Abstract

The problem of obtaining canonical Hamiltonian structures from the equations of motion, without any knowledge of the action, is studied in the context of the spatially flat Friedmann, ’Robertson’, and Walker models. Modifications to the Raychaudhuri equation are implemented independently as quadratic and cubic terms of energy density without introducing additional degrees of freedom. Depending on their sign, modifications make gravity repulsive above a curvature scale for matter satisfying strong energy conditions, or more attractive than in the classical theory. The canonical structure of the modified theories is determined by demanding that the total Hamiltonian be a linear combination of gravity and matter Hamiltonians. In the quadratic repulsive case, the modified canonical phase space of gravity is a polymerized phase space with canonical momentum as inverse a trigonometric function of the Hubble rate; the canonical Hamiltonian can be identified with the effective Hamiltonian in loop quantum cosmology. The repulsive cubic modification results in a ‘generalized polymerized’ canonical phase space. Both the repulsive modifications are found to yield singularity avoidance. In contrast, the quadratic and cubic attractive modifications result in a canonical phase space in which canonical momentum is nontrigonometric and singularities persist. Our results hint at connections between the repulsive/attractive nature of modifications to gravity arising from the gravitational sector and polymerized/non polymerized gravitational phase space.

Keywords: loop quantum cosmology, modified gravity scenarios, inverse methods
1. Introduction

Suppose one desires a particular form of dynamical equations in a modified theory of gravity, and has no knowledge of the Lagrangian or the Hamiltonian structure of the theory. Then, what properties of the canonical Hamiltonian structure can one deduce directly from dynamical equations? What does a cosmological dynamical equation in a modified theory of gravity tell us about the underlying canonical phase space? From an inverse point of view, these are fundamental questions that can help in deciphering the right Hamiltonian (and the action) for a theory that yields desired physics. As an example, we may demand that there be a modified theory of gravity free of singularities without violating weak energy condition. Starting from the modified dynamical equations in general relativity (GR), which avoid singularities for positive-definite energy density, how do we systematically derive the corresponding canonical Hamiltonian without any knowledge of the action?

The goal of this paper is to address these questions for spatially flat homogeneous and isotropic models in modified-gravity scenarios. Due to homogeneity, the diffeomorphism constraint is trivially satisfied and the only nontrivial constraint is the Hamiltonian constraint that vanishes weakly. The modified cosmological theories we consider are assumed to have the same degrees of freedom as classical cosmology without any violation of the conservation law of matter energy and general covariance. The modification to cosmological dynamics is assumed to arise purely from the gravitational sector. Matter is assumed to be coupled minimally. We focus our attention on the conditions imposed by the properties of gravity, which make it repulsive above a curvature scale without violation of energy conditions or more attractive than GR, on the possible forms of the underlying canonical Hamiltonian structures producing them. Our discussion will be based on the existence of the total Hamiltonian as a linear combination \( \mathcal{H} = \mathcal{H}_g + \mathcal{H}_m \) of gravity and matter Hamiltonians. To find the Hamiltonian in this form we rely on the fact that the matter Hamiltonian is given by \( \mathcal{H}_m = \rho V \), where \( \rho \) is the energy density of matter and \( V \) is the cube of the scale factor \( \alpha \), and that in the modified-gravity scenarios considered in our analysis matter Hamiltonian is not affected.

The problem we want to solve relates to classical mechanics. It is of great importance in mechanics to find the procedure for systematically arriving at the Lagrangian and the Hamiltonian of a system starting from its equations of motion (see for e.g., [1–11]). Conventionally, we guess a form for the Lagrangian from deep physical intuition (and obtain the corresponding Hamiltonian), and then demonstrate the correctness of the Lagrangian (or the Hamiltonian) by verifying that the resulting Lagrange’s equation of motion (or the Hamilton’s equations) is indeed the known equations of motion. However, when starting from equations of motion different strategies exist to find the Lagrangian and Hamiltonian. An action can be obtained using Helmholtz conditions in the the inverse problem of calculus of variations from which a Hamiltonian can be derived [1]. A Hamiltonian can also be obtained from equations of motion by passing the Lagrangian using constants of motion and symmetry vectors [9–11]. For example, in the case of the electromagnetic field, the form of Lagrangian density is conventionally guessed from covariance. Verification of this guess is demonstrated by showing that the Lagrange’s equations yield the Maxwell equations. However, the Lagrangian density can be systematically derived from Maxwell’s equations using a reverse procedure based on Hamilton’s principle [7]. As another example, an action principle for extended objects with arbitrary multipole moments in general relativity can be obtained by expanding the stress energy tensor in a Taylor series and suitable contractions of resulting terms with space-time curvature components [12], whereas similar action upto the dipole moment has been obtained using inverse variational procedure for a spinning particle [13].
Similarly, non-Lagrangian construction of Hamiltonian structures has been performed in a variety of cases, such as for Korteweg de Vries equation using a symmetry vector and a constant of motion [10] and for motion of projectiles with resistance using one constant of motion [11].

Our approach to the discussion of the problem posed in this work was inspired by an analog of the second-order equation of motion in the cosmological models, which is the Raychaudhuri equation for the scale factor of the Universe. For matter with a given equation of state, the scale factor $a$ and its time derivative encode all dynamics that can be obtained from the Raychaudhuri equation. This equation plays an important role in gravitational theories. It is central in understanding geodesic flows and singularity theorems, and as a ‘force law’ it reveals the attractive ($\ddot{a} < 0$) or repulsive ($\ddot{a} > 0$) nature of gravity. Given the classical Raychaudhuri equation or one of its avatars in modified gravity, the sign of $\ddot{a}$ can be changed by choosing the appropriate matter. For example, in classical cosmology for matter that obeys (or violates) the strong energy condition, the classical Raychaudhuri equation yields $\ddot{a} < 0$ (or $\ddot{a} > 0$). However, in general for modified-gravity scenarios the repulsive/more attractive nature of gravity deduced from Raychaudhuri equation is not restricted to the choice of matter. Due to an interplay of gravitational and matter sectors, the Raychaudhuri equation in a modified-gravity scenario may take a form such that the sign of $\ddot{a}$ can become positive even for matter that does not violate the strong energy condition, and vice versa. It is in this latter sense that we discuss the attractive/repulsive property of modified gravity in our analysis. In particular, a modification of the Raychaudhuri equation will be denoted repulsive (attractive) if it yields $\ddot{a} > 0$ ($\ddot{a} < 0$) for matter for which gravity is attractive in the classical theory.

We provide a straightforward analytical procedure to find the Hamiltonian in terms of canonical variables that requires no physical intuition other than the realization that it is useful to look for a constant of motion ($C$) in dynamics encoded by the Raychaudhuri equation. This constant of motion can then be identified with an intermediate Hamiltonian using Hojman’s analysis [11]. However, we show that the latter step is not sufficient to understand the Hamiltonian structure, in particular of the gravitational sector, because the intermediate Hamiltonian does not appear as a linear combination of gravity and matter Hamiltonian. The matter Hamiltonian, which is simply related to the energy density as $H_m = \rho a^3$, appears with a function of phase space or even with higher powers in modified scenarios. For example, in classical cosmology the intermediate Hamiltonian turns out to be of the form $C(a, p) = p^2/2m + V(a)$, where $p = \dot{a}$ is the conjugate momentum and $V(a)$ is a function of the scale factor. The potential term does not correspond to the matter Hamiltonian. Since this term is in this sense mixed, the ‘kinetic energy’ term can not be identified as the gravitational Hamiltonian. However, in the modified-gravity scenarios, this mixing gets more complicated and the potential term becomes a nonlinear function of the matter Hamiltonian and phase-space variables. This obstacle is overcome in our procedure by using the property that the total Hamiltonian vanishes. We are then able to write a Hamiltonian in the form $\mathcal{H}_g + \mathcal{H}_m$ and identify the canonical phase-space structure.

We consider four different types of modified Raychaudhuri equation and derive the resulting canonical phase-space structure and Hamiltonians. Modifications to the classical Raychaudhuri equation involve $\rho^2$ and $\rho^3$ terms, with positive as well as negative signs. For the positive sign modifications, $\ddot{a}$ changes sign above a certain energy density $\rho_0$. The scale $\rho_0$ is a parameter of the modified Raychaudhuri equation supposed to be fixed by the underlying theory. If we start with matter that leads to attractive gravity in GR, the modified Raychaudhuri equations with $+\rho^2$ and $+\rho^3$ modifications result in repulsive gravity for $\rho > \rho_0$. For this reason we call these modifications as repulsive quadratic and repulsive cubic modifications, respectively. The quadratic and cubic modifications with negative sign result in
gravity being universally more attractive than in GR for matter that results in classical attractive gravity. We label these modifications as attractive quadratic and attractive cubic modifications. For the repulsive modifications, we find the Hubble rate to be universally bounded, which signals a generic resolution of cosmological singularities [14]. For the quadratic repulsive case, we find the resulting canonical phase space to be polymerized. The canonically conjugate momentum to volume, which we choose as the generalized coordinate in all cases, turns out to be an inverse trigonometric function of the Hubble rate. The canonical Hamiltonian can be identified with the effective Hamiltonian in loop quantum cosmology with appropriate identification of energy-density scale at which gravity becomes repulsive [15, 16]. In the cubic repulsive case, canonical momentum is a hypergeometric function of the inverse trigonometric function of the Hubble rate. With similarities to the polymerized momentum, we label this momentum as a ‘generalized polymerized’ version of the one obtained in the quadratic repulsive case. Unlike the quadratic repulsive case whose cosmological dynamics has been extremely well studied in the framework of loop quantum cosmology [17], the cubic repulsive case is a new nonsingular cosmological model. In contrast to the repulsive modifications, attractive modifications do not yield conjugate momentum, which is an inverse trigonometric function and thus there is no polymerization in the phase space. Hubble rate is unbounded in these cases. Thus, there is a sharp distinction between the gravitational phase spaces of repulsive and attractive modifications.

