Abstract: In this paper, we present a nonlinear coordinated excitation and static var compensator (SVC) control for regulating the output voltage and improving the transient stability of a synchronous generator infinite bus (SGIB) power system. In the first stage, advanced nonlinear methods are applied to regulate the SVC susceptance in a manner that can potentially improve the overall transient performance and stability. However, as distant from the generator measurements are needed, time delays are expected in the control loop. This fact substantially complicates the whole design. Therefore, a novel design is proposed that uses backstepping methodologies and feedback linearization techniques suitably modified to take into account the delayed measurement feedback laws in order to implement both the excitation voltage and the SVC compensator input. A detailed and rigorous Lyapunov stability analysis reveals that if the time delays do not exceed some specific limits, then all closed-loop signals remain bounded and the frequency deviations are effectively regulated to approach zero. Applying this control scheme, output voltage changes occur after the large power angle deviations have been eliminated. The scheme is thus completed, in a second stage, by a soft-switching mechanism employed on a classical proportional integral (PI) PI voltage controller acting on the excitation loop when the frequency deviations tend to zero in order to smoothly recover the output voltage level at its nominal value. Detailed simulation studies verify the effectiveness of the proposed design approach.

Keywords: power system control; transient stability; nonlinear analysis; static var compensators; SGIB power systems

1. Introduction

Power systems are nonlinear, large-scale, widely dispersed systems with many different interconnected components. Typically, power systems controls are structured in several hierarchical levels (primary, secondary, tertiary). The primary level control of power systems plays a central role in maintaining transient stability and obtaining a desired system performance. Generator excitation control is employed at the primary level in order to improve the power system stability, especially after short-circuit faults or other major disturbances. This is achieved with the use of supplementary excitation control devices called power systems stabilizers (PSSs). Conventional PSS are designed using linear control approaches and are combined with the automatic voltage regulator (AVR) part to result in a common form, known as an AVR/PSS controller. In the case of a synchronous generator infinite bus (SGIB) power system, linear excitation controllers have been proposed in [1], which are based on linearizations around the operating point. Nonlinear control theory, on the other hand,
seems to provide a more reliable and robust tool for the analysis and design of power systems [2]. Under this view, several nonlinear excitation control methods have been proposed including feedback linearization [3,4], adaptive control [4–7], and robust designs [8,9].

Beyond the traditional control of power systems through the excitation circuits of the rotating generators, static power-electronic devices are proposed to be installed in the power transmission system to support their transient behavior. Such static power-electronic components are the flexible alternating current transmission system (FACTS) devices that are suitably controlled to increase the power transfer capability and network stability [10,11]. Static var compensators (SVCs) are FACTS devices that correct the power factor and the grid voltage at the point of connection [12–14]. In this paper, we consider a widely used thyristor controlled reactor-fixed capacitor (TCR-FC) SVC [15,16]. Voltage is regulated at the SVC bus as follows: If voltage amplitude is needed to decrease (i.e., in case of capacitive load conditions), the SVC uses TCRs to absorb vars from the system. If voltage amplitude is needed to increase (in case of inductive load conditions), the capacitor banks are automatically switched-in to inject vars to the system. In several studies [12–19], coordinated excitation and SVC control has been considered for transient stability enhancement and voltage regulation.

Recent advances in wide-area measurement systems (WAMS) technology have initiated the use of phasor measurement unit (PMU) devices for controlling power systems. Communication time-delays are inevitably introduced during the transmission of wide-area signals. The effect of these delays on the overall power system stability has attracted significant research interest [20,21] because they constitute additionally negative factors in designing an effective control.

In this paper, we consider a single machine infinite bus power system with a TCR-FC SVC connected in the tie-lines between the generator and the infinite bus. The synchronous generator is represented by its third-order nonlinear model and the SVC dynamics from its first-order model. A feedback linearization approach is used, resulting in a linear dynamic system representation with two controlled inputs, the generator excitation input and the input of the SVC regulator. Both inputs are used in conjunction to formulate a faster and effective feedback loop that can substantially improve the overall system transient response and stability. Applying backstepping-based techniques and using distant measurements from the generator side, an excitation and a nonlinear SVC controller are designed. As the time delays in the measurements are essential for the whole design, a detailed nonlinear theoretical analysis is conducted that considers this influence and, as shown in the paper, proves that as long as the time delays are sufficiently small, then all closed-loop signals are bounded and the power angle deviations exponentially converge to zero. The design is completed by a coordinated frequency and voltage controller that utilizes a soft switching mechanism for both the excitation input and the SVC compensator, which extends the fuzzy switching coordination approach of [22]. The excitation input initially employs the proposed nonlinear control, while in the sequel, after the large frequency deviations are mitigated, it switches in a smooth way to a classical automatic voltage regulator and power system stabilizer (AVR/PSS). It is apparent that also in the case when the delays are not sufficiently small, then a classical proportional integral (PI) voltage controller is used. The simulation results indicate that the proposed approach yields better results than the simple AVR/PSS and PI SVC control.

