA DM4 M), as shown in Figure 7a–d. The information of material and structural parameters in the experiment was summarized in Table 6.

![Figure 7. Fabricated SAW resonators with SiO_{2} loads in distribution pattern 1~4. (a) Load pattern-1; (b) Load pattern-2; (c) Load pattern-3; (d) Load pattern-4.](image-url)
Table 6. The information of material and structural parameters in the experiment.

| Parameters            | Value         |
|-----------------------|---------------|
| Substrate material    | ST-X Quartz   |
| Load material         | SiO$_2$       |
| Grating material      | Al            |
| Thickness of gratings | 2000 (Å)      |
| Thickness of loads    | 1000 (Å)      |

In the experiment the input port (IDT 2, IDT 3) and output port (IDT1) were connected to the VNA (Agilent E5071B Network analyzer) by using a probe device, which was shown in Figure 8.

3. Results and Discussion

By solving the 2-D COM equations with FEM, we simulated the SAW sensors under four distributed patterns of mass loadings, respectively. Figure 9 showed the displacement distributions of the main modes under four load patterns.

By calculating the admittance matrix and the insertion loss (S21) parameters, we draw the frequency response curves of the device. As a comparison, we also obtained the frequency response curves using the 2-D SM [13], and the results were shown in Figure 10.

Of note was that the frequency response curves of load pattern 3–4 showed their center frequencies remained unchanged while the main peaks split. The reason for this phenomenon was that the SiO$_2$ layer disturbed the surface acoustic wave propagation characteristics on the pattern position. It was considered that the device was composed of several channels along the aperture direction, the disturbance from SiO$_2$ layer would lead to the change of the longitudinal resonance modes in those corresponding channels while it almost not has any impact on other channels [13]. The admittance of SAW device is approximately equal to the superposition of that in each channel. Therefore, the transverse distribution of the SiO$_2$ layer which only appeared in pattern 3–4 affected the shape of the frequency response curves.

Figure 9. The displacement distributions of the main modes: (a) without mass loading; (b–e) with four different load-distribution patterns.

Figure 10. The simulated frequency response curves of the SAW sensors under four different load-distribution patterns. (a) Load pattern-1; (b) Load pattern-2; (c) Load pattern-3; (d) Load pattern-4.

The experimental results were shown in Figure 11. Of note was that the machining errors led to the frequency excursion of the fabricated SAW resonators. To achieve a better comparison and exhibit the advantage of the method in this paper, the response curves of load pattern-4 from measurement, 2-D SM, and 2-D COM were carried out in Figure 12. Obviously, the results obtained by using the 2-D COM equations simulated the transverse modes of the devices effectively as well as the disturbance of
the mass loadings on the transverse modes (such as the parts circled in Figure 12a,c), which were more consistent with the experimental results.

![Figure 12. The comparison of results for load pattern-4 from measurement, 2-D SM, and 2-D COM with FEM: (a) the measured result; (b) the result of 2-D SM; (c) the result of 2-D COM with FEM.](image2)

4. Conclusions

With the wide application of SAW sensors in the field of biochemical detection, the distribution of the target analytes adhered to the sensor’s surface becomes more diverse. Therefore, it is very important to investigate the disturbance of complex distributed mass loading on the SAW propagation characteristics. Fortunately, in recent years, the finite element simulation technology has been greatly developed relying on computer technology, which provides greater help for researchers to carry out more accurate simulation work. In order to improve the accuracy of calculation and the efficiency of simulation modeling, we innovatively applied the 2-D COM theory to the simulation of SAW sensors, and used the finite element method to solve the partial differential equations. In this way, we simulated...
the transverse modes of SAW device and obtained the disturbance of the mass loadings on the transverse modes. The experimental results further confirmed the advantage of using the 2-D COM theory to simulate the disturbance of complex distributed mass loading on the SAW propagation characteristics.
