Quantum dynamics and transport in a double well system

Itamar Sela and Doron Cohen

The simplest one-dimensional model for the studying of non-trivial geometrical effects is a ring shaped device which is formed by joining two arms. We explore the possibility to model such a system as a two level system (TLS). Of particular interest is the analysis of quantum stirring, where it is not evident that the topology is properly reflected within the framework of the TLS modeling. On the technical side we provide a practical “neighboring level” approximation for the analysis of such quantum devices, which remains valid even if the TLS modeling does not apply.

I. INTRODUCTION

In this paper we explore the possibility to model a ring shaped device (Fig.1(a)) as a two level system (TLS) (Fig.1(b)). We shall see that both technical and conceptual difficulties are involved. The model Hamiltonian is

$$\mathcal{H} = \frac{1}{2m} \dot{\mathbf{p}}^2 + V_A(\mathbf{x} - x_A) + V_B(\mathbf{x} - x_B)$$

with periodic boundary conditions over \(x \in [-L/2, L/2]\) so as to have a ring geometry, as illustrated in Fig.1(a). \(V_A\) and \(V_B\) represent high barriers, such that the ring is composed of two weakly coupled arms. We assume that we have control over some geometrical parameters of the model and in particular over the heights \(X_A\) and \(X_B\) of both barriers. Our main interest is in the current that flows in the system. The current through an arbitrary point \(x_0\) is obtained as the expectation value of the operator

$$\mathcal{I} = \frac{1}{2m} (\dot{\mathbf{p}} \delta(\mathbf{x} - x_0) + \delta(\mathbf{x} - x_0) \dot{\mathbf{p}})$$

Having defined the system and its observables we can consider various dynamical scenarios such as coherent Bloch oscillations between the two arms. Then we can ask whether a TLS modeling is meaningful. Of particular interest for us is the analysis of quantum stirring [3]: this means to induce a circulating current by periodic modulation of the potential.

We note that transport due to periodic modulations of the potential [2] has been studied mainly in the context of quantum pumping [4,5], where the current is induced between reservoirs. The notion of quantum stirring relates to closed geometry, where the emerging physical picture is significantly different [6,7].

The quantum stirring problem highlights an obvious topological subtlety: one wonders whether the non trivial topology of the ring is properly reflected in the effective TLS model.

On the technical side we define the unperturbed Hamiltonian \(\mathcal{H}_0\) as the \(X_A = X_B = \infty\) limit. In this limit the two arms are disconnected from each other, and the diagonalization gives a set of eigen-energies \(E_i\) such that each eigenstate belongs to only one of the two arms. Then we make either \(X_A\) or \(X_B\) or both finite, and we ask what is the perturbation matrix \(W_{ij}\) in the reduced Hamiltonian

$$\mathcal{H}_{ij} = \begin{pmatrix} E_1 & 0 \\ 0 & E_2 \end{pmatrix} + \begin{pmatrix} W_{11} & W_{12} \\ W_{21} & W_{22} \end{pmatrix}$$

Obviously we would like to express the perturbation using the transmission coefficients of the barriers.

II. OUTLINE

In the first part of the paper (Sections III-V) we establish the building blocks. We derive expressions for the perturbation matrix \(W_{ij}\), and for the reduced current operator \(\mathcal{I}_{ij}\), and figure out how the topology is reflected in the reduced description.

In the second part of the paper (Sections VI-VII) we turn to the applications. We begin with the simplest problems: The coherent Bloch oscillations of a particle in a mirror symmetric device, and the Wigner decay of a particle from a short arm to a long arm. Then we continue with the quantum stirring problem, and show how one can derive expressions for the geometric conductance.

In the third part of the paper (Sections VIII-X) we address some non-trivial technical points that are associated with the analysis, thus exploring the limitations of the TLS modeling. We demonstrate that even if the TLS modeling does not apply, we still can use a neighboring level approximation in order to extract results for the geometric conductance.

In the Summary (Section XIII) we highlight the practical value of our findings for the purpose of design and analysis of quantum stirring devices, and we briefly relate to the experimental measurement issue.