The main contributions and novelties of this work with respect to the related literature [13–19,22] are summarized as follows:

- This work is the first to consider the use of SVC control laws with delayed measurements from the generator in order to improve the overall transient stability and performance. The proposed approach makes necessary a new theoretical analysis that takes into account the effect of time-delays.
- The soft switching coordination approach of [22], which improves global transient stability and voltage regulation, is extended to the SVC control case. New membership functions are considered based on suitably defined fuzzy rules that consider not only the frequency variations, but also the magnitude of the time delays.
The rest of the paper is organized as follows. In Section 2, the mathematic model of the system is outlined and the problem is formulated. The backstepping/feedback linearization method is used in Section 3 to design the excitation and SVC controllers. In Section 4, a detailed stability analysis for the closed-loop system is carried out. The coordinated frequency and voltage control is proposed in Section 5. Simulation results are given in Section 6. Finally, in Section 7, some concluding remarks are given.

2. Mathematical Model and Problem Formulation

A simplified model for a generator and an SVC system, which forms a three-bus system shown in Figure 1, is considered. The SVC is connected to a bus located at an intermediate point of the transmission line.

The classical third-order single-axis dynamic generator model [23] is used for the design of the excitation controller, which neglects dynamics with very short time constants, and is given by the following equations:

\[ \dot{\delta}(t) = \omega(t) - \omega_0 \]  
\[ \dot{\omega}(t) = \frac{-D}{M}(\omega(t) - \omega_0) + \frac{\omega_0}{M}(P_m - P_e(t)) \] 
\[ E'_q(t) = \frac{1}{T_d}(E_f(t) - E_q(t)) \] 

where

\[ E_q(t) = E'_q(t) + (x_d - x'_d)I_d(t) \] 
\[ E_f(t) = k_c u_f(t) \]

In this model, the sub-transient and damper windings effects are neglected. Moreover, the flow terms \( \lambda_d \) and \( \lambda_q \) in the stator voltage equations are omitted as they are considered negligible compared with the speed voltage terms.

We consider a widely used TCR-FC SVC (see Figure 1), which consists of a fixed capacitor in shunt with a thyristor-controlled inductor. Let \( B_C \) be the susceptance of the capacitor in SVC and \( B_L(t) \) be the susceptance of the inductor in SVC. Let it be that \( B_L(t) \) is regulated by the firing angle of the thyristor. Then, the equivalent dynamic model of SVC can be written as [15–17]

\[ B_L(t) = \frac{1}{T_B(t)}(-B_L(t) + B_{L0} + k_B u_B(t)) \] 

where \( B_{L0} \) is the initial susceptance of the TCR, \( T_B \) is the time constant of the SVC regulator, \( k_B \) the gain, and \( u_B \) the input of the SVC regulator.

The coordinated control design for the generator and the static VAR compensator must take into account the SVC controller effect on the generator dynamics. From the network topology depicted in Figure 1, the active electrical power is given by

\[ P_e = \frac{E'_q \sin \delta}{X} \]

where \( X \) is the total reactance value.
To examine the transient system response, a symmetrical three-phase short-circuit fault in the tie-line connecting the generator and the static VAR compensator is considered, as shown in Figure 1. During the three-phase short-circuit fault, the total reactance value $X$ changes. An analysis of the equivalent circuits pre-fault, during fault, and post-fault yields the respective values of $X$. These network configurations are shown in Figures 2–4, whereas the detailed calculations are given in Appendix A.

**Figure 1.** Simplified generator and static var compensator (SVC) three-bus model. AVR/PSS, automatic voltage regulator and power system stabilizer; TCR, thyristor controlled reactor; FC, fixed capacitor.

we have that

\[ a \text{ variable be } z, \]  

\[ \text{Energies 2020} \]

3. Control Design Based on Backstepping and Feedback Linearization Techniques

The control objective is to design the excitation input \( E_f \) and the SVC controller \( u_B \) such that the angle deviations \( \Delta \delta \) converge exponentially fast to zero. To that end, we adopt a backstepping approach in the control design for the transient stability enhancement similar to [3]. Let the first error variable be \( z_1 = \Delta \delta \) with dynamics \( \dot{z}_1 = \Delta \omega \). If we define the first virtual control law \( \alpha_1 = -c_1 \Delta \delta \) with \( c_1 > 0 \), then for the new error variable, \( z_2 = \Delta \omega - \alpha_1 \), and the nonnegative function, \( V_1 = (1/2)z_1^2 \), we have that \( \dot{V}_1 = -c_1 z_1^2 + z_1 z_2 \). The dynamics of \( z_2 \) are given by

\[ \dot{z}_2(t) = \left(c_1 - \frac{D}{M}\right)\Delta \omega(t) - \frac{a_0}{M} \Delta P_e \]  

If we select the second virtual control law as

\[ \alpha_2 = \frac{M}{a_0} \left(c_1 - \frac{D}{M}\right)\Delta \omega + z_1 + c_2 z_2 \]
with the third error variable \( z_3 = \Delta P_e - \alpha_2 \), then the dynamics of \( z_2 \) are \( \dot{z}_2 = -z_1 - c_2 z_2 - (\omega_0/M) z_3 \).

