(Dated: September 3, 2021)

Two-dimensional systems with Rashba spin-orbit coupling are not Galilean invariant and therefore electron–electron collisions in them may affect the current. However when taken alone, they cannot ensure a nonzero dc resistivity, so their effects are masked by impurity scattering. Here we calculate the related finite-frequency response and show that the electron–electron scattering in clean Rashba conductors decreases the Drude weight while resulting in a finite dissipative component of the response outside of the Drude peak.

I. INTRODUCTION

Electron systems with spin-orbit coupling are not Galilean-invariant and therefore the electron–electron scattering may affect the electrical current in them. A considerable amount of recent theoretical work was related with their optical conductivity and finite-frequency absorption. Many papers dealt with single-particle absorption due to the transitions between spin-split subbands [1–7], which leads to a box-shaped contribution to the real part of optical conductivity at zero temperature. A negative correction to the Drude weight due to electron–electron interaction was obtained using the time-dependent Hartree-Fock approximation [8]. In Ref. [9], the finite-temperature absorption that results from excitation of electron–hole pairs was calculated by treating the electron–electron interaction as perturbation to the second order.

In this paper, we calculate the finite-frequency and finite-temperature electric response of two-dimensional (2D) Rashba electron gas with electron–electron scattering beyond the perturbation theory. To this end, we use the Boltzmann equation similar to that derived recently [10] for calculating the dc conductivity of these systems. Despite the lack of Galilean invariance, the Rashba electron gas is translationally invariant and therefore there is a perturbation of electron distribution of a definite form that is stable with respect to electron–electron collisions. For this reason, a finite dc conductivity may be ensured only in the presence of an additional mechanism of scattering like impurities that suppress this perturbation. But in the case of an ac response, the time derivative in the Boltzmann equation plays the same role as the additional scattering and eliminates the divergence of the current. We restrict ourselves to the frequencies much lower than those related with intersubband transitions.

The paper is organized as follows. Section II presents general equations. In Section III, the existence of the perturbation of electron distribution immune to the electron–electron scattering is proved for an arbitrary dispersion law. Section IV presents the calculations and results, and finally, Section V contains their discussion. The Appendix presents some lengthy expressions.

II. THE MODEL

As a model, we consider a 2D electron gas with Rashba spin-orbit coupling (SOC), which resides in the xy plane and is described by the Hamiltonian

$$\hat{H} = \frac{\hat{p}_x^2 + \hat{p}_y^2}{2m} + \alpha (\hat{\sigma}_x \hat{p}_y - \hat{\sigma}_y \hat{p}_x),$$  (1)

where \(\alpha\) is the Rashba coupling constant and \(\hat{\sigma}_{x,y}\) are the Pauli matrices. The diagonalization of this Hamiltonian results in two subbands with dispersion laws

$$\varepsilon_\nu(p) = \frac{p_x^2 + p_y^2}{2m} + \nu \alpha \sqrt{p_x^2 + p_y^2}, \quad \nu = \pm 1,$$  (2)

which correspond to the two opposite helicities of electrons (see Fig. 1). These subbands are tangent at \(p_x = p_y = 0\), and the Fermi surface is doubly connected below and above \(E_F = 0\). The minimum of the lower subband is given by \(-E_{SO}\), where \(E_{SO} = m\alpha^2/2\). The eigenstates of the Hamiltonian Eq. (1) are two-component
spinors with components in the \( \hat{s}_z \) basis
\[
\psi_{\nu}(r) = \frac{1}{\sqrt{2}} \ e^{i p r / \hbar} \left( e^{i \chi_p / 2} \right),
\] (3)
where \( \chi_p = \arctan(p_x / p_y) \), so the spin is directed perpendicularly to \( p \) either clockwise or counterclockwise. We assume that the electron–electron interaction is weak and does not affect the electron spectrum.