This paper is organized as follows. In section 2, we illustrate our method to obtain a canonical Hamiltonian as a linear combination of gravitational and matter Hamiltonians directly from the Raychaudhuri equation for the case of classical cosmology. This example serves as a template for more general examples considered in the subsequent sections with some additional steps. Without any loss of generality, we consider the Raychaudhuri equation for the case of dust that has constant matter Hamiltonian. It may be noted that choosing different matter with a fixed equation of state leads to no change in procedure. It turns out that the resulting Hamiltonian yields evolution for matter for any equation of state by replacing the matter Hamiltonian accordingly. Following the procedure given in section 2, the canonical Hamiltonian structure for a \( \rho^2 \) modification with a positive sign in the classical Raychaudhuri equation is obtained in section 3. In section 4, we discuss the derivation of the canonical Hamiltonian structure for \( \rho^2 \) modification with a negative sign in the classical Raychaudhuri equation. To find the canonical Hamiltonian in the form \( H_g + H_m \), quadratic cases require obtaining roots of the vanishing of the intermediate Hamiltonian which is a quadratic equation in energy density. Cubic modification in energy density with a positive sign to the classical Raychaudhuri equation is analyzed in section 5 and its counterpart with a negative sign is discussed in section 6. In these cases, to obtain canonical phase space one finds roots of a roots of a cubic equation in \( \rho \). Physical roots are determined demanding energy density is real and positive. The latter requirement is needed only for the attractive modifications. Both of the repulsive cases, lead to dual roots covering different sectors of the gravitational phase space. The attractive modifications yield a single root which covers the entire range of energy density. We keep the conventions to discuss the phase space structures for different Hamiltonians same in section 3–6 (which follow the convention set in section 2). The manuscript concludes with a discussion in section 7.

2. Classical Hamiltonian from the Raychaudhuri equation

In this section, we illustrate the procedure for obtaining the Hamiltonian in terms of canonical variables from the Raychaudhuri equation in the spatially flat Friedmann–Robertson–Walker
Universe in classical GR. Key elements of the method we outline here, are used in subsequent sections for modified-gravity scenarios. The Raychaudhuri equation for a perfect fluid with energy density $\rho$ and pressure $P$ in classical FRW model is given by

$$\dot{a} = -\frac{4\pi G}{3} (1 + 3w) \rho a.$$  

(2.1)

Here $w$ is the equation of state $w = P/\rho$ and the ‘dot’ is the derivative with respect to proper time. The energy density is defined as $\rho = \mathcal{H}_m/V$, where $\mathcal{H}_m$ is the matter Hamiltonian and $V$, equal to $a^3$, denotes the volume of the Universe. Pressure is defined as $P = -\partial \mathcal{H}_m/\partial V$. The energy density and pressure satisfy the conservation law from the covariant conservation of the stress-energy tensor:

$$\dot{\rho} + 3H (\rho + P) = 0,$$  

(2.2)

where $H = \dot{a}/a$ is the Hubble rate.

For simplicity, let us consider the case of equation of state $w = 0$. In this case, the Raychaudhuri equation can be rewritten as

$$\dot{a} = -\frac{4\pi G}{3} \rho a.$$  

(2.3)

Then, using (2.2) we find that $\rho = \rho_0 (a_0/a)^3$, with $\rho_0$ and $a_0$ being constants of integration. Thus, for the case of dust the matter Hamiltonian is a constant $\mathcal{H}_m = \rho_0 a^3 = \rho_0 a_0^3$.

We are interested in finding the Hamiltonian $\mathcal{H}$ corresponding to equation (2.3) in terms of the canonical phase-space variables as a linear combination $\mathcal{H} = \mathcal{H}_g + \mathcal{H}_m$. The first step is to find a constant of the motion starting from the Raychaudhuri equation. This constant of the motion can be identified as a Hamiltonian [11]. However, this Hamiltonian serves only as an intermediate Hamiltonian in our analysis. As we will see, the intermediate Hamiltonian is not in the form of a linear combination of gravitational and matter Hamiltonians. The canonical Hamiltonian in the desired form is obtained using the property that the (intermediate) Hamiltonian vanishes due to general covariance.

To set the stage, let us consider a system described by the second-order dynamical equation

$$\ddot{q} = A(q)B(q),$$  

(2.4)

where $q$ denotes a generalized coordinate. The second-order equation can be written as two first-order equations as

$$\dot{x}_1 = x_2, \quad \dot{x}_2 = A(x_1)B(x_2),$$  

(2.5)

where $x_1$ and $x_2$ are defined as $x_1 = q$ and $x_2 = \dot{q}$, respectively. It is straightforward to see that equation (2.4) yields the following time-independent constant:

$$C(q, \dot{q}) = -\int A(q) dq + \int B^{-1}(q) \dot{q} d\dot{q}.$$  

(2.6)

Once a constant of motion is available, we use Hojman’s analysis, where it is shown that the Hamiltonian structure corresponding to the dynamical equation (2.4) is obtained by identifying $C(x_1, x_2)$ as a Hamiltonian, with $x_1$ and $x_2$ as the phase-space variables [11]. These variables satisfy the Poisson bracket $\{ x_1, x_2 \} = \mu (x_1, x_2)$. The function $\mu (x_1, x_2)$, denoted as $\mu$ in the following, will be determined from the consistency of the Hamiltonian evolution using the first-order equations of motion (2.5). It turns out that $\mu = B(x_1)$.

The above steps, i.e., finding a constant of the motion and treating that constant as a Hamiltonian, can be adapted to cosmological scenarios. However, the resulting Hamiltonian $C(x_1, x_2)$ does not turn out to be a linear combination of gravitational and matter.
Hamiltonians. To obtain such a Hamiltonian we use the fact that total Hamiltonian vanishes. We now apply our method to the classical Raychaudhuri equation (2.3). This equation is already in the form (2.4), with \( q \) identified as the scale factor. To express the classical Raychaudhuri equation (2.3) in terms of two first-order equations, we choose

\[ x_1 = a \quad \text{and} \quad x_2 = \dot{a}. \]  

Thus, equation (2.3) can be written as

\[ \dot{x}_1 = x_2 \quad \text{and} \quad \dot{x}_2 = -\frac{4\pi G}{3}\rho x_1. \]  

Comparing with (2.5), we obtain

\[ A(\dot{a}) = -\frac{4\pi G}{3}\rho \quad \text{and} \quad B(\dot{a}) = 1. \]  

Substituting \( A(\dot{a}) \) and \( B(\dot{a}) \) in (2.6) and using \( \rho = H_m/x_1^3 \) we obtain a constant of the motion in terms of \( x_1 \) and \( x_2 \):

\[ C(x_1, x_2) = \frac{x_2^2}{2} - \frac{4\pi G}{3} H_m x_1^{-1}. \]  

It is easy to check that \( C(x_1, x_2) \) leads to a consistent Hamiltonian evolution by computing the Hamilton equations:

\[ \dot{x}_1 = \mu \frac{\partial C}{\partial x_2} \quad \text{and} \quad \dot{x}_2 = -\mu \frac{\partial C}{\partial x_1}. \]  

These equations yield

\[ \dot{x}_1 = \mu x_2 \quad \text{and} \quad \dot{x}_2 = -\frac{4\pi G}{3} H_m \mu x_1^{-2}. \]  

Comparing the above equations with (2.8) shows that \( \mu = 1 \) for the Hamiltonian evolution generated by \( C(x_1, x_2) \). Hence, \( x_1 \) and \( x_2 \) are canonically conjugate phase-space variables for the Hamiltonian in equation (2.10). The phase-space variables \( x_1 \) and \( x_2 \) transform as scalars under time reparameterization and \( C(x_1, x_2) \) vanishes weakly due to general covariance [18].

Although \( C(x_1, x_2) \) yields a consistent Hamiltonian evolution, it is not in the form \( H_g + H_m \). To obtain a Hamiltonian in this form from \( C(x_1, x_2) \) we note that for a function on phase-space \( f(x_1, x_2) \), which is nondivergent and has nondivergent derivatives with respect to \( x_1 \) and \( x_2 \), \( f(x_1, x_2)C(x_1, x_2) \) is also a constant of the motion\(^3\). It is straightforward to see that by using the property that \( C(x_1, x_2) \) is a constant, \( C(x_1, x_2) \approx 0 \). To obtain a Hamiltonian in the desired form we multiply \( C(x_1, x_2) \) by \((-3/4\pi G)x_1 \) and obtain the Hamiltonian

\[ \mathcal{H} = -\frac{3}{8\pi G} x_2^2 x_1 + H_m, \]  

which weakly vanishes. This Hamiltonian yields the same space of solutions as \( C(x_1, x_2) \) and is in the form \( H_g + H_m \), with \( H_g \) identified as the term not containing \( H_m \) in the above equation.