The overall error variable transformation is

\[
\begin{bmatrix}
  z_1 \\
  z_2 \\
  z_3 
\end{bmatrix} = \begin{bmatrix}
  1 & 0 & 0 \\
  c_1 & 1 & 0 \\
  -\frac{M}{\omega_0} (1 + c_1 c_2) & -\frac{M}{\omega_0} (1 + c_2 - \frac{D}{M}) & 1
\end{bmatrix} \begin{bmatrix}
  \Delta \theta \\
  \Delta \omega \\
  \Delta P_e 
\end{bmatrix}
\]  

(16)

Then, the dynamics of the \( z_3 \) error variable are described by

\[
\dot{z}_3 = \frac{E_f \cos \delta}{X} \Delta \omega + \frac{1}{T_{\omega_0}} (E_f - E_f') (x_d - x_d') \frac{\sin \delta}{X} - \frac{a P_e (B_L(t) + B_B + k_m u_B(t))}{E(t) X (y_1 y_2 (B_L(t) - B_C) + 1)} \\
+ \frac{M}{\omega_0} (1 + c_1 c_2) (c_2 - \frac{D}{M}) \Delta \omega - \frac{M}{\omega_0} (1 + c_1 c_2) \Delta P_e
\]  

(17)

where expressions (11) to (13) are taken into account.

We then select a nonlinear feedback linearizing excitation control law of the following form:

\[
E_f = E_{f, NC} = E_f' + \left( x_d - x_d' \right) \frac{P_e}{E} \tan \delta \frac{\Delta \omega}{\omega_0} + \frac{P_e}{E_0} \frac{\omega_0}{M} \left( 1 + c_1 c_2 \right) c_3 \Delta \delta + \frac{M}{\omega_0} \left( 1 + c_1 c_2 + \left( c_3 - \frac{D}{M} \right) \left( c_1 + c_2 - \frac{D}{M} \right) \right) \Delta \omega - \left( c_1 + c_2 + c_3 - \frac{D}{M} \right) \Delta P_e
\]  

(18)

and SVC control law

\[
u_{B, NC}(t) = \frac{1}{k_B} \left[ B_L(t) - B_{L0} + \frac{c_B T_B [y_1 y_2 (B_L(t) - B_C) + 1]}{P_e} \right] \]  

(19)

with gain \( c_B > 0 \). It is noticed that in (19), the time delay inserted from the \( z_3 \) measurement and feedback denoted by \( \tau(t) \) is taken into account, and the following delayed ODE is obtained:

\[
\dot{z}_3 = -c_3 z_3(t) - \frac{ac_B}{X} z_3(t - \tau(t)) \\
z_3(\theta) = \phi(\theta), \ \forall \theta \in E_0
\]  

(20)

where \( \phi : E_0 \rightarrow R \) is a continuous initial function with bounded norm defined in

\[
E_0 = \{ t \in R | \eta - \tau(\eta) \leq 0, \eta \geq t_0 \}
\]

The delay \( \tau(t) \) is assumed to be bounded with the bounded rate of change, that is, \( \tau \leq \tau(t) \leq \tilde{\tau} \) and \( \dot{\tau}(t) \leq \eta \) for some \( \eta, \tilde{\tau} > 0 \). The delayed term in (19) is the result of the fact that the variable \( z_3(t) \) does not involve local SVC measurements, but uses distant, and thus delayed, measurements from the generator. Thus, at time \( t \), the \( z_3(t - \tau(t)) \) is available for use in the SVC controller.

4. Overall System Stability Analysis

An analysis will be carried out next to prove that, under certain conditions on the magnitude of the time-delay, the error variable \( z_3 \) converges exponentially fast to zero.

It is worth noting that all solutions of (20) are also solutions of

\[
\dot{z}_3(t) = -\left( c_3 + \frac{ac_B}{X} \right) z_3(t) + \frac{ac_B}{X} \int_{s-\tau}^{t} c_3 z_3(s) \left( \frac{ac_B}{X} z_3(s - \tau(s)) \right) ds.
\]  

(21)

The solution of (21) is given by

\[
z_3(t) = \exp \left[ -\left( c_3 + \frac{ac_B}{X} \right) \right] \phi(0) - \frac{ac_B}{X} \int_{0}^{t} e^{-(c_3 + \frac{ac_B}{X})(t-s)} \int_{\theta-\tilde{\tau}}^{\theta} \left( c_3 z_3(s) + \frac{ac_B}{X} z_3(s - \tau(s)) \right) ds d\theta
\]  

(22)
which in turn yields

\[ |z_3(t)| \leq \exp\left[-\left(c_3 + \frac{ac_B}{X}\right)\right] \sup_{\theta \in E_0} |\phi(\theta)| + \frac{ac_B}{X} \int_0^t \exp\left[-\left(c_3 + \frac{ac_B}{X}\right)(t - \theta)\right] \int_{\theta - \tau(\theta)}^{\theta} (c_3|z_3(s)| + \frac{ac_B}{X}|z_3(s - \tau(s))|) ds d\theta. \]  

Consider now the functional differential equation

\[ \dot{y}(t) = -\left(c_3 + \frac{ac_B}{X}\right) y(t) + q(t) y(t - \tau(t)) \]  

where

\[ q(t) = \left(c_3 + \frac{ac_B}{X} - \frac{\sigma}{\tau(t)}\right) \exp\left(-\int_{t - \tau(t)}^{t} \frac{d\theta}{\tau(\theta)}\right) \]  

and \(0 < \sigma < \tau(c_3 + ac_B/X)\). By direct substitution, one can see that the solution of (24) is

\[ y(t) = C_0 \exp\left(-\sigma \int_0^t \frac{ds}{\tau(s)}\right). \]  