III. BOLTZMANN EQUATION AND COLLISION INTEGRAL

The most simple and convenient way to calculate the response of weakly interacting electron system to a slowly varying electric field as compared with the subband separation is the Boltzmann equation
\[
\frac{\partial f_{\nu}}{\partial t} + e E(t) \frac{\partial f_{\nu}}{\partial p} = I_{\nu} = \sum_{\nu'} \sum_{p_1} \sum_{p_2} \int \frac{d^2 p_1}{(2\pi \hbar)^2} \int \frac{d^2 p_2}{(2\pi \hbar)^2} \int d^2 p_3 \times \left( \delta (p + p_1 - p_2 - p_3) \delta (\epsilon_{\nu} + \epsilon_{\nu_1} - \epsilon_{\nu_2} - \epsilon_{\nu_3}) \times W(\nu p, \nu_1 p_1; \nu_2 p_2, \nu_3 p_3) \times \left[ (1 - f)(1 - f_1) f_2 f_3 - f f_1 (1 - f_2)(1 - f_3) \right] \right),
\] (5)

where \( f_\nu(p,t) \) is the electron distribution in the basis of exact eigenstates of the Hamiltonian \[13\]. The electron–electron collision integral may be written in the form
\[
I_{\nu} = \sum_{\nu'} \sum_{p_1} \sum_{p_2} \sum_{p_3} \int \frac{d^2 p_1}{(2\pi \hbar)^2} \int \frac{d^2 p_2}{(2\pi \hbar)^2} \int d^2 p_3 \times \delta (p + p_1 - p_2 - p_3) \delta (\epsilon_{\nu} + \epsilon_{\nu_1} - \epsilon_{\nu_2} - \epsilon_{\nu_3}) \times W(\nu p, \nu_1 p_1; \nu_2 p_2, \nu_3 p_3) \times \left[ (1 - f)(1 - f_1) f_2 f_3 - f f_1 (1 - f_2)(1 - f_3) \right] \times \left( \frac{\partial f_\nu}{\partial t} + e E(t) \frac{\partial f_\nu}{\partial p} \right)
\]
(4)

This equality may not hold if the system lacks either time-reversal or inversion symmetry, but its violations show up only beyond the Born approximation \[10\].

Regardless of the number of subbands and the explicit form of \( \epsilon_{\nu}(p) \), the collision integral Eq. \[5\] is always turned into zero by a distribution of the form \[13\]
\[
f_\nu(p) = f(\epsilon_\nu + u p),
\] (6)
where \( u \) is an arbitrary constant vector and \( f(\epsilon) \) is the Fermi distribution function. With this substitution, one easily obtains that
\[
(1 - f)(1 - f_1) f_2 f_3 = f f_1 f_2 f_3 \times \exp \left( \frac{\epsilon_{\nu}(p) + \epsilon_{\nu_1}(p_1) + u (p + p_1)}{T} \right)
\] (7)
and a similar equality for \( f f_1 (1 - f_2)(1 - f_3) \). Therefore the difference in the square brackets in Eq. \[5\] turns into zero because of the momentum and energy conservation. As a consequence, any perturbation of the form
\[
\delta f_{\nu}(p) = u p \ f(\epsilon_\nu) \ [1 - f(\epsilon_\nu)]
\] (8)
turns the collision integral into zero to the first approximation. This is the reason why the electron–electron scattering alone cannot ensure a finite dc conductivity even for multiband electron systems \[10\].

IV. ELECTRICAL RESPONSE

We assume that the electron–electron interaction in the conductor is screened by a nearby metallic gate such that the distance to the gate \( d_0 \) is smaller than the Fermi wavelength, so that the interaction potential may be presented in the form \( V(\mathbf{r} - \mathbf{r}') = 4\pi e^2 d_0 k^{-1} \delta(\mathbf{r} - \mathbf{r}') \), where \( e \) is the electron charge and \( k \) is the dielectric constant. Therefore the scattering probability \( W \) in Eq. \[5\] may be calculated in the Born approximation and equals
\[
W(\nu p, \nu_1 p_1; \nu_2 p_2, \nu_3 p_3) = \frac{8\pi^3}{3} \frac{e^4 d_0^2}{\hbar^2} \ [1 - \nu_1 \cos(p_1, p_1)] \times [1 - \nu_2 \nu_3 \cos(p_2, p_3)].
\] (9)