Before we investigate the canonical structure of this Hamiltonian, it is interesting to note that using \( C(x_1, x_2) \approx 0 \), \( \mathcal{H} \) can be written as

\[ \mathcal{H} = -\rho a^3 + H_m \approx 0. \]  

\(^3\) The function \( f(x_1, x_2) \) can be interpreted as a different choice of lapse function.
The expression $H_m - \rho a^3$ is a constant of motion, which also follows independently from the matter-energy conservation law.

Having obtained the Hamiltonian in the desired form, we now find the canonical phase variables. It turns out that $x_1 = a$ and $x_2 = \dot{a}$ are a noncanonical pair under the Hamiltonian flow generated by $H$. The Hamilton equations corresponding to $H$ in equation (2.13) require $\{x_1, x_2\} = \mu = -(4\pi G/3)x_1^{-1}$. The canonical momentum corresponding to $x_1 = a$ can then be found by

$$p_a = \int d^4x \mu^{-1} x_2 = -\frac{3}{4\pi G} x_1 x_2.$$  \hspace{1cm} (2.15)

In terms of the canonical variables $(a, p_a)$, the Hamiltonian constraint can be written as

$$\mathcal{H}(a, p_a) = -\frac{2\pi G}{3} p_a^2 a^{-1} + H_m \approx 0.$$  \hspace{1cm} (2.16)

This gives the Hamiltonian for the spatially flat FRW model in classical general relativity for matter specified by $H_m$. An alternative way to write this Hamiltonian is by choosing volume as the generalized coordinate, i.e., $x_1 = V$, whose conjugate momentum is proportional to the Hubble rate: $p_V = -(4\pi G)^{-1}H$. In terms of canonical variables $(V, p_V)$, we obtain the Hamiltonian constraint as

$$\mathcal{H}(V, p_V) = -6\pi G p_V^2 V + H_m \approx 0.$$  \hspace{1cm} (2.17)

Thus, we obtain a Hamiltonian for the classical spatially flat FRW Universe in the form

$H + H_m$ in the canonical phase-space variables $a$ and $p_a$, as well as $V$ and $p_V$. In the following sections, we use $V$ as a generalized coordinate in the final Hamiltonian, and will suppress the volume subscript in its canonical momentum.

It is important to note that even though we started with dust as the matter content, the above Hamiltonian provides consistent Hamiltonian evolution for arbitrary matter content in classical cosmology. We could have started this computation for any matter with a fixed equation of state and reached the same canonical Hamiltonian. To obtain the dynamics of any given matter with a fixed equation of state, we have to choose the corresponding matter Hamiltonian in equation (2.17), or in any of the equivalent Hamiltonians derived above. It is easily seen that the vanishing of $H$ yields the classical Friedmann equation:

$$H^2 = \frac{8\pi G H_m}{3V}.$$  \hspace{1cm} (2.18)

We know from classical dynamics that the physical solutions resulting from the Hamiltonian in equation (2.17) are singular when the weak energy condition is satisfied.

3. The Raychaudhuri equation with a quadratic repulsive modification in energy density

In this section, we consider the first of our modifications to the classical Raychaudhuri equation and derive the corresponding canonical Hamiltonian structure. As before, we consider the case for dust and introduce a $\rho^2$ modification to equation (2.3) as

$$\dot{a} = -\frac{4\pi G}{3} \rho \left( 1 - \frac{\rho}{\rho_c} \right) a.$$  \hspace{1cm} (3.1)

Here $\rho_c$ is a constant-energy density whose value is to be determined by the underlying theory that is supposed to lead to the above equation. The modification is introduced without
affecting the underlying degrees of freedom of the gravitational and matter sectors. As in the classical theory, the modified theory of gravity is assumed to be generally covariant, whose total Hamiltonian $H$ weakly vanishes. The energy density $\rho$ satisfies the conservation law (2.2). At energy densities $\rho \ll \rho_c$, equation (3.1) is approximated by the Raychaudhuri equation in the classical theory (2.3). When the energy density becomes greater than $\rho_c$, the acceleration term in the Raychaudhuri equation changes sign. Gravity becomes repulsive at these scales. Note that the repulsive nature of gravity occurs without changing the equation of the state of matter.

Our goal is to find the Hamiltonian corresponding to the above modified Raychaudhuri equation in the form $H = H_g + H_m$. For dust, the matter Hamiltonian $H_m = \rho_m a^3 \dot{a}$ is a constant. To find the gravitational part of the Hamiltonian $H_g$ we employ the method outlined in the previous section for the classical Raychaudhuri equation. We start by choosing the gravitational phase-space variables as in the classical case (equation (2.7)):

$$x_1 = a \quad \text{and} \quad x_2 = \dot{a}.$$  

In terms of $x_1$ and $x_2$, the modified Raychaudhuri equation (3.1) results in

$$\dot{x}_1 = x_2, \quad \dot{x}_2 = -\frac{4\pi G}{3} \rho \left(1 - \frac{\rho}{\rho_c}\right)x_1.$$  

Comparing the above set with equation (2.5), we identify

$$A(x_1) = -\frac{4\pi G}{3} \rho \left(1 - \frac{\rho}{\rho_c}\right)x_1 \quad \text{and} \quad B(x_2) = 1.$$  

The constant of motion $C(x_1, x_2)$ can then be determined using equation (2.6). It turns out to be

$$C(x_1, x_2) = \frac{x_2^2}{2} - \frac{4\pi G}{3} \frac{H_m}{x_1^3} \left(1 - \frac{1}{4\rho_c} \frac{H_m}{x_1^3}\right) x_1^2$$  

where we have used $\rho = H_m/a^3$. It is straightforward to verify that this constant of motion serves as a Hamiltonian for the modified Raychaudhuri equation (3.1). However, it is not in the form $H_g + H_m$. It is vanishing, i.e., $C(x_1, x_2) \approx 0$ yields the physical solutions. These solutions are restricted to those with energy density $\rho \leq 4\rho_c$.

In contrast to the expression in classical theory, $C(x_1, x_2)$ is not linear in $H_m$. To write equation (4.4) in the form linear in matter Hamiltonian, we solve for the roots of $H_m/a^3$ using $C(x_1, x_2) \approx 0$, which results in the quadratic equation:

$$\xi (1 - \xi) = \frac{3}{32\pi G} \frac{H^2}{\rho_c},$$  

where $\xi$ is defined as $\xi = \rho/4\rho_c$. This quadratic equation admits following roots:

$$\xi_{\pm} = \frac{1}{2} (1 \pm \sqrt{1 - 4\alpha^2H^2}), \quad \text{with} \quad \alpha^2 = \frac{3}{32\pi G\rho_c}.$$  

Note that these roots individually do not span the whole range of energy density. For the negative root ($\xi_{-}$), energy density is in the range $0 \leq \rho \leq 2\rho_c$. The positive root ($\xi_{+}$) corresponds to the range $2\rho_c \leq \rho \leq 4\rho_c$. Both the independent roots are therefore essential to capture the complete dynamics in the phase space. In this modified-gravity scenario, the Hubble rate is bounded above with a maximum value $|H| = 1/2\alpha$ satisfied at $\xi_{+} = \xi_{-} = 1/2$. It vanishes at $\xi_{-} = 0$ and $\xi_{+} = 1$. The former value corresponds to the
regime where the energy density vanishes, and the latter where \( \rho \) takes its maximum allowed value, \( \rho = 4\rho_c \). From the modified Raychaudhuri equation (3.1), we find that the scale factor bounces at \( \xi_+ = 1 \). Unlike classical theory, the physical solutions are nonsingular.

The vanishing of \( C_{xx}^{12} \) results in the Hamiltonian constraint in the desired form

\[
H = -4\rho_c V\xi_{\pm} + H_m \approx 0,
\]

which is the analog of equation (2.14) for the quadratic repulsive modification. We thus obtain two equations for the roots \( \xi_+ \) and \( \xi_- \):

\[
- \frac{3V}{8\pi G\alpha^2} \left( 1 - \sqrt{1 - 4\alpha^2H^2} \right) + H_m \approx 0 \quad \text{for} \quad 0 \leq \rho \leq 2\rho_c \tag{3.8}
\]

and

\[
- \frac{3V}{8\pi G\alpha^2} \left( 1 + \sqrt{1 - 4\alpha^2H^2} \right) + H_m \approx 0 \quad \text{for} \quad 2\rho_c \leq \rho \leq 4\rho_c. \tag{3.9}
\]

The left-hand side of the above constraints is a constant of motion, and provide us Hamiltonians in the respective ranges of energy density. We denote the Hamiltonians corresponding to negative and positive roots as \( H^- \) and \( H^+ \), respectively.

We now proceed to express \( H^- \) and \( H^+ \) in terms of the canonical phase-space variables.