III. THE TLS MODELING SCHEME

The unperturbed eigenstates \(\psi^i(x)\) are labeled as \(i = 1, 2\), corresponding to the two arms of the ring. The associated eigen-energies are \(E_i = k_i^2/(2m)\). We have

$$\psi^{(1)}(x) = \sqrt{\frac{2}{L_1}} \sin(k_1 x + \varphi_1) \quad \text{if } x \in \text{1st arm}$$
$$0 \quad \text{if } x \in \text{2nd arm}$$

and a similar expression for \(\psi^{(2)}(x)\), where \(L_i\) is the length of the \(i\)th arm, and \(|\varphi| < \pi/2\). Two rep-
representative eigenstates are illustrated in Fig.2. Note that the wavenumber of the particle in the ith arm is 
$k_i = (\pi/L_i) \times \text{integer}$. Our interest is in a very small energy range $E_1 \sim E_2 \sim E$, where the wavenumbers are $k_1 \sim k_2 \sim k_E$, corresponding to the velocity
$v_E = (2E/m)^{1/2}$. We would like to ignore all the other levels. Later we discuss the validity conditions for this TLS modeling scheme.

Once we lower from infinity one barrier, say barrier A, the two states become coupled. In section IV we consider a delta barrier and obtain the following expression for the perturbation matrix:

$$W^A_{ij} = -\frac{v_E}{2\sqrt{L_iL_j}} \sqrt{g_A}$$  \hspace{1cm} (5)

where $g_A$ is the transmission of the barrier. For $i \neq j$ the minus sign is a convention that fixes the gauge (see Appendix A). In section IV we show that essentially the same result applies to any other type of barrier, but the $i = j$ expression for the energy shift should be somewhat generalized.

If both barriers are finite the two associated perturbation terms should be added together, and one obtains for the energy difference

$$\varepsilon = (E_1 + W^A_{11} + W^B_{11}) - (E_2 + W^A_{22} + W^B_{22})$$  \hspace{1cm} (6)

and for the coupling

$$\frac{\kappa}{2} = W^A_{12} + W^B_{12} = -\frac{v_E}{2\sqrt{L_1L_2}} (\sqrt{g_A} \neq \sqrt{g_B})$$ \hspace{1cm} (7)

The latter expression involves a relative sign $\neq$ that cannot be gauged away (see Appendix A). If we had magnetic flux penetrating through the ring we could have, instead of the $\neq$, an arbitrary phase factor.

Using the Pauli matrices we can write the TLS Hamiltonian as

$$\mathcal{H}_{ij} = \frac{\varepsilon}{2}\sigma_z + \frac{\kappa}{2}\sigma_x = \frac{\Omega}{2}\cdot\sigma$$ \hspace{1cm} (8)

Defining $\theta$ as the angle between $\Omega$ and the ”z” axis, with the convention $0 < \theta < \pi$, the eigenstates $n_0$ and $m_0$ of this Hamiltonian are:

$$|n_0\rangle = \left[ \begin{array}{c} \mp \sin (\theta/2) \\ \cos (\theta/2) \end{array} \right], \quad |m_0\rangle = \left[ \begin{array}{c} \cos (\theta/2) \\ \pm \sin (\theta/2) \end{array} \right]$$ \hspace{1cm} (9)

where the $\pm$ indicates the sign of $\kappa$. The energy difference between these eigenstates is

$$\Omega = \sqrt{\varepsilon^2 + \kappa^2}$$ \hspace{1cm} (10)

If we have a symmetric well then the effective coupling between odd and even levels vanishes ($\kappa = 0$), and then we can get a degeneracy provided we tune appropriately the energy level difference $\varepsilon$.

The TLS description is valid if $W_{12}$ is much smaller compared with the level spacing, namely

$$\text{max}\{g_A, g_B\} \ll L_2/L_1$$ \hspace{1cm} (11)

where without loss of generality we assume $L_1 > L_2$.

In section V we are going to derive expressions for the current $I^A$ through barrier A, as defined by Eq. (4) with $x_0 = x_A$. One observes that the matrix elements of this operator in the “standard basis” of Eq. (3) vanish, because the unperturbed wavefunctions are zero at the barriers. The more careful treatment reveals that the reduced operator that gives the net current from the first arm to the second arm is

$$I_{ij} = \frac{k}{2}\sigma_y$$ \hspace{1cm} (12)

and it turns out that $I^A_{ij} = \lambda_A I_{ij}$, and $I^B_{ij} = \lambda_B I_{ij}$, where the splitting ratio is defined as

$$\lambda_A = \frac{W^A_{12}}{W^A_{12} + W^B_{12}} = \frac{\sqrt{g_A}}{\sqrt{g_A} \pm \sqrt{g_B}}$$ \hspace{1cm} (13)

with a similar definition for $\lambda_B$. We have $\lambda_A + \lambda_B = 1$, but contrary to the naive point of view $0 < \lambda_A < 1$ is not implied. Rather, if the two states have opposite parity, then one $\lambda$ is larger than 100%, while the other $\lambda$ is negative. We shall see later in Section XIII that the physical interpretation of the “splitting ratio” requires recognition in the existence of induced circulating current in the system. Thus the multiple path topology of the system is reflected in the TLS modeling via $\lambda$.