As the system is rotationally symmetric in the \( xy \) plane, the linear response to the electric field \( E(t) \) may be conveniently shown in the form
\[
f_\mu(\varepsilon, \varphi) = \tilde{f}(\varepsilon) + C_\mu(\varepsilon) f(\varepsilon) \left[ 1 - \tilde{f}(\varepsilon) \right] \cos \varphi,
\] (10)
where \( \mu = \pm 1 \) labels the Fermi contours with larger momentum \( p_1 \) and smaller momentum \( p_{-1} \) for a given \( E_F \), the energy \( \varepsilon \) is measured from \( E_F \), and \( \varphi \) is the angle between \( E \) and \( p \). Note that the corresponding velocities \( v_\mu = (\partial p_\mu / \partial \varepsilon)^{-1} \) for the same \( \varepsilon \) are equal at \( E_F > 0 \) but have opposite signs at \( E_F < 0 \), so that \( v_{-1} = v_1 \text{ sgn} E_F \). Assuming that \( p_\mu \) and \( v_\mu \) are independent of energy near the Fermi level and that the coefficients \( C_\mu \) are even functions of \( \varepsilon \), one may bring the linearized collision integral Eq. \[5\] to the form \[10\]
\[
I_{\mu}^{\text{ee}}(\varepsilon, \varphi) = \frac{2 \Gamma_{\text{ee}} \cos \varphi}{T^2} \int d\varepsilon' K(\varepsilon, \varepsilon') \left\{ \ln \frac{E_F}{T} \Phi_\mu[C_\mu(\varepsilon')] - C_\mu(\varepsilon) + \Psi_\mu \left[ \frac{p_{-1} C_{-\mu}(\varepsilon') - p_{-\mu} C_\mu(\varepsilon')}{{p_{-1} + p_{-\mu}}} \right] \right\},
\] (11)
where \( \Gamma_{\text{ee}}(T) = 16\pi^2 e^4 d_0^2 T^2 (p_1 + p_{-1})/32\pi^3 h^5 k^2 v_1^3 \) is the effective rate of electron–electron collisions,
\[
K(\varepsilon, \varepsilon') = \left[ 1 - \tilde{f}(\varepsilon) \right] \frac{\varepsilon - \varepsilon'}{\varepsilon(\varepsilon - \varepsilon')/T - 1} \tilde{f}(\varepsilon'),
\] (12)
and the explicit expressions for the dimensionless functions \( \Psi_\mu(E_F/E_{SO}) \) are given in the Appendix. It is clearly seen that \( I_{\mu}^{\text{ee}}(\varepsilon, \varphi) \) is turned into zero by the distribution of the form Eq. \[6\], i. e. with \( p_{-1} C_{-1} = p_{-1} C_1 = \text{const}(\varepsilon) \). The logarithmic singularity in the first term in curly brackets in Eq. \[12\] is a characteristic feature of 2D scattering that results from head-on and small-angle
collisions and manifests itself in the inverse quasiparticle lifetime [14] and thermal conductivity [16] for 2D conductors with singly connected Fermi surface.

Assume that the electric field has a sinusoidal time dependence \( E(t) = e^{-i(\omega + i\delta)t} E_\omega \), where \( \delta \) is infinitely small and positive. With the substitution Eq. \( (11) \), the Boltzmann equation Eq. \( (4) \) results in a system of two integral equations in \( C_\mu(\xi) \). This system may be solved by the method first proposed by Brooker and Sykes [17]. To this end, we introduce a new variable

\[
\rho_\mu(\varepsilon) = [\hat{f} (1 - \hat{f})]^{1/2} C_\mu(\xi),
\]

which makes the kernel of the integral in Eq. \( (12) \) a function of the difference \( \varepsilon' - \varepsilon \). Therefore the system of integral equations may be brought to the differential form by a Fourier transform

\[
\hat{\rho}_\mu(u) = \int d\xi e^{-i\xi u} \rho_\mu(\varepsilon),
\]

A subsequent introduction of the new independent variable \( \xi = \tanh(\pi T u) \) brings Eqs. \( (4) \) to the form

\[
\Gamma_{\text{ee}} \left[ \ln \frac{E_F}{T} \Phi_\mu (\hat{L} + 2) \hat{\rho}_\mu - 2 \Psi_\mu \frac{p_{\mu} \hat{\rho}_\mu - p_{\mu} \hat{\rho}_{-\mu}}{p_{1} + p_{-1}} \right] + \frac{1}{\pi^2} \frac{i\omega}{1 - \xi^2} \hat{\rho}_\mu = - \frac{1}{\pi} eE v_\mu \frac{1}{1 - \xi^2},
\]

where \( \hat{L} \) is the differential operator

\[
\hat{L} \phi = \frac{\partial}{\partial \xi} \left[ (1 - \xi^2) \frac{\partial \phi}{\partial \xi} \right] - \frac{\phi}{1 - \xi^2}.
\]