Given that the Hamiltonians \( H^+ \) and \( H^- \) are explicit functions of volume \( V \) and Hubble rate \( H \), it is convenient to choose these as the gravitational phase-space variables:

\[
x_1 = V, \quad \text{and} \quad x_2 = H, \tag{3.10}
\]

where \( x_1 \) and \( x_2 \) satisfy the Poisson bracket:

\[
\{x_1, x_2\}^\pm = \mu^\pm. \tag{3.11}
\]

Here \( \pm \) in the above Poisson bracket relation implies that the +ve and –ve roots of (3.5) are used for computation. It turns out that \( x_1 \) and \( x_2 \) are not canonically conjugate to each other. Using the Hamilton equations for \( x_1 \) and \( x_2 \),

\[
\dot{x}_1 = \mu^\pm \frac{\partial}{\partial x_2} H^\pm, \quad \dot{x}_2 = -\mu^\pm \frac{\partial}{\partial x_1} H^\pm \tag{3.12}
\]

and the modified Raychaudhuri equation (3.1), we obtain

\[
\mu^\pm = \pm 4\pi G \sqrt{1 - 4\alpha^2x_2^2}. \tag{3.13}
\]

The conjugate momentum variable to \( x_1 \) can be found using

\[
p^\pm = \int \frac{dx_2}{\mu^\pm}. \tag{3.14}
\]

Let us first consider the negative root. The conjugate momentum turns out to be

\[
p^- = \int \frac{dx_2}{\mu^-} = -\beta^{-1} \sin^{-1}(2\alpha x_2), \tag{3.15}
\]

where we have defined \( \beta = 8\pi G\alpha \). Thus, \( x_2 \) for this root is

\[
x_2 = -\frac{\sin(\beta^{-1})}{2\alpha}. \tag{3.16}
\]

Note that \( x_2 = H \) is bounded between zero and \( \pm 1/2\alpha \), with zero corresponding to the regime when \( \rho \) vanishes. In the range of its principal values, we find
\[- \frac{\pi}{2\beta} \leq p^- \leq 0 \quad \text{for} \quad H \geq 0 \quad (3.17)\]

and

\[0 \leq p^- \leq \frac{\pi}{2\beta} \quad \text{for} \quad H \leq 0. \quad (3.18)\]

Using \(p^-\), we can now rewrite the gravitational part of the Hamiltonian in (3.8) as

\[\mathcal{H}_g^- = - \frac{3V}{16\pi G\alpha^2} (1 - \cos (\beta p^-)). \quad (3.19)\]

Note that the above gravitational Hamiltonian, due to the allowed range of \(p^-\), is only valid for \(2\rho \geq p \geq 0\).

Repeating this calculation for the positive root \(\xi^+\), we obtain

\[p^+ = \int \frac{dx_2}{\mu^+} = \beta^{-1} \sin^{-1} (2\alpha x_2), \quad (3.20)\]

which yields

\[x_2 = \frac{\sin (\beta p^+)}{2\alpha}. \quad (3.21)\]

As in the case of the \(x_2\) for the Hamiltonian with the negative root, \(x_2\) lies in the range \(0 \leq |x_2| \leq 1/2\alpha\). However, unlike the previous case, \(x_2\) does not vanish at \(\rho = 0\), but at \(\rho = 4\rho_0\). The range of \(p^+\) is

\[0 \leq p^+ \leq \frac{\pi}{2\beta} \quad \text{for} \quad H \geq 0 \quad (3.22)\]

and

\[- \frac{\pi}{2\beta} \leq p^+ \leq 0 \quad \text{for} \quad H \leq 0. \quad (3.23)\]

The gravitational part of the Hamiltonian in (3.9) turns out to be

\[\mathcal{H}_g^+ = - \frac{3V}{16\pi G\alpha^2} (1 + \cos (\beta p^+)). \quad (3.24)\]

Having obtained (3.19) and (3.24), we notice that the angles \(\beta p^-\) and \(\beta p^+\) do not belong to the same range of principal values for any given sign of Hubble rate. For \(H \geq 0\), the maxima of the Hubble rate using \(\mathcal{H}_g^-\) is reached at \(\beta p^- = -\pi/2\), and using \(\mathcal{H}_g^+\) it is reached at \(\beta p^+ = \pi/2\). Similarly, for \(H \leq 0\), the Hubble rate for the negative root reaches its maximum at \(\beta p^- = \pi/2\), and for the positive root it is reached at \(\beta p^+ = -\pi/2\). Further, the zero of \(\beta p^-\) corresponds to the classical regime where the energy density vanishes, and that of \(\beta p^+\) corresponds to the regime where the effects of the repulsive effects of the modified gravity lead to the bounce of the scale factor. It is convenient to introduce a new variable \(p\), with a range \(-\pi/\beta \leq p \leq \pi/\beta\) and defined such that for \(H \geq 0\),

\[p := p^- \quad \text{for} \quad - \frac{\pi}{2\beta} \leq p \leq 0, \quad (3.25)\]

and

\[p := \frac{p^+ - \pi}{\beta} \quad \text{for} \quad - \frac{\pi}{\beta} \leq p \leq - \frac{\pi}{2\beta}. \quad (3.26)\]
Similarly for $H \leq 0$, 
\[ p := p^- \quad \text{for} \quad 0 \leq p \leq \frac{\pi}{2\beta}, \]  
(3.27)
and
\[ p := p^+ + \frac{\pi}{\beta} \quad \text{for} \quad \frac{\pi}{2\beta} \leq p \leq \frac{\pi}{\beta}. \]  
(3.28)

After expressing $H_q^-$ and $H_q^+$ in terms of $\beta p$, we can write the Hamiltonian for the entire range of $p$ as
\[ H = -\frac{3V}{16\pi G\alpha^2}(1 - \cos(\beta p)) + H_m \approx 0. \]  
(3.29)
This is the desired Hamiltonian in the form $H_q + H_m$ in terms of the canonical variables $V$ and $p$. Incidentally, the resulting Hamiltonian can be identified as the one in the effective space-time description of loop quantum cosmology, which is generally written in terms of the sine function [16, 19]:
\[ H = -\frac{3V}{16\pi G\alpha^2} \sin^2(\beta p/2) + H_m \approx 0, \]  
(3.30)
where we recall that $\alpha = (3/(32\pi G\rho_c))^{1/2}$ and $\beta = 8\pi G\alpha$. In loop quantum cosmology, $\beta$ encodes the area gap in the underlying quantum geometry that fixes the value of $\rho_c$ in the modified Raychaudhuri equation. The effective Hamiltonian in loop quantum cosmology emerges for suitable semiclassical states after the polymer quantization of gravitational phase-space variables has been performed [19]. In loop quantum cosmology, polymer quantization, which is inequivalent to Fock quantization, is tied to the use of holonomies of connection as elementary variables for quantization. These holonomies result in trigonometric terms of momentum (which is related to connection) in the effective Hamiltonian [17]. However, to obtain the Hamiltonian in equation (3.30), we did not start from any input from loop quantum cosmology. We only assumed a modified Raychaudhuri equation (3.1) that gives repulsive gravity with a $\rho^2$ correction with a positive sign and sought a canonical Hamiltonian linear in the matter Hamiltonian. Recall that in the classical case, the conjugate momentum to volume is proportional to the Hubble rate. Hence, the conjugate momentum in the present modified-gravity scenario turns out to be an inverse trigonometric function of the classical momentum to the generalized coordinate $V$. Polymerization thus emerges naturally.

The Hamiltonian (3.29) is not restricted to the case of dust as matter content but as in the case of classical cosmology is valid for a matter Hamiltonian corresponding to any other equation of state. As in the classical case, it is straightforward to repeat the analysis and find that the same Hamiltonian is reached if we consider matter with a different fixed equation of state. Finally, the modified Friedmann equation can be obtained by the vanishing Hamiltonian $H$, which is given by
\[ H^2 = \frac{8\pi G}{3}\rho\left(1 - \frac{\rho}{4\rho_c}\right). \]  
(3.31)
This is the same Friedmann equation as in loop quantum cosmology for the spatially flat FRW model, with $4\rho_c$ corresponding to the bounce density [15, 16]. The dynamics resulting from the Hamiltonian have been extensively studied in loop quantum cosmology [17]. It turns out that the effective space-time is geodesically complete and all strong curvature singularities are resolved in this modified-gravity scenario [14].
4. The Raychaudhuri equation with a quadratic attractive modification in energy density

We now consider a $\rho^2$ modification to the classical Raychaudhuri equation with a negative sign. In contrast to the modified Raychaudhuri equation considered in section 3, which leads to repulsive gravity irrespective of the equation of state once $\rho > \rho_0$, the modification considered in this section makes gravity more attractive than in the classical GR. For the case of dust as matter, our starting point is the following modified Raychaudhuri equation:

$$ \ddot{a} = -\frac{4\pi G}{3} \rho \left( 1 + \frac{\rho}{\rho_0} \right) a. \quad (4.1) $$

As in the quadratic repulsive case, the modification to the Raychaudhuri equation is supposed to arise from a modified theory of gravity without changing the number of degrees of freedom. The energy density scale $\rho_0$ is to be determined from the underlying theory.