IV. THE EXPRESSION FOR $W_{ij}$ FOR A DELTA BARRIER

Let us assume that barrier B is infinitely high, while barrier A is modeled as a delta function. In other words: we consider the simplest possibility of having an infinite well $[-L/2 < x < (L/2)]$ which is divided at $x = x_A$ by a delta function:

$$V_A(x-x_A) = X_A \delta(x-x_A)$$ \hspace{1cm} (14)

The total perturbation is obtained from a sequence of infinitesimal variations of the barrier height

$$\mathcal{H}(X_A) = \mathcal{H}(\infty) - \int_{X_A}^{\infty} \frac{\partial \mathcal{H}}{\partial X} \, dX$$ \hspace{1cm} (15)

$$\equiv \mathcal{H}(\infty) + W^A$$ \hspace{1cm} (16)

For any value of $X$ the Hilbert space of the system is spanned by a set of (real) eigenfunction labeled by $n$. The matrix elements for an infinitesimal variation of the barrier height is

$$\left(\frac{\partial \mathcal{H}}{\partial X}\right)_{nm} = \psi^{(n)}(x_A) \psi^{(m)}(x_A)$$ \hspace{1cm} (17)

Using the matching conditions for a delta potential at $x = x_A$ we can express the wave function by its derivative:

$$\psi^{(n)}(x_A) = \frac{1}{2mX_A} \left[ \partial \psi^{(n)}(x_A+0) - \partial \psi^{(n)}(x_A-0) \right]$$ \hspace{1cm} (18)
A more elegant way of writing this relation is
\[ \psi^{(n)}(x_A) = \frac{1}{2mX_A} \sum_{a=1,2} \partial_a \psi^{(n)}(x_A) \] (19)

where \( \partial_a \) is defined as the \textit{radial} derivative in the direction of the \( a \)th arms that stretch out of the junction at \( x = x_A \). Defining the total radial derivative as \( \partial = \partial_1 + \partial_2 \) we get
\[ \left( \frac{\partial H}{\partial X} \right)_{nm} = \frac{1}{(2mX_A)^2} \partial \psi^{(n)}(x_A) \partial \psi^{(m)}(x_A) \] (20)

For a large barrier with small transmission
\[ g_A \approx \left( \frac{v_E}{X_A} \right)^2 \ll 1 \] (21)

the \( n \)th and \( m \)th states remain similar to some unperturbed \( i \)th and \( j \)th states. Accordingly, upon integration we get from Eq.(15) the result
\[ W_{ij}^A = -\frac{1}{4m^2X_A} \left[ \partial \psi^{(i)}(x_A) \right] \left[ \partial \psi^{(j)}(x_A) \right] \] (22)

Note that in the last equation the contribution to the total derivative \( \partial \) comes from one term only, because each unperturbed wavefunction \( \psi^{(i)}(x) \) is non-zero only in one box. Using Eq.(21) we get Eq.(3).

V. THE EXPRESSION FOR \( W_{ij}^A \) FOR A GENERAL BARRIER

It is possible to deduce an expression for \( W_{ij}^A \) without assuming a specific form of potential barrier. For the purpose of this calculation we describe the barrier at \( x = x_A \) by a general scattering matrix
\[ S = e^{i\gamma} \left( \begin{array}{cc} i\sqrt{1 - g}) e^{i\alpha} & -\sqrt{g}) e^{-i\alpha} \\ -\sqrt{g}) e^{i\alpha} & i\sqrt{1 - g}) e^{-i\alpha} \end{array} \right) \] (23)

Regarding the barrier as a \textit{junction} it can be embedded either in a closed ring geometry with the two arms attached, or in an open one-dimensional geometry with two infinite leads attached. In both cases the differential representation of \( W \) should be the same, because \( W \) is local in space. In other words \( W_{ij}^A \) should come out the same for the wavefunctions \( \psi^{(i)}(x) \) and \( \psi^{(j)}(x) \) of the ring, if in the vicinity of \( x = x_A \) they are identical with \( \Psi^{(i)}(x) \) and \( \Psi^{(j)}(x) \) of the scattering geometry.