Using the mean value theorem repeatedly, one concludes that there exist constants \(0 < \theta_2 < \theta_1 < 1\), such that

\[ \int_{t - \tau(t)}^{t} \frac{d\theta}{\tau(\theta)} = \frac{\tau(t)}{\tau(t - \theta_1 \tau(t))} = \frac{\tau(t)}{\tau(t - \theta_1 \tau(t) \tau(t - \theta_2 \tau(t))} \leq \frac{1}{1 - \eta}. \]  

Thus, from (25) and (27), we arrive at

\[ q(t) \geq \left(c_3 + \frac{ac_B}{X} - \frac{\sigma}{\tau}\right) \exp\left(-\frac{\sigma}{1 - \eta}\right). \]  

We will prove next that, for a proper selection of \(C_0, \sigma > 0\), the function \(y(t)\) is an upper bound of \(|z_3(t)|\). Alternatively, \(y(t)\) can be written as

\[ y(t) = C_0 \exp\left[-\left(c_3 + \frac{ac_B}{X}\right) t\right] + \int_0^t \exp\left[-\left(c_3 + \frac{ac_B}{X}\right)(t - \theta)\right] q(\theta) y(\theta - \tau(\theta)) d\theta. \]  

A comparison of \(|z_3(t)|\) with \(y(t)\) will yield the desired stability result. To this end, we define the error variable as

\[ e(t) := |z_3(t)| - y(t) \]  

For \(e(t)\), from (23) and (29), we have the following:

\[ e(t) \leq \exp\left[-\left(c_3 + \frac{ac_B}{X}\right) t\right] \sup_{\theta \in E_0} |\phi(\theta)| - C_0 \]  

\[ + \frac{ac_B}{X} \int_0^t \exp\left[-\left(c_3 + \frac{ac_B}{X}\right)(t - \theta)\right] \int_{\theta - \tau(\theta)}^{\theta} (c_3|z_3(s)| + \frac{ac_B}{X}|z_3(s - \tau(s))|) ds d\theta \]  

\[ - \int_0^t \exp\left[-\left(c_3 + \frac{ac_B}{X}\right)(t - \theta)\right] q(\theta) y(\theta - \tau(\theta)) d\theta. \]
The above inequality can be written equivalently as

\[
e(t) \leq \exp \left[-(c_3 + \frac{ac_B}{X})(t - \sup_{\theta \in E_0} \phi(\theta) - C_0)\right]
+ \frac{ac_B}{X} \int_0^{t} \exp \left[-(c_3 + \frac{ac_B}{X})(t - \theta)\right] \int_{\theta - \tau(\theta)}^{\theta} (c_3\phi(s) + \frac{ac_B}{X}\phi(s - \tau(s))) ds d\theta
+ \int_0^{t} \exp \left[-(c_3 + \frac{ac_B}{X})(t - \theta)\right] \left[(c_3y(s) + \frac{ac_B}{X}y(s - \tau(s))) ds - q(\theta)\phi(\theta - \tau(\theta))\right] d\theta.
\]

(32)

The integral term within (32) can be bounded as follows

\[
\frac{ac_B}{X} \int_{\theta - \tau(\theta)}^{\theta} \left[(c_3y(s) + \frac{ac_B}{X}y(s - \tau(s))) ds - q(\theta)\phi(\theta - \tau(\theta))\right] d\theta
\]

(33)

= \frac{ac_B}{X} \int_{\theta - \tau(\theta)}^{\theta} \left[c_3\exp\left(-\frac{a}{\tau(\eta)}\right) + \frac{ac_B}{X}\exp\left(-\int_{0}^{\tau(\theta)} \frac{d\lambda}{\tau(\lambda)}\right)\right] ds

\]

\[
= \frac{ac_B}{X} \int_{\theta - \tau(\theta)}^{\theta} \left[c_3 + \frac{ac_B}{X}\exp\left(-\int_{0}^{\tau(\theta)} \frac{d\lambda}{\tau(\lambda)}\right)\right] d\theta
\]

\[
\leq \frac{ac_B}{X} \left[c_3 + \frac{ac_B}{X}\exp\left(-\int_{0}^{\tau(\theta)} \frac{d\lambda}{\tau(\lambda)}\right)\right] d\theta
\]

\[
\leq \frac{ac_B}{X} \left[c_3 + \frac{ac_B}{X}\exp\left(-\int_{0}^{\tau(\theta)} \frac{d\lambda}{\tau(\lambda)}\right)\right] d\theta
\]

(34)

Consider now the equation

\[
\frac{ac_B}{X} \left(c_3 + \frac{ac_B}{X}\exp\left(-\frac{a}{\tau(\eta)}\right)\right) \Phi = \exp\left(-\frac{a}{\tau(\eta)}\right) \left(c_3 + \frac{ac_B}{X}\frac{a}{\tau(\eta)}\right).
\]

(35)

The left hand side (l.h.s) of (34) is a strictly increasing function of \(\sigma\), whereas the right hand side (r.h.s) is a strictly decreasing function of \(\sigma\) in \([0, \infty)\). Thus, a unique, positive solution of (34) exists if and only if the value of the r.h.s. is greater than the value of the l.h.s. for \(\sigma = 0\). This condition yields

\[
\frac{ac_B}{X} \cdot \tau < 1
\]

(36)

Hence, inequality (35) provides an upper bound on the time delays that can be allowed.