The solutions of Eqs. \( (17) \) may be presented in the form of a series

\[
\hat{\rho}_\mu(\xi) = \sum_{m=0}^{\infty} \gamma_{\mu m} \phi_{2m}(\xi),
\]

where \( \phi_m(\xi) \) are the eigenfunctions of operator \( \hat{L} \) with corresponding eigenvalues \( -(m+1)(m+2) \) [18]. A substitution of the expansions Eqs. \( (19) \) into Eqs. \( (17) \) results in an infinite system of equations for the coefficients \( \gamma_{\mu m} \) of the form

\[
2 \Gamma_{\text{ee}} \left[ m (2m + 3) \ln \frac{E_F}{T} \Phi_\mu \gamma_{\mu m} \right. \\
+ \left. \Psi_\mu \frac{p_{\mu} \gamma_{\mu m} - p_{\mu} \gamma_{-\mu m}}{p_1 + p_{-1}} \right] + \frac{i\omega}{\pi} \sum_{m=0}^{\infty} Y_{mn} \gamma_{mn} = eE v_\mu X_m / \pi,
\]

where \( Y_{mn} \) are the matrix elements of \( (1 - \xi^2)^{-1} \) between \( \phi_{2m} \) and \( \phi_{2n} \), and \( X_m \) are the projections of \( (1 - \xi^2)^{-1/2} \) on \( \phi_{2m} \). The explicit expressions for these quantities are given in the Appendix. The current density is given by the sum [10]

\[
j = \frac{e}{8\pi^2 \hbar^2} \sum_{\mu} p_\mu \text{sgn} v_\mu \sum_m X_m \gamma_{\mu m}.
\]

In the high-frequency limit, one easily obtains directly from Eq. \( (4) \) that \( C_\mu = eE v_\mu / \omega T \) and therefore the imaginary part of the response is

\[
\sigma''_\mu = \frac{e^2}{4\pi \hbar^2 \omega} v_1 (p_1 + p_{-1}),
\]

while the dissipative part \( \sigma' \) is zero. Equation \( (22) \) coincides with the results of [7]. In the opposite limit \( \Gamma_{\text{ee}} \gg \omega \), one cannot simply set \( \omega = 0 \) because of the existence of the perturbation [9] with zero relaxation rate, which leads to the divergence of \( \gamma_{\mu 0} \). This divergence can be eliminated by keeping \( \omega \) small but finite and isolating the most singular in \( \omega \) contribution to \( \sigma \). This contribution may be obtained by setting \( \gamma_{\mu m} = 0 \) for all \( m \neq 0 \) and solving the resulting systems of two equations for \( \gamma_{\mu 0} \). The resulting conductivity is

\[
\sigma_{ee} = i \frac{e^2}{4\pi \hbar^2 \omega} v_1 \frac{1}{\omega + i\delta} \left( \frac{\mp + \text{sgn} E_F \mp_{-1}}{(\Psi_{-1} + \text{sgn} E_F \Psi_1)} \right),
\]

At \( \omega \neq 0 \), it is purely imaginary and inversely proportional to \( \omega \), like \( \sigma''_0 \). Though it is temperature-independent, it still depends on the properties of electron–electron scattering through the quantities \( \Psi_{\pm 1} \).

In the leading approximation, the real part of conductivity is proportional to \( \delta(\omega) \). The dissipative part of conductivity at \( \omega \neq 0 \) is given by the subleading term, which is independent of \( \omega \). To calculate it, one should, in principle, take into account the components of Eq. \( (19) \) with higher \( m \). The most singular parts of \( \gamma_{\mu 0} \) should be substituted into Eqs. \( (20) \) with \( m \neq 0 \), and the solutions should be substituted back into Eqs. \( (20) \) with \( m = 0 \). However because of the condition \( \ln(E_F/T) \gg 1 \), the contribution from \( \gamma_{\mu m} \) with \( m > 0 \) is small, and it is sufficient to find the subleading term in the equations with \( m = 0 \). Therefore at \( \omega \neq 0 \),

\[
\sigma'_{ee} = \frac{3 \frac{e^2}{16\pi^3 \hbar^2} v_1 (p_1 + p_{-1})}{\Gamma_{\text{ee}}} \times \frac{(\Psi_{-1} - \text{sgn} E_F p_{-1} - \text{sgn} E_F \Psi_1 p_1)}{(\Psi_{-1} p_1 + \Psi_1 p_{-1})^2}.
\]