To determine the constant of the motion, as before we start by considering $x_1 = a$ and $x_2 = \dot{a}$. In terms of these variables, the modified Raychaudhuri equation (4.1) can be written as two first-order equations:

$$ \dot{x}_1 = x_2, \quad \dot{x}_2 = -\frac{4\pi G}{3} \rho \left( 1 + \frac{\rho}{\rho_0} \right) x_1. \quad (4.2) $$

Comparing the above set with equation (2.5), we identify:

$$ A(x_1) = -\frac{4\pi G}{3} \rho \left( 1 + \frac{\rho}{\rho_0} \right) x_1, \quad \text{and} \quad B(x_2) = 1. \quad (4.3) $$

Using equation (2.6) and the relation between energy density and matter Hamiltonian, we obtain a constant of the motion:

$$ C(x_1, x_2) = \frac{x_2^2}{2} - \frac{4\pi G}{3} \frac{H_m}{a^3} \left( 1 + \frac{H_m}{4\rho_0} a^3 \right) x_1^2. \quad (4.4) $$

It is straightforward to verify that, as in the classical and quadratic repulsive modification, $C(x_1, x_2)$ serves as a Hamiltonian. However, it is not in the form $\mathcal{H}_g + \mathcal{H}_m$. To obtain a Hamiltonian in the form linear in gravitational and matter Hamiltonian, we find the roots of the quadratic equation obtained from $C(x_1, x_2) \approx 0$:

$$ \xi^2 + \xi - \frac{3}{32\pi G} \frac{H^2}{\rho_0} = 0, \quad \text{with} \quad \xi := \frac{\rho}{4\rho_0}. \quad (4.5) $$

The resulting roots are

$$ \xi_+ = \frac{1}{2} \left( 1 + \sqrt{1 + 4\alpha^2 H^2} \right) \quad \text{and} \quad \xi_- = \frac{1}{2} \left( 1 - \sqrt{1 + 4\alpha^2 H^2} \right), $$

with $\alpha^2 := \frac{3}{32\pi G \rho_0}$. \quad (4.6)

The negative root implies $\rho < 0$. Hence, this root results in violation of the weak energy condition and is not considered in the following discussion\(^4\). Unlike the case of quadratic repulsive modification to the Raychaudhuri equation, it is easily seen that the Hubble rate is

\(^4\) If we repeat the following analysis for this root, instead of a sine hyperbolic term, we obtain a cosine hyperbolic term in equation (4.10), with $p = e^{2\rho \sinh^{-1}(2\alpha H)}$.\)
not bounded in the present case. Another contrasting feature is that a single root \( \xi_c \) spans the whole range of positive energy density. Thus, we expect the canonical Hamiltonian structure to be different than in the quadratic repulsive case.

The Hamiltonian constraint \( C(x_1, x_2) \approx 0 \) results in an equation of the form (3.7), with \( \xi_c \) as the roots given above. For the positive root that is allowed by weak energy condition, we obtain

\[
\mathcal{H} = \frac{3V}{8\pi G \alpha^2} \left(1 - \sqrt{1 + 4\alpha^2 H^2}\right) + \mathcal{H}_m \approx 0. \tag{4.7}
\]

We thus obtain a Hamiltonian for the modified Raychaudhuri equation (4.1) in the form \( \mathcal{H}_c + \mathcal{H}_m \). However, the gravitational part of the Hamiltonian has yet to be expressed in terms of the canonical variables. As before, given the form of the Hamiltonian it is convenient to now choose \( x_1 = V \) and \( x_2 = H \). Computing the Hamilton equations and comparing them with the modified Raychaudhuri equation (4.1), we find

\[
\{V, H\} = \mu = -4\pi G \sqrt{1 + 4\alpha^2 H^2}. \tag{4.8}
\]

Thus, the conjugate momentum to \( V \) turns out to be

\[
p = \int \frac{dx_2}{\mu} = -\beta^{-1} \sinh^{-1}(2\alpha x_2). \tag{4.9}
\]

The Hubble rate diverges as the conjugate momentum \( p \) diverges. This behavior is very similar to the case of the classical theory discussed in section 2, and is an indication of the problem of singularities in this modified theory of gravity.

Expressing the Hamiltonian (4.7) in terms of the conjugate variables, we obtain

\[
\mathcal{H} = -\frac{3V}{8\pi G \alpha^2} \sinh^2(\beta p/2) + \mathcal{H}_m \approx 0, \tag{4.10}
\]

with \( \alpha = (3/(32\pi G \rho))^{1/2} \) and \( \beta = 8\pi G \alpha \). The above Hamiltonian results in the modified Friedmann equation:

\[
H^2 = \frac{8\pi G}{3} \rho \left(1 + \frac{\rho}{4\rho_c}\right). \tag{4.11}
\]

We can now contrast the canonical Hamiltonian (4.10) with the Hamiltonian for the quadratic repulsive case (3.30). Instead of a trigonometric function of the classical conjugate momentum to volume, the Hamiltonian in the quadratic attractive modification to the classical Raychaudhuri equation consists of a hyperbolic function. Thus, there is no polymerization. Physical solutions of this Hamiltonian are strikingly different than the one for the quadratic repulsive modification where the Hubble rate turned out to be universally bounded. In this modified-gravity scenario, the dynamical solutions are singular. The resulting phase-space structure and dynamics bears closer resemblance to the one in classical Hamiltonian cosmology. Let us see whether the above modified-gravity scenario bears some resemblance to known models. It is interesting to note that a modified Friedmann equation with a similar correction arises on the 4-D FRW brane in brane world scenarios if one ignores the contribution from the 5-D bulk black hole, and the 4-D cosmological constant vanishes [21]. In this case, \( \rho_c \) is identified with the brane tension. The covariant Raychaudhuri equation on the brane then agrees with the modified Raychaudhuri equation (4.1). Incidentally, the Hamiltonian constraint (4.10) can also be considered as originating from the Euclideanized version of (3.30) or equivalently the loop quantum cosmology Hamiltonian constraint using an imaginary value of the conjugate momentum \( p \) (or a complex Ashtekar connection).
5. The Raychaudhuri equation with a cubic repulsive modification in energy density

Let us consider the case of a repulsive modification to the classical Raychaudhuri equation with a $\rho^3$ correction. As before, the modification is assumed to not introduce any additional degrees of freedom. For dust as matter, the classical Raychaudhuri equation modifies as follows:

$$
\ddot{a} = -\frac{4\pi G}{3} \rho \left( 1 - \frac{\rho^2}{\rho_c^2} \right) a.
$$

(5.1)

Using $x_1 = a$ and $x_2 = \dot{a}$, this equation can be written as two first-order differential equations:

$$
\dot{x}_1 = x_2, \quad \dot{x}_2 = -\frac{4\pi G}{3} \rho \left( 1 - \frac{\rho^2}{\rho_c^2} \right) x_1.
$$

(5.2)

Comparing with equation (2.5), we can identify

$$
A(x_1) = -\frac{4\pi G}{3} \rho \left( 1 - \frac{\rho^2}{\rho_c^2} \right), \quad \text{and} \quad B(x_2) = 1.
$$

(5.3)

The constant of the motion using (2.6) turns out to be

$$
C(x_1, x_2) = \frac{x_2^2}{2} - \frac{4\pi G}{3} \rho \left( 1 - \frac{\rho^2}{\rho_c^2} \right) x_1^2.
$$

(5.4)

As in the case of $\rho^2$ modifications to the Raychaudhuri equation, $C(x_1, x_2)$ serves as a Hamiltonian that vanishes due to general covariance of the theory. To obtain a Hamiltonian in the form $H = H_m$, we need to solve the cubic equation obtained from $C(x_1, x_2) \approx 0$, which is

$$
\zeta^3 - \zeta + \sigma^2 H^2 = 0.
$$

(5.5)

Here we have defined $\zeta = \rho / \sqrt[3]{\rho_c}$ and $\sigma^2 = 3/(8\sqrt[3]{\pi G\rho_c})$. From this equation we see that the maxima of $H^2$ occurs at $\zeta^2 = 1/3$. For $\rho \geq 0$, the maximum value of $|H|$ is obtained at $\zeta = 1/\sqrt{3}$, and this value is

$$
H^2_{\text{max}} = \frac{2}{3\sqrt{3} \sigma^2}.
$$

(5.6)

Thus, as in the quadratic repulsive modifications studied in section 3, the cubic repulsive modification results in a bounded Hubble rate. Insight from studies in loop quantum cosmology where the Hubble rate is also universally bounded [14, 20], whose Hamiltonian can be identified with the quadratic repulsive case, suggests that the dynamics are singularity free [22]. The Hubble rate vanishes in the high curvature regime at $\rho = \sqrt[3]{\rho_c}$, where the scale factor of the Universe bounces and avoids the big bang singularity.

Equation (6.5) has three real roots, which are

$$
\zeta_i = \frac{2}{\sqrt{3}} \cos \left( \frac{1}{3} \cos^{-1} \left( -\frac{3\sqrt{3} \sigma^2 H^2}{2} \right) \right).
$$

(5.7)
\[ \zeta_2 = \frac{2}{\sqrt{3}} \cos \left( \frac{1}{3} \cos^{-1} \left( -\frac{3\sqrt{3}}{2} \sigma^2 H^2 + \frac{2\pi}{3} \right) \right), \]  
\tag{5.8} \]

and
\[ \zeta_3 = \frac{2}{\sqrt{3}} \cos \left( \frac{1}{3} \cos^{-1} \left( -\frac{3\sqrt{3}}{2} \sigma^2 H^2 + \frac{4\pi}{3} \right) \right), \]  
\tag{5.9} \]

These roots allow us to write a Hamiltonian constraint starting from \( C \approx 0 \):
\[ H = -\sqrt{7} \zeta_i \rho_i V + H_m \approx 0, \quad (i = 1, 2, 3), \]  
\tag{5.10} \]

which is the analog of equation (2.14) in the classical case and equation (3.7) in the quadratic modifications to the Raychaudhuri equation.