Furthermore, using (26) and (28), we can prove that

\[
\frac{ac_B}{X} \int_{\theta - \tau(\theta)}^{\theta} \left[c_3y(s) + \frac{ac_B}{X}y(s - \tau(s))\right] ds
\]

\[
\leq \exp\left(-\int_{0}^{\tau(\theta)} \frac{d\lambda}{\tau(\lambda)}\right) \left[c_3 + \frac{ac_B}{X} - \frac{a}{\tau(\eta)}\right] y(\theta - \tau(\theta)) \leq q(\theta) y(\theta - \tau(\theta)).
\]

(37)

If we choose the initial condition \(C_0\), such that

\[
y(t) \geq \left|\phi(t)\right|, \forall t \in E_0
\]

\[
C_0 \geq \sup_{\theta \in E_0} \left|\phi(\theta)\right|
\]
then from (32), (36), and (37), we have
\[
e(t) \leq \frac{\alpha \bar{c}_{B}}{X} \int_{0}^{t} \exp \left[ - \left( c_{3} + \frac{\alpha \bar{c}_{B}}{X} \right)(t - \theta) \right] \int_{\theta - \tau(\theta)}^{\theta} \left( c_{3} \varepsilon(s) + \frac{\alpha \bar{c}_{B}}{X} \varepsilon(s - \tau(s)) \right) ds d\theta.
\]
(38)

while using (37) in (30) results in
\[
e(t) \leq 0, \quad \forall t \in \mathbb{E}_0.
\]
(39)

A contradiction argument can be used to prove that \(e(t) \leq 0, \quad \forall t > 0\). Assume the opposite, that is, \(e(t) > 0\) for some \(t > 0\). Then, for some sufficiently small \(\varepsilon > 0\), there exists \(t' = \inf\{t > 0: e(t) \geq \varepsilon\}\), for which \(e(t') = \varepsilon\). From (38) and (35), we have that
\[
e(t') \leq \frac{\alpha \bar{c}_{B}}{X} \int_{0}^{t'} \exp \left[ - \left( c_{3} + \frac{\alpha \bar{c}_{B}}{X} \right)(t - \theta) \right] \int_{\theta - \tau(\theta)}^{\theta} \left( c_{3} \varepsilon(s) + \frac{\alpha \bar{c}_{B}}{X} \varepsilon(s - \tau(s)) \right) ds d\theta
\]
(40)

which yields the desired contradiction. Hence, \(e(t) \leq 0, \quad \forall t \geq 0\), and thus
\[
|z_3(t)| \leq C_0 \exp \left( -\sigma \int_{0}^{t} \frac{dr}{\tau(r)} \right) \leq M' \sup_{\theta \in \mathbb{E}_0} \left\| \phi(\theta) \right\| \exp \left( -\frac{\sigma t}{\tau(t)} \right) \leq M' \sup_{\theta \in \mathbb{E}_0} \left\| \phi(\theta) \right\| \exp \left( -\frac{\sigma t}{\tau(t)} \right) \forall t \geq 0
\]
(41)

that is, the error variable \(z_3(t)\) converges exponentially to zero. Furthermore, if we define the nonnegative function \(V_2 = (1/2)z_1^2 + (1/2)z_2^2\), then we have
\[
V_2 = -c_1z_1^2 - c_2z_2^2 - \frac{\alpha \bar{c}_{B}z_3}{M} \leq -c_1z_1^2 - c_2z_2^2 - \frac{\alpha \bar{c}_{B}}{M} \sup_{\theta \in \mathbb{E}_0} \left\| \phi(\theta) \right\| \exp \left( -\frac{\sigma t}{\tau(t)} \right)z_2
\]
(42)

with \(c := \min\{c_1, c_2 - \varepsilon\} > 0\) for some \(0 < \varepsilon < c_2\).

The above differential inequality can be set in integral form as follows:
\[
V_2(t) \leq V_2(0) + \frac{\tau}{\delta \varepsilon} \left( \frac{\alpha \bar{c}_{B}M'}{M} \right)^2 \sup_{\theta \in \mathbb{E}_0} \left\| \phi(\theta) \right\|^2 \left( 1 - e^{-2\alpha t / \tau} \right) - 2\varepsilon \int_{0}^{t} V_2(s) ds.
\]
(43)
Applying the Gronwall–Bellman Lemma in (43), we obtain
\[
V_2(t) \leq V_2(0) + \frac{\tau}{8\pi e} \left( \frac{a_0 M'}{M} \right)^2 \sup_{\theta \in \Theta_0} \left\{ |\phi(\theta)|^2 \right\} \left[ 1 - e^{-2\omega t/\tau} \right] \\
-2T_0 \int_{0}^{t} e^{-2\zeta(t-s)} \left[ V_2(0) + \frac{T}{8\pi e} \left( \frac{a_0 M'}{M} \right)^2 \sup_{\theta \in \Theta_0} \left\{ |\phi(\theta)|^2 \right\} \left[ 1 - e^{-2\omega s/\tau} \right] \right] ds \\
= V_2(0) + \frac{T}{8\pi e} \left( \frac{a_0 M'}{M} \right)^2 \sup_{\theta \in \Theta_0} \left\{ |\phi(\theta)|^2 \right\} \left[ 1 - e^{-2\omega t/\tau} \right] \\
-2T_0 \int_{0}^{t} e^{-2\zeta(t-s)} ds \\
+2T_0 \frac{T}{8\pi e} \left( \frac{a_0 M'}{M} \right)^2 \sup_{\theta \in \Theta_0} \left\{ |\phi(\theta)|^2 \right\} \left[ e^{-2\zeta(t-s)} - e^{-2\omega s/\tau} \right] ds. 
\] (44)