It is noteworthy that neither \( \sigma'_{ee} \) nor \( \sigma''_{ee} \) contains the \( \ln^{-1}(E_F/T) \) factor, much like the dc conductivity in a presence of weak impurity scattering [10]. At \( E_{SO} \ll E_F \), the scattering corrections to the conductivity are proportional to \( E_{SO}^{3/2} \), so that

\[
\sigma'_{ee} \approx \frac{3 e^2 E_{SO}^{3/2}}{64\pi^3 \hbar^2 \Gamma_{ee} E_F^{1/2}}, \quad \sigma''_{ee} = \sigma''_0 \approx -\frac{e^2 E_{SO}^{3/2}}{\pi \hbar^2 \omega E_F^{1/2}}.
\]

V. DISCUSSION

The dependence of the imaginary and real parts of conductivity on the Fermi energy at \( \omega \ll E_{SO} \) is shown in
FIG. 2. The dependence of the imaginary part of conductivity $\sigma''$ times $\omega$ on $E_F$ in the zero-temperature limit (blue curve) and in the high-temperature limit (red curve).

FIG. 3. The dependence of the real part of conductivity $\sigma'$ on $E_F$ at $\omega \neq 0$. The solid red line shows $\sigma'_{ee}$ in the limit $\Gamma_{ee} \gg \omega$ in arbitrary units. For comparison, the dashed blue line shows a sketch of $\sigma'$ in the limit of strong impurity scattering.

FIG. 4. A log-log plot of $\sigma'$ in arbitrary units vs $\omega/\Gamma_{ee}$ for $E_F/E_{SO} = -0.85$ and $\Gamma_{imp} = 10^{-4}\Gamma_{ee}$.

electron scattering does not affect the conductivity. It is noteworthy that unlike $\sigma''_0$, $\sigma''_{ee}$ exhibits no kink and $d\sigma''_{ee}/dE_F$ is continuous at this point.

In contrast to the imaginary part, the dissipative part $\sigma''_{ee}$ scales as $T^{-2}$ even at $\Gamma_{ee} \gg \omega$. Another clear distinction from $\sigma''_0$ is the nonmonotone $\sigma''_{ee}(E_F)$ dependence with $\sigma''_{ee}(0) = 0$. The disappearance of dissipation at $E_F = 0$ is quite natural because the inner Fermi contour shrinks into a point at this Fermi energy and the Fermi surface becomes effectively singly connected. Our results for $\sigma'$ sharply differ from the $T^2/\omega^2$ dependence obtained in [9] in the low-frequency limit using second-order perturbation theory in $V_0$. The suppression of $\sigma''$ is a consequence of the emergence of a finite dissipation, in agreement with the Kramers–Kronig relations. Unlike the suppression predicted by Agarwal et al. [8], it is temperature-dependent and takes place even at weak electron–electron interaction.

Suppose now that the material is not perfectly clean. An important question is how the dissipative conductivity $\sigma''_{ee} \propto \Gamma_{ee}^{-1}$ given by Eq. (24) is related with the dc conductivity found to be inversely proportional to the impurity scattering rate $\Gamma_{imp}$ in Ref. [10]. The answer is given by Fig. 4 which shows the frequency dependence of $\sigma'$ in a presence of the electron–electron and much weaker impurity scattering. This dependence exhibits two clearly seen plateaus at $\omega \leq \Gamma_{imp}$ and at $\omega \gg \Gamma_{imp}$. The former plateau presents the results of [10], while the latter corresponds to Eq. (24). In other words, the results of [10] correspond to the limit $\omega \ll \Gamma_{imp}$, while Eq. (24) corresponds to $\omega \gg \Gamma_{imp}$. Naturally, the presence of impurities eliminates the $\delta(\omega)$ peak.