It is instructive to take the limit \( \alpha H \rightarrow 0 \) to gain some insights on these roots. In this limit, the roots can be expanded as
\[ \zeta_1 \approx 1 - \frac{\sigma^2 H^2}{2} - \frac{3\sigma^4 H^4}{8} - \frac{\sigma^6 H^6}{2} - \frac{105\sigma^8 H^8}{128} + O(\sigma^{10} H^4), \]  
\tag{5.11} \]

\[ \zeta_2 \approx -1 - \frac{\sigma^2 H^2}{2} + \frac{3\sigma^4 H^4}{8} - \frac{\sigma^6 H^6}{2} + \frac{105\sigma^8 H^8}{128} + O(\sigma^{10} H^4), \]  
\tag{5.12} \]

and
\[ \zeta_3 \approx \sigma^2 H^2 + \sigma^6 H^6 + 3\sigma^{10} H^{10} + O(\sigma^{13} H^{13}). \]  
\tag{5.13} \]

Note that in the absence of \( \rho^3 \rho^3 \) modification, i.e., in the classical theory, \( \zeta = \sigma^2 H^2 \). Thus, the root \( \zeta_1 \) captures the classical limit in the regime where the Hubble rate is vanishingly small. The root \( \zeta_1 \) captures the bounce regime where the Hubble rate vanishes. On the other hand, the root \( \zeta_2 \) is always negative, and results in violation of the weak energy condition. In the following, we will only consider roots \( \zeta_1 \) and \( \zeta_3 \) as it is only for these that the energy density is positive. The \( \zeta_1 \) root provides dynamics in the range of \( \rho = \sqrt{7} \rho_1 \), the maximum value of energy density, until \( \rho = \sqrt{7} \rho_1 / \sqrt{3} \), where the Hubble rate attains its maximum value. The \( \zeta_3 \) root covers dynamics in the lower range of energy density, from \( \rho = \sqrt{7} \rho_1 / \sqrt{3} \) until vanishing energy density.

We first consider the Hamiltonian corresponding to the \( \zeta_1 \) root (equation (5.7)). The vanishing of \( C(x_1, x_2) \) yields
\[ \mathcal{H}(x_1, x_2) = -\frac{3x_1 \zeta_1}{8\pi G\sigma^2} + H_m \approx 0, \]  
\tag{5.14} \]

where we have chosen \( x_1 = V \) and \( x_2 = H \), satisfying \( \{x_1, x_2\} = \mu_{\zeta_1} \). The Hamilton equation for \( x_1 \) is
\[ \dot{x}_1 = \mu_{\zeta_1} \frac{\partial \mathcal{H}}{\partial x_2} = \frac{3x_0 x_2}{4\pi G \mu_{\zeta_1}} \sin \left( \frac{1}{3} \cos^{-1} \left( -\chi^2 \right) \right), \]  
\tag{5.15} \]

where \( \chi^2 \) is defined as \( \chi^2 = \frac{1}{2} \sqrt{1 - \frac{\chi^2}{\mu_{\zeta_1}}} \). Using \( V = 3 VH \), we find that
\[ \mu_{\zeta_1} = 4\pi G \frac{\sqrt{1 - \chi^2}}{\sin \left( \frac{1}{3} \cos^{-1} \left( -\chi^2 \right) \right)}. \]  
\tag{5.16} \]
Thus, $x_1$ and $x_2$ are not conjugate variables. The conjugate momentum to $x_1$ can be found by using

$$p_{\zeta_1} = \int \frac{\mathcal{H}}{\mu_{\zeta_1}}.$$ 

Note that $\mu_{\zeta_1}$ is a bounded function, with its maximum value equal to $8\pi G$ attained when $\sigma H \to 0$, and the minimum value equal to zero is reached when $|\sigma H| = \sqrt{2/3}$ . The integral yields an intricate relation between the conjugate momentum and the Hubble rate:

$$p_{\zeta_1} = \frac{1}{4\pi G} \frac{3^{1/4}}{\sqrt{2\sigma}} \left[ \frac{\chi^4}{1 + e^{2\chi}\cos(-\chi^2)} e^{-\chi\cos(-\chi^2)} \right]$$

$$\times \left[ -\frac{2\chi^2}{e\chi^3}\cos(-\chi^2) \right] 2F_1 \left( \frac{5}{12}, \frac{1}{2}; \frac{17}{12}; e^{-2\chi\cos(-\chi^2)} \right)$$

$$+ 5 \frac{2\pi G}{\chi^2} \frac{\chi^4}{1 + e^{2\chi}\cos(-\chi^2)} e^{-\chi\cos(-\chi^2)} \right].$$

(5.17)

where we recall that $\sigma = (3/(8\sqrt{3}\pi G\mu))^{1/2}$. The conjugate momentum is a hypergeometric function of the inverse trigonometric function of the classical conjugate momentum $H$. Taking the allowed limits of the Hubble rate, it can be found that it is real and finite.

We now consider the root $\zeta_3$ (equation (5.9)). In this case, the Hamiltonian constraint in terms of $x_1 = V$ and $x_2 = H$ is

$$\mathcal{H}(x_1, x_2) = -\frac{3x_1\zeta_3}{8\pi G\sigma^2} + \mathcal{H}_m \approx 0.$$  

(5.18)

Using the Hamilton equations, we find that $\mu_{\zeta_3}$ is given by

$$\mu_{\zeta_3} = 4\pi G \frac{\sqrt{1 - \chi^4}}{\cos\left(\frac{\pi}{6} - \frac{1}{3}\cos^{-1}(-\chi^2)\right)},$$

(5.19)

where $\chi^2 = \frac{3\sqrt{3} \sigma H^2}{2}$. We find that $\mu_{\zeta_3}$ is a bounded function with a maximum and minimum values obtained at $\sigma H = 0$ and $|\sigma H| = \sqrt{2/3}$, respectively. The conjugate momentum to $x_1$ turns out to be

$$p_{\zeta_3} = -\frac{1}{4\pi G} \frac{3^{1/4}}{\sqrt{2\sigma}} \left[ (-1)^{1/3} \chi^4 \left[ 1 + e^{2\chi}\cos(-\chi^2) \right] e^{-\chi\cos(-\chi^2)} \right]$$

$$\times \left[ \frac{2\chi^2}{e\chi^3}\cos(-\chi^2) \right] 2F_1 \left( \frac{5}{12}, \frac{1}{2}; \frac{17}{12}; e^{-2\chi\cos(-\chi^2)} \right)$$

$$+ 5 (-1)^{1/3} \frac{2\pi G}{\chi^2} \frac{\chi^4}{1 + e^{2\chi}\cos(-\chi^2)} e^{-\chi\cos(-\chi^2)} \right].$$

(5.20)

which like $p_{\zeta_1}$ is real and finite in the allowed range of Hubble rate.

The conjugate momenta $p_{\zeta_2}$ and $p_{\zeta_3}$ capture the dynamics in the phase space for $\sqrt{\frac{7}{4}} \rho_5 \geq \rho \geq \sqrt{\frac{7}{4}} \rho_5/\sqrt{3}$ and $\sqrt{\frac{7}{4}} \rho_5/\sqrt{3} \geq \rho \geq 0$, respectively. Unfortunately, their complicated form forbids us to express the roots $\zeta_2$ (equation (5.7)) and $\zeta_3$ (equation (5.9)) in terms of $p_{\zeta_2}$ and $p_{\zeta_3}$. Nevertheless, valuable information is gained by plotting $p_{\zeta_2}$ and $p_{\zeta_3}$ versus the roots $\zeta_2$ and $\zeta_3$, and the Hubble rate. These plots are shown in figure 1, which depict periodic relationships between the conjugate momenta and the corresponding roots, and the Hubble
rate. Their periodic variations turn out to be very similar to the one for the quadratic repulsive case studied in section 3. To understand this in detail and to compare with the quadratic repulsive case, let us denote the conjugate momenta \( p_{\zeta_1} \) and \( p_{\zeta_3} \) as \( p \), where it is understood that contributions to \( p \) come from the former momenta in their respective ranges. It turns out that the variations are periodic in \( p \). The period of an oscillation for the entire allowed range of the Hubble rate is approximately \( h = \frac{p}{2.62} \), where \( h = \frac{4\pi G}{3} \) and \( ((\sigma))^2 = \frac{G}{387} \). Note that in the quadratic repulsive case, this period is \( p_b = \frac{p}{2} \), with \( b \) and \( ((\alpha))^2 = \frac{G}{33} \).