which yields
\[
V_2(t) \leq V_2(0)e^{-2\zeta t} + \frac{T}{8\pi e} \left( \frac{a_0 M'}{M} \right)^2 \sup_{\theta \in \Theta_0} \left\{ |\phi(\theta)|^2 \right\} \left[ e^{-2\zeta t} - e^{-2\omega t/\tau} \right] \\
+2T_0 \frac{T}{8\pi e} \left( \frac{a_0 M'}{M} \right)^2 \sup_{\theta \in \Theta_0} \left\{ |\phi(\theta)|^2 \right\} \left[ e^{-2\zeta t} - e^{-2\omega t/\tau} \right] ds. 
\] (45)

Hence, it holds true that
\[
V_2(t) \leq \begin{cases} 
V_2(0)e^{-2\zeta t} + \frac{T}{8\pi e} \left( \frac{a_0 M'}{M} \right)^2 \sup_{\theta \in \Theta_0} \left\{ |\phi(\theta)|^2 \right\} \left[ e^{-2\zeta t} - e^{-2\omega t/\tau} + 2T_0 e^{-2\zeta t} \right], & \text{if } \zeta = \sigma/\tau \\
V_2(0)e^{-2\zeta t} + \frac{T}{8\pi e} \left( \frac{a_0 M'}{M} \right)^2 \sup_{\theta \in \Theta_0} \left\{ |\phi(\theta)|^2 \right\} \left[ e^{-2\zeta t} - e^{-2\omega t/\tau} \right], & \text{if } \zeta \neq \sigma/\tau 
\end{cases} 
\] (46)

which guarantees exponential stability of the equilibrium $z_1 = z_2 = 0$. Thus, the following theorem has been proven.

**Theorem 1.** Consider the SGIB with SVC system defined by (1)–(6), (11), and (12). If the generator excitation input is selected as in (18) and the SVC control as in (19) with time varying delay bound satisfying (35), then all closed-loop signals remain bounded and the power angle deviations exponentially converge to zero.

The previous analysis has clearly shown that distant delayed measurements can be used in the static var compensator control law for improving the transient stability of SGIB power system.

**5. Coordinated Frequency and Voltage Control**

The proposed nonlinear feedback linearizing controls ensure convergence of the power angles to their pre-fault values. However, this property is not desirable for a network changing topology because, in this case, the steady state voltages might deviate from the nominal ones. To address this issue, we adopt and modify the approach firstly used in [22], where a coordinated voltage and frequency scheme was proposed. The coordinated control scheme retains the transient behavior of the nonlinear controls (faster and better than the AVR/PSS), while ensuring voltage regulation similar to an AVR/PSS. In the coordinated control scheme, the nonlinear controller takes over right after the fault, switching to an AVR/PSS controller after the large frequency deviations have been eliminated. This controller transition is implemented with a soft switching algorithm based on the frequency deviations $\Delta \omega$. Specifically, the following simple Takagi–Sugeno–Kang fuzzy rules are employed for the controller selection:

\[
\text{IF } |\Delta \omega| \text{ is LARGE THEN } E_f = E_{f, NC} \\
\text{IF } |\Delta \omega| \text{ is SMALL THEN } E_f = E_{f, AVR,PSS}
\]
where
\[
E_{f, \text{AVR/PSS}} = E_{f0} + \frac{K_a}{T_d + 1} \left( -\Delta V_t + \frac{T_1 s + 1}{T_2 s + 1} \frac{T_i s + 1}{T_p s + 1} K_{\text{PSS}} \Delta \omega \right)
\]  
(47)

By choosing the membership functions
\[
\mu_1(\Delta \omega) = \frac{1}{1 + e^{-38(|\Delta \omega| - 0.253)}} , \quad \mu_2(\Delta \omega) = 1 - \frac{1}{1 + e^{-38(|\Delta \omega| - 0.253)}}
\]  
(48)

which represent the linguistic values LARGE and SMALL for the fuzzy variable $\Delta \omega$ (see Figure 5), the control input takes the following form:
\[
E_f = \mu_1(\Delta \omega) E_{f, \text{NC}} + \mu_2(\Delta \omega) E_{f, \text{AVR/PSS}}
\]  
(49)

![Figure 5. The membership functions.](image)