The finite-frequency dissipation may be more convenient for experimental investigations of electron–electron scattering than the dc conductivity because it does not depend on the type of impurities in the conductor [19].
Though this dissipation is nonzero both above and below the band-crossing point \( E_F = 0 \), it may be more conveniently observed below this point. One of the conditions is \( \omega < \Gamma_{ee} \). For example, for InAs, which exhibits Rashba parameter \( \hbar \alpha = 1.2 \text{eVÅ} \), the electron concentration \( 10^{10} \text{cm}^{-2} \), the 2D gas–gate distance of 100 nm, and \( T = 4 \text{K} \), the frequency has to be smaller than \( \Gamma_{ee} \approx 0.5 \text{THz} \). On the other hand, these experiments would require high-quality samples because the electron–impurity scattering length has to be much larger than \( l_{ee} \sim 40 \text{nm} \).

The above calculations were performed for point-like electron–electron interactions because this model allows an analytical solution. However the existence of zero-relaxation modes, which is their cornerstone, stems from very general properties of the system like translational invariance and Fermi statistics, so the suppression of Drude weight and finite dissipation are not the consequences of point-like interaction and should be also observed for a long-range potential.

ACKNOWLEDGMENTS

This work was carried out within the framework of the state task.

Appendix: Explicit expressions for some quantities

The quantities \( \Phi_\mu \) and \( \Psi_\mu \) in the collision integral Eq. \([12]\) are defined by the expressions

\[
\frac{E_F}{T} \Phi_\mu = \sum_{\mu_1} \sum_{\mu_2} \sum_{\mu_3} \frac{p_{\mu_1}}{p_\mu + p_{-\mu}} \int_0^\pi d\chi (1 - \mu_1 \cos \chi) \\
\quad \times \Theta (\mathcal{D}_\mu_{\mu_3}) \mathcal{D}^\mu_{\mu_2\mu_3} / 2, \tag{A.1}
\]

and

\[
\Psi_\mu = \sum_{\mu_1} \sum_{\mu_2} \sum_{\mu_3} \frac{p_{\mu_1}}{p_\mu + p_{-\mu}} \int_0^\pi d\chi (1 - \mu_1 \cos \chi) \Theta (\mathcal{D}_\mu_{\mu_3}) \\
\quad \times \mathcal{D}^{\mu_2\mu_3} / 2 (1 - \delta_{\mu_1 \mu_3} \cos \chi - 2 \delta_{\mu_2 \mu_3} \lambda_{\mu_3} \mu_{\mu_3}), \tag{A.2}
\]

where \( \mu_{\mu_3} \) stands for \( \mu_1 \mu_2 \mu_3 \).

\[
\mathcal{D}_{\mu_{\mu_3}} = \frac{(p_2 + p_3)^2 - p^2 - p_1^2 - 2 p p_1 \cos \chi}{p^2 + p_1^2 + 2 p p_1 \cos \chi - (p_2 - p_3)^2}, \tag{A.3}
\]

and

\[
\lambda_{\mu_{\mu_3}} = \frac{1}{2} \frac{p_2^2 - p_3^2 + p^2 + p_1^2 + 2 p_1 \cos \chi}{p^2 + p_1^2 + 2 p_1 \cos \chi} \times (p + p_1 \cos \chi) / p_2. \tag{A.4}
\]

The normalized eigenfunctions of differential operator \( \hat{L} \) Eq. \((18)\) are given by the expressions

\[
\phi_m (\xi) = \sqrt{\frac{(2 m + 3)(m + 2)}{8 (m + 1)}} \sqrt{1 - \xi^2} P_m^{(1,1)} (\xi), \tag{A.5}
\]

where \( P_m^{(1,1)} (\xi) \) are Jacobi polynomials. The coefficients of expansion of \((1 - \xi^2)^{-1/2}\) in these functions are given by

\[
X_m = \int_{-1}^1 d\xi \frac{\phi_{2m} (\xi)}{\sqrt{1 - \xi^2}} = \sqrt{\frac{4 m + 3}{(2 m + 1)(m + 1)}}. \tag{A.6}
\]

The matrix elements of \(1/(1 - \xi^2)\) between the eigenfunctions of \( \hat{L} \) are given by the equation

\[
Y_{mn} = \int_{-1}^1 d\xi \frac{\phi_{2m} (\xi) \phi_{2n} (\xi)}{1 - \xi^2} = \min (m, n) + 1/2 \max (m, n) + 1 \\
\quad \times \sqrt{(4 m + 3)(m + 1)(4 n + 3)(n + 1)} \bigg/ (2 m + 1)(2 n + 1). \tag{A.7}