Let us see the way the critical energy density in the quadratic and cubic repulsive cases is related to the period of oscillation. In the quadratic repulsive case, the value of the conjugate momentum \( p \) where \( \alpha H \) becomes maximum lies exactly in the middle of the half-period of oscillation. At this value of \( p \), which is \( \frac{p}{2} \), the energy density reaches \( 2\rho_1 \). The maximum value of energy density, \( \rho = 4\rho_1 \), is reached at \( p = \pm\pi/\beta \). The relationship between the period \( P \) and the \( \rho_1 \) in the quadratic repulsive case turns out to be

\[
P = \frac{2\pi}{\beta} \approx 1.45 \left( \frac{\rho_1}{G} \right)^{1/2}. \tag{5.21}
\]

In contrast, in the cubic repulsive case the value of \( p \) at which \( |\sigma H| \) attains its maximum does not lie exactly in the middle of the half-period, but at a little less value. At this value, which is approximately \( p = \pi/(6\eta) \), the energy density becomes \( \rho = \sqrt{3/\beta} \rho_1 \). The maximum value of energy density, \( \rho = \sqrt{3} \rho_1 \), is reached at \( p = \pm 1.31/\eta \). This is evident in the plot on the left side of figure 1. In the cubic repulsive case, the period of oscillation \( P \) is related to critical density \( \rho_\xi \) as

\[
P = \frac{2.62}{\eta} \approx 0.98 \left( \frac{\rho_\xi}{G} \right)^{1/2}. \tag{5.22}
\]
Hence the period of oscillation in the quadratic repulsive case is approximately 1.5 times that in the cubic repulsive case.

In figure 1, we also see the periodic behavior of the roots \( \zeta \) with respect to the conjugate momenta for two cycles ranging in all the allowed values of the Hubble rate. Again, the behavior is quite similar to that of the quadratic repulsive case, except with a shorter period, which we calculated above. In the quadratic repulsive case, two such cycles cover \( p = 4\pi/\beta \). Thus we find that quadratic repulsive and cubic repulsive modifications result in qualitatively similar, but quantitatively distinct periodic behaviors of the corresponding roots in terms of conjugate momentum. Another way to look at these similarities is via the expansion of \( \zeta \)'s around the bounce point and the classical regimes considered in equations (5.11) and (5.13). If we consider the expansion of corresponding roots (\( \xi \)'s) in the quadratic repulsive case, then we find that they have very similar expansions in terms of the Hubble rates in the bounce and classical regimes.

The Hamiltonians (5.14) and (5.18) that capture the evolution in different ranges of energy density give us the desired Hamiltonian structure with the Hamiltonian as a linear combination of gravitational and matter parts. As in the earlier cases, we note that although we started with dust as matter, the final Hamiltonian is valid for a general matter Hamiltonian. We notice that as in the case of repulsive quadratic modification, \( \rho^3 \) modification to the classical Raychaudhuri equation yields a canonical phase-space structure that is disjoint in conjugate momenta for the entire allowed range of energy density. The conjugate momenta again involves inverse trigonometric functions of the Hubble rate, albeit relatively complicated ones. These are hypergeometric functions of the inverse trigonometric functions, which as discussed above and depicted in figure 1, share very similar periodic features with the quadratic repulsive case. The periodic behavior of the roots \( \zeta_{(1,3)} \) with respect to the conjugate momenta implies that as in the quadratic repulsive case, the Hamiltonian is also periodic in the conjugate momentum. Due to the existence of periodicity of the Hamiltonian in the conjugate momentum in a more general form than the simple trigonometric function in the quadratic repulsive case, which is linked to polymerized phase space, we can view the resulting phase space as a ‘generalized polymerized’ form.

Finally, the modified Friedmann equation emerging from the vanishing of the Hamiltonian in this modified-gravity scenario is

\[
H^2 = \frac{8\pi G}{3} \left( 1 - \frac{\rho^2}{7\rho_c^2} \right)
\]

Unlike the quadratic repulsive modification, phenomenological implications resulting from this and the modified Raychaudhuri equation (5.1) of this new nonsingular Hamiltonian cosmology have yet to be studied. We expect many features to be qualitatively similar to the quadratic repulsive case, but quantitative details and predictions will be different.

6. The Raychaudhuri equation with a cubic attractive modification in energy density

The cubic repulsive modification to the classical Raychaudhuri equation causes gravity to be more attractive than any of the previous cases for modified-gravity scenarios studied so far in this manuscript. The modified Raychaudhuri equation for dust as matter is assumed to be of the following form:
\[ \ddot{a} = -\frac{4\pi G}{3} \rho \left( 1 + \frac{\rho^2}{\rho_c^2} \right) a. \] 

(6.1)

As in all other considered modifications in our analysis, general covariance is assumed to remain unchanged and no new degrees of freedom are added in this modified-gravity scenario.

Starting with \( x_1 = a \) and \( x_2 = \dot{a} \), we can rewrite equation (6.1) as two first-order equations:

\[ \dot{x}_1 = x_2, \quad \dot{x}_2 = -\frac{4\pi G}{3} \rho \left( 1 + \frac{\rho^2}{\rho_c^2} \right) x_1. \]

(6.2)

This set is equivalent to (2.5) for

\[ A(x_1) = -\frac{4\pi G}{3} \rho \left( 1 + \frac{\rho^2}{\rho_c^2} \right) x_1 \quad \text{and} \quad B(x_2) = 1. \]

(6.3)

Using \( A(x_1) \) and \( B(x_2) \) in equation (2.6) we find the constant of motion in this modified gravity as

\[ C(x_1, x_2) = \frac{x_1^2}{2} - \frac{4\pi G}{3} \rho \left( 1 + \frac{\rho^2}{\rho_c^2} \right) x_1^2. \]

(6.4)

This constant of motion serves as a Hamiltonian yielding the Hamilton equations consistent with the modified Raychaudhuri equation (6.1) for \( x_1 \) and \( x_2 \) as conjugate variables. However, as for all other previous cases, it is not a linear combination of gravitational and matter Hamiltonians. Using our strategy of imposing \( \alpha = 0 \) to find the desired Hamiltonian we are led to the following cubic equation:

\[ \zeta^3 + \zeta - \sigma^2 H^2 = 0. \]

(6.5)

Here \( \zeta \) and \( \sigma \) are defined as in section 5, \( \zeta := \rho / \sqrt{7} \rho_c \), and \( \sigma^2 = 3/8 \sqrt{7} \pi G \rho_c \). The above equation permits only one real root that allows positive energy density. This single root \( \zeta \) is

\[ \zeta = \frac{2}{\sqrt{3}} \sinh \left( \frac{1}{3} \sinh^{-1} (\chi^2) \right). \]

(6.6)

The vanishing \( C \) yields the following Hamiltonian constraint in the form \( \mathcal{H}_s + \mathcal{H}_m \). It satisfies the Hamiltonian constraint obtained from \( C \approx 0 \) in the form

\[ \mathcal{H} = -\frac{3x_1 \zeta}{8\pi G \rho_c^2} + \mathcal{H}_m \approx 0, \]

(6.7)

where \( x_1 = V \) and \( x_2 = H \). This equation is equivalent to (5.10) for \( \zeta \) identified with \( \zeta_s \). To find the conjugate phase-space variables, we analyze the Hamilton equations. The Hamilton equation for \( x_1 \) is

\[ \dot{x}_1 = \mu \frac{\partial \mathcal{H}}{\partial x_2} = -\frac{3x_1 x_2}{4\pi G \rho_c} \frac{\cosh \left( \frac{1}{3} \sinh^{-1} (\chi^2) \right)}{\sqrt{1 + \chi^2}}. \]

(6.8)
where as before $\chi^2 = \frac{3\sqrt{3}\sigma^2 H^2}{4}$. For consistency of Hamiltonian evolution we need
\[
\mu = -4\pi G \frac{\sqrt{1 + \chi^4}}{\cosh \left( \frac{1}{2} \sinh^{-1}(\chi^2) \right)}.
\] (6.9)
The conjugate variable to $x_1$ can be found by the following integration:
\[
p = \int \frac{dH}{\mu},
\] (6.10)
which yields
\[
p = -\frac{1}{4\pi G} \frac{3^{1/4}}{5\sqrt{2}\sigma} \chi^{-1} e^{-\frac{1}{3} \sinh^{-1} \chi} \sqrt{1 - e^{2 \sinh^{-1} \chi}} \left[ 5 \, _2F_1 \left( \frac{1}{12}, \frac{1}{2}; \frac{13}{12}; e^{2 \sinh^{-1} \chi} \right) \right. \\
+ \left. e^{\frac{2}{3} \sinh^{-1} \chi} \, _2F_1 \left( \frac{5}{12}, \frac{1}{2}; \frac{17}{12}; e^{2 \sinh^{-1} \chi} \right) \right].
\] (6.11)
with $\sigma = (3/(8 \sqrt{7} \pi G \rho))^1/2$. Let us compare the resulting canonical phase-space structure with the previous cases. As in quadratic attractive modification, the conjugate momentum involves the inverse hyperbolic functions of the Hubble rate, and there is no polymerization. But as in the cubic repulsive case, we obtain hypergeometric functions that make expressing $\zeta$ in terms of $p$ complicated. In another similarity to the quadratic attractive case, there is only one root, $\zeta$, which covers the whole positive range of energy density. The canonical phase-space structure is hence quite different from the repulsive modified-gravity cases where there are two physical roots. It is straightforward to see that the Hubble rate in this case is unbounded, which is also transparent from the modified Friedmann equation following from the vanishing of Hamiltonian:
\[
H^2 = \frac{8\pi G}{3} \rho \left( 1 + \frac{\rho^2}{\rho^2_c} \right).
\] (6.12)
This equation, as is the Hamiltonian, is valid for matter with any equation of state. A divergence in energy density causes the Hubble rate to diverge and the resulting space-time is geodesically incomplete. The approach to singularity occurs faster than in the classical and quadratic attractive cases.