This switching approach can also be utilized in the SVC compensator design. Specifically, a coordinated control strategy can be used in the SVC, which ensures that, initially, the power angle generator oscillations are rapidly damped, and then the SVC bus voltage is regulated towards its nominal value. To this end, a soft switching approach is adopted. The controllers switch when the large power angle deviations have been sufficiently mitigated so that the ancillary action of the SVC controller is no longer needed. The magnitude of the frequency deviation can serve as a switching criterion. In the new steady state, the SVC controller is transformed to a PI controller of the following form:

\[
u_{B,V}(t) = k_p \Delta V_B(t) + k_i \int_0^t \Delta V_B(\tau) d\tau
\]  
(50)

and the combined control law is then
\[
u_B(t) = \mu_1(\Delta \omega(t - \tau(t))) u_{B,NC}(t) + \mu_2(\Delta \omega(t - \tau(t))) u_{B,V}
\]  
(51)

Obviously, the control law that employs delayed generator measurements can improve the transient stability only if the magnitude of the communication delays is small enough. After a careful examination of the simulation studies and taking into account the fact that the first peak in the oscillatory power angle response occurs at about 1 s after fault, a critical time of approximately 250 ms after fault can be defined. All measurements after a fault and up to this time can be used in the scheme we described above. Thus, the control law (51) should be modified to ensure that, for delays larger than 250 ms, a classical voltage PI is used, whereas, for delays smaller than or equal to 250 ms, the proposed nonlinear controller is used.
The nonlinear excitation controller parameters are chosen as

\[ E_{\text{2020}} \text{ and } \text{simple AVR} \]

the coordinated nonlinear stabilizer with the AVR stabilizer with the AVR.

Comparisons are made between three different cases. In particular, the proposed coordinated nonlinear stabilizer with the AVR/PSS and PI SVC controller (case 1: C-NC-AVR/PSS+SVC PI) is compared with the coordinated nonlinear stabilizer with the AVR/PSS controller (case 2: C-NC-AVR/PSS) and the simple AVR/PSS (case 3) controller.

\[ K_t = 1 \text{ and } K_j = 10. \]

A symmetrical three-phase fault occurs at time \( t = 3 \text{ sec} \) in the middle of one of the two lines connecting the generator and SVC buses (\( k = 0.5 \)). Breakers open after 200 ms and the line remains open. Both the power angle response (Figure 6) and the terminal voltage response (Figure 7) demonstrate the effectiveness of the SVC compensator in improving the transient stability of the power system. Comparisons are made between three different cases. In particular, the proposed coordinated nonlinear stabilizer with the AVR/PSS and PI SVC controller (case 1: C-NC-AVR/PSS+SVC PI) is compared with the coordinated nonlinear stabilizer with the AVR/PSS controller (case 2: C-NC-AVR/PSS) and the simple AVR/PSS (case 3) controller.
Figure 8 indicates that its action is not sufficient to avoid loss of synchronization for a fault that occurs close to the generator. The C-NC-AVR/PSS+C-SVC controller on the other hand can effectively regulate voltages at the generator and SVC bus to their nominal values.

Even though the PI SVC controller can help in reducing the undesired oscillations after a fault, Figure 7 indicates that the case 2 controller provides a better response than that of case 3. Figure 6 shows that the power angle oscillations after the simulated large fault are significantly reduced by the action of the proposed coordinated nonlinear stabilizer of case 1. For the other two, it is seen that the case 2 controller provides a better response than that of case 3. Figure 7 indicates the superior performance of the proposed stabilizer in improving the transient stability of the power system. Comparisons are made between three different cases. In particular, the proposed coordinated nonlinear stabilizer with the AVR/PSS and PI SVC controller (case 2: C-NC-AVR/PSS+SVC PI) and the simple AVR/PSS (case 3) controller.

For the case of a more severe fault closer to the generator bus ($k = 0.21$), which is again removed after 200 ms, we compare the two control schemes: the coordinated nonlinear stabilizer with AVR/PSS and PI SVC controller (C-NC-AVR/PSS+SVC PI) and the coordinated nonlinear stabilizer with AVR/PSS and coordinated SVC control (C-NC-AVR/PSS+C-SVC).

Even though the PI SVC controller can help in reducing the undesired oscillations after a fault, Figure 8 indicates that its action is not sufficient to avoid loss of synchronization for a fault that occurs

Figure 6. Generator power angle responses (in degrees).

so close to the generator. The C-NC-AVR/PSS+C-SVC controller on the other hand can efficiently return the system to the equilibrium point, avoiding loss of synchronism.

Figures 9–11 show the generator terminal voltage response, the SVC bus voltage response, and the varying susceptance in the SVC compensator, respectively, under the proposed C-NC-AVR/PSS+C-SVC and C-NC-AVR/PSS+SVC PI controllers. Unstable oscillations for $V_t, V_{SVC}$ occur under the C-NC-AVR/PSS+SVC PI controller, whereas the C-NC-AVR/PSS+C-SVC controller can effectively regulate voltages at the generator and SVC bus to their nominal values.

Figure 8. Power angle deviations (in degrees).

7. Conclusions

A new coordinated excitation and SVC control is proposed for regulating the output voltage and improving the transient stability of a synchronous generator infinite bus (SGIB) power system. By regulating the SVC susceptance using distant from the generator, and thus delayed, measurements, the SVC can potentially improve the overall transient performance and stability. The time delays that further complicate the rigorous analysis conducted are taken into account and impose the limits and conditions that are adequate for the proposed controller to be efficient and stable. The scheme is completed by a soft-switching mechanism used to recover the output voltage level at the terminal bus and the SVC bus after the large power angle deviations have been eliminated.