### 7. Discussion

Let us begin by summarizing the main goals and steps of our procedure. We have provided a systematic method to determine the canonical Hamiltonian directly from the equations of motion in spatially flat isotropic and homogeneous cosmological models in modified gravity without any information about the Lagrangian. We asked what type of canonical structures of the cosmological models in modified theories produce the total Hamiltonian as a linear combination of gravity and matter Hamiltonians, $\mathcal{H}_g + \mathcal{H}_m$, without violation of the conservation law of matter energy and general covariance. We considered modifications to the Raychaudhuri equation involving quadratic and cubic terms of energy density that make gravity repulsive above a curvature scale for matter satisfying a strong energy condition, or more attractive than in GR. Modifications are assumed to be such that no new degrees of freedom are added. Using these conditions we obtain the Hamiltonian and canonical phase-space structure for all the considered modified cosmological theories. In the quadratic
repulsive modification, our approach can be viewed as a reverse procedure to obtain the effective canonical Hamiltonian in loop quantum cosmology. For other modifications, the canonical Hamiltonian structures found here are new and have been investigated for the first time in literature.

Our starting point is finding a constant of the motion $C$. This constant of motion serves as an intermediate Hamiltonian in our procedure. It does not have the distinction of being the desired Hamiltonian because it does not comply with our requirement that the Hamiltonian be a linear combination of gravitational and matter parts. At this point it becomes crucial to use the vanishing of the (intermediate) Hamiltonian ($C = 0$), a result of general covariance, and phase-space variables transforming as scalars under time reparameterization to obtain the desired Hamiltonian and the canonical phase-space structure. As a consequence of our three requirements—the constancy of $C$, the vanishing of $C$ which gives physical space of solutions, and, $H = H_g + H_m$—we find starting from the Raychaudhuri equation and its modifications that $H = H_m - \rho a^3$, where $\rho$ is a root of the equation $C = 0$. Once the Hamiltonian is obtained in this form, we derive the canonical phase-space structure. This is the main summary of our procedure. Note that our approach is based on the relation between the Hamiltonian and the existence of constants of motion, which can be $N^2 - 1$ at most for $N$ degrees of freedom. But all problems always have $2N$ constants of motion, the $2N$ initial conditions. This is taken care of by assuming that at most $2N - 1$ constants of motion have to be time independent and isolating, i.e., allowing for reduction of the dimensionality of the phase space.

What modifications to the Raychaudhuri equation tell us about the underlying canonical Hamiltonian structure? In the quadratic repulsive case, the modified phase space of gravity is a polymerized phase space, which is characteristic of models in loop quantum gravity. The canonical momentum turns out to be an inverse trigonometric function of the Hubble rate. The canonical Hamiltonian can be identified with the effective Hamiltonian in loop quantum cosmology if we appropriately identify $4\rho$ with the bounce density in loop quantum cosmology. The repulsive cubic modification results in a new nonsingular Hamiltonian cosmology whose gravitational phase space has a ‘generalized polymerized’ structure with momenta as hypergeometric functions of inverse trigonometric functions of the Hubble rate. Both the repulsive modifications are found to yield a bounded Hubble rate. Here it is worth noting that investigations on the resolution of strong curvature singularities in loop quantum cosmology [14] show that these are generically resolved. This conclusion immediately extends to the quadratic repulsive case, and similar conclusions follow for the cubic repulsive case [22]. In contrast, attractive modifications result in a non-polymerized gravitational phase space. In both of the cases considered here, the Hubble rate is not bounded and singularities persist for matter that does not violate the weak energy condition. The quadratic attractive modification results in modified gravity that has similarities with the brane world scenarios [21].

Let us discuss some of the directions in which our procedure can be extended and generalized. We have focused in this manuscript on the Hamiltonians of modified-gravity scenarios. The question concerning the corresponding covariant action for these canonical Hamiltonians remains to be addressed. It was shown earlier that an effective dynamical equation of loop quantum cosmology can be obtained from a covariant generalized Palatini action $f(R)$, where $f(R)$ is an infinite series in the curvature scalar of the connection $R$, without metric-connection compatibility enforced [23]. It is interesting to understand this result in light of the inverse procedure provided in this work for the repulsive modified-gravity cases. The action obtained in [23] can be considered as an action for the quadratic
repulsive case in our analysis. However, we need to understand the relationship between the canonical Hamiltonian structure and this action in more detail. Whether or not such an action exists for the cubic repulsive case is an open question. These exercises promise to give valuable insight on modified-gravity scenarios where degrees of freedom do not change, as considered in our analysis, and on investigations starting from higher-order actions. Similarly, it is interesting to generalize our procedure to include nonminimally coupled matter and modifications allowing change in the degrees of freedom.

Understanding the uniqueness of the Hamiltonians obtained in this paper is an interesting avenue to explore. In particular, an important question is: Do independent and very different procedures of obtaining the Hamiltonians from the modified Raychaudhuri equations agree? The answer seems to be yes. An independent method based on our work here has its roots in the study of nonlinear dynamical systems (with variable coefficients), which has received attention for well over two centuries. In this context, Nucci and Leach recently resurrected an old method of Jacobi to derive the Lagrangian description of a second-order dynamical system, or even a system of such ordinary differential equations [24]. This direction was also explored in earlier works by Rao [25] and Whittaker [26]. It is interesting to use this technique that connects the Jacobi’s last multiplier method with the Lagrangian formulation of differential equations and determines the Lagrangian of the modified cosmological equations as considered in this work. Using the standard Legendre transformation we deduce the corresponding Hamiltonian once the Lagrangian is found. Following this independent procedure, going back to Jacobi for the modified Raychaudhuri equations studied in this manuscript, the Hamiltonians turn out to be of the same form as obtained in our analysis [27].

In our ongoing work, this analysis is extended to variants of the modified cosmological models studied here, and the precise nature of interrelation between the Hamiltonian deduced from our procedure and the Lagrangian function obtained using Jacobi’s Last Multiplier method is established. Results from our ongoing analysis show that very distinct methods lead to the same Hamiltonians for the modified-gravity scenarios.

It should be noted that starting from the Raychaudhuri equation is not fundamental to finding the Hamiltonians in our procedure. Instead, one can use the Friedmann equation and its modifications to obtain the canonical Hamiltonian structure. One can start with a constant of the motion, \( C = H_m - \rho a^3 \), which follows independently from conservation of the matter energy. If one assumes that \( \rho \) is a solution of the Friedmann equation of the classical or modified-gravity scenario, \( C \) has the distinction of being the desired Hamiltonian of the model, satisfying our requirements of \( H \approx 0 \) and \( H = H_m + H_g \). It only remains to identify the canonical gravitational phase-space variables. This can be done as shown in sections 2–6 for classical and modified-gravity scenarios. This procedure will be used in other cosmological models in an upcoming work [27].

It is interesting to compare our approach with the historic problem of finding the force law of gravity in Newtonian mechanics. Given a potential, one can always determine the trajectory it leads to. Motion under the Newtonian potential and the harmonic oscillator potential has many extraordinary properties. They are regular problems in which all bounded planar orbits are closed, whereas it is known that most potentials do not even lead to closed trajectories. In a converse sense, the mentioned atypical properties of the motion is the key to understanding the dynamical behavior of Hamiltonian systems. The Kepler problem and the isotropic harmonic oscillator have the only radial potentials in which all finite orbits are in plane and closed in agreement with the well-known Bertrand’s theorem. In a similar way, precise astronomical observations can provide valuable lessons to understand the Hamiltonian structure of the modified-gravity scenarios describing our Universe at large space-time curvature. We note that ongoing work by various groups promises that the modified

Class. Quantum Grav. 33 (2016) 125001 P Singh and S K Soni
Raychaudhuri equation for the quadratic repulsive case can be indirectly tested using cosmic microwave background (CMB) observations in the near future by analyzing the cosmological perturbations in loop quantum cosmology [17]. Similarly, various works in brane world scenarios, which yield dynamical equations bearing similar to the quadratic attractive case, have constrained parameters with supernova and CMB experiments (see, e.g., [21, 28]). It can be hoped that future astronomical experiments might constrain the modification to Raychaudhuri equation and lead us to the Hamiltonian for the modified gravity describing our Universe at very large curvature scales. This is because our simple requirements prove so restrictive that they enable us to clinch the structure of the canonical gravitational Hamiltonian directly from the properties of the gravity encoded in the dynamical equations.

What is surprising is that just by reversing the canonical principle we can shed powerful light on the connection between gravitational phase space of the underlying theory and the repulsive character of the modified gravity above a critical scale. Our findings reveal connections between our modified-gravity scenarios where degrees of freedom do not change and the structure of the gravitational phase space: No repulsive gravity? No polymerization!