Author Contributions: The first author, H.E.P., contributed to the deployment of the novel nonlinear design and analysis, whereas the second author, A.T.A., contributed to the validation of the proposed method. All authors have read and agreed to the published version of the manuscript.
During the fault, the network topology is shown in Figure 3. Then, applying Ohm’s current law at node 0, we obtain

\[
I = \frac{E_q' \omega \delta - V_0}{j(x_d' + x_{T1} + \frac{x_2}{2})} = \frac{V_0}{j(x_{T2} + \frac{1}{B_i-B_c})} + \frac{V_0 - 1}{j\omega}\]

which yields

\[
V_0 = \frac{\bar{X}}{(x_d' + x_{T1} + \frac{x_2}{2})}E_q' \omega \delta + \frac{\bar{X}}{2} \text{ with } \bar{X} = \left(\frac{1}{x_d' + x_{T1} + \frac{x_2}{2}} + \frac{1}{x_{T2} + \frac{1}{B_i-B_c}} + \frac{1}{2}\right)^{-1}
\]

After some further calculations, one obtains for the electric power

\[
P_e = \text{Re}[E_q' \omega \delta \cdot \Gamma] = \frac{E_q' \sin \delta}{\frac{2\pi}{X}(x_d' + x_{T1} + \frac{x_2}{2})} := \frac{E_q' \sin \delta}{X}
\]

where

\[
X = \frac{2\pi}{X}(x_d' + x_{T1} + \frac{x_2}{2}) = x'_d + x_{T1} + \frac{x_2}{2} + \frac{x_2}{2}(x_d' + x_{T1} + \frac{x_2}{2})(x_{T2} + \frac{1}{B_i-B_c})^{-1}
\]

During the fault, the network topology is shown in Figure 3. Then, applying Ohm’s current law at node 0, we have that

\[
I = \frac{E_q' \omega \delta - V_0}{j(x_d' + x_{T1})} = \frac{V_0}{j(x_{T1} + \frac{1}{B_i-B_c})} + \frac{V_0 - V_1}{j\omega}
\]

Similarly, for node 1, it holds that

\[
\frac{V_0 - V_1}{jx_{L1}} = V_1 \left[\frac{1}{j(1-k)x_{L1}} + \frac{1}{j(x_{T2} + \frac{1}{B_i-B_c})}\right] + \frac{V_1 - 1}{j\omega}
\]
The above equation yields
\[
V_1 = \frac{X_1}{s_{L1}} V_0 + \frac{X_1}{s_{L2}} \text{ where } X_1 := \left[ \frac{1}{s_{L1}} + \frac{1}{(1-k)s_{L1}} + \frac{1}{s_{L2}} + \frac{1}{s_{L2} + \frac{1}{R_L - R_C}} \right]^{-1}
\]

The voltage \(V_0\) can then be calculated as
\[
V_0 = \frac{\bar{X}_2}{x'_d + x_{T1}} E'_q \zeta \delta + \frac{\bar{X}_1 \bar{X}_2}{x'_d + x_{T1} + \frac{1}{s_{L1}} + \frac{1}{x'_d + x_{T1}}} \text{ where } \bar{X}_2 := \left( \frac{1}{s_{L1}} + \frac{1}{k x_{L1}} + \frac{1}{x'_d + x_{T1}} - \frac{\bar{X}_1}{s_{L1}} \right)^{-1}
\]

After some further calculations, one obtains
\[
I = \frac{E'_q \zeta \delta - V_0}{j(x'_d + x_{T1})} = \left( 1 - \frac{\bar{X}_2}{x'_d + x_{T1}} \right) \frac{E'_q \zeta \delta}{j(x'_d + x_{T1})} - \frac{2\bar{X}_1 \bar{X}_2}{\beta_{L1} \beta_{L2} (x'_d + x_{T1})}
\]

and then the electric power is
\[
P_e = \text{Re} \left[ E'_q \zeta \delta \cdot I^* \right] = \frac{E'_q \sin \delta}{\bar{X}} :\bar{X} = \frac{E'_q \sin \delta}{X}
\]

where
\[
X = \frac{x'_d}{2 x_{L1}} \left( x'_d + x_{T1} \right)
= \left[ \frac{x_{L1}}{x_{L1} x_{T1}} + \frac{(k+1)x_{L2}}{2k} \left( x'_d + x_{T1} \right) \right] x_{L1}
= \left[ \frac{x_{L1}}{2 x_{L2}} + \frac{2x_{L2}}{x_{L1} x_{T1}} - \frac{1}{x_{L1} x_{T1}} \left( x'_d + x_{T1} \right)^{-1} + \frac{1}{x_{L1} x_{T1}} \right]^{-1} \left( x_{T2} + \frac{1}{R_L - R_C} \right)^{-1}
\]

The post-fault network topology is depicted in Figure 4. One can see that this is identical to the pre-fault case with the exception of the \(j \beta_{L1}\) reactance in place of \(j \beta_{L1}/2\). Thus, the total reactance in this case is
\[
X = x'_d + x_{T1} + x_{L1} + \frac{x_{L2}}{2} + \frac{x_{L2}}{2} \left( x'_d + x_{T1} + x_{L1} \right) \left( x_{T2} + \frac{1}{R_L - R_C} \right)^{-1}
\]