In the scattering geometry it is conventional to label the two leads by \( a = 1, 2 \) and to define a radial coordinate \( r = |x - x_A| \). The flux normalized scattering states of the junction (assuming outgoing waves) are \( \Psi^{(i+)} \). By definition we have
\[ \Psi^{(1+)} = \begin{cases} \frac{1}{\sqrt{v_E}}[e^{-ikEr} - S_{11} e^{ikEr}] & \text{if } r \in 1 \text{st lead} \\ \frac{1}{\sqrt{v_E}}[-S_{21} e^{ikEr}] & \text{if } r \in 2 \text{nd lead} \end{cases} \] (24)

A similar expression holds for \( \Psi^{(2+)} \). If the leads are not coupled, the scattering matrix becomes \( S_0 \) with \( g = 0 \). In the vicinity of \( x = x_A \) the unperturbed scattering states coincide with those of Eq.(4) up to normalization. Namely, in the vicinity of \( x = x_A \) we have the relation
\[ \Psi^{(i)}(x) = -i \left( \frac{2L_i}{v_E} \right)^{1/2} e^{i\varphi_i} \psi^{(i)}(x) \] (25)

where
\[ \varphi_i = \frac{1}{2} \left( \gamma_0 + \frac{\pi}{2} \pm \alpha_0 \right) \] (26)

with \( + \) sign for \( i = 1, 2 \) respectively.

The relation between the scattering matrix and the perturbation matrix \( W \) can be deduced via the \( T \) matrix formalism. The \( S \) matrix is related to the \( T \) matrix through \( S = (1 - iT)S_0 \), or more explicitly
\[ [SS^{-1}]_{ij} = \delta_{ij} - i(\Psi^{(i)}|T|\Psi^{(j)}) \] (27)

In leading order \( T \) equals \( W \) so we have
\[ (\Psi^{(i)}|W|\Psi^{(j)}) \approx i(S - S_0) S_0^{-1} \] (28)

where
\[ S - S_0 = e^{i\gamma_0} \left( \frac{e^{i\alpha_0}(\delta\gamma + \delta\alpha)}{\sqrt{g}} e^{-i\alpha_0} \sqrt{g} \right) \] (29)

Thus
\[ (\Psi^{(i)}|W|\Psi^{(j)}) = -(\delta\gamma + \delta\alpha) \sqrt{g} e^{i\alpha_0} \delta\gamma e^{-i\alpha_0} \] (30)

Using Eq.(25) we deduce that each element of \( (\Psi^{(i)}|W|\Psi^{(j)}) \) involves multiplication by \( v_E/(4L_iL_j)^{1/2} \), while the \( \alpha_0 \) is canceled out. This leads to Eq.(6) for the \( i \neq j \) coupling, and a generalized expression for the energy level shifts.

VI. WIGNER DECAY AND BLOCH OSCILLATIONS

If the two arms of the ring have exactly the same length \( L_1 = L_2 = L/2 \), then the coherent Bloch oscillations of a wavepacket in such a symmetric double well are characterized by the frequency
\[ \Omega_{\text{Bloch}} = 2|W_{12}| = \frac{v_E}{L_j} \left| \sqrt{g_A} + \sqrt{g_B} \right| \] (31)

If one arm of the ring \( (L_1) \) is very long, and the other arm \( (L_2) \) is short, then a particle placed initially at the short arm will decay into the quasi continuum of the long arm. The decay rate is given by the Fermi golden rule
\[ \Gamma = \frac{2\pi}{\Delta} |W_{12}|^2 \] (32)
where $\Delta = (\pi/L)v_E$ is the mean level spacing. If the arms are coupled through barrier $A$, while barrier $B$ is infinitely high, then the decay rate is

$$\Gamma = \frac{v_E}{2L_2} g_A$$

(33)

This result agrees with the well known Gamow formula: the decay rate is given by the attempt frequency multiplied by the probability to cross the barrier.

If both barriers are finite, it is important to notice that the quasi-continuum of the long arm is composed of odd and even states. The state of the short arm, which is either even or odd, is coupled to states of the same parity with a plus sign in the expression of Eq. (7) and to states of the opposite parity with a minus sign. Accordingly, the decay rate is the sum of the decay rate to states of the same parity and the decay rate to states of the opposite parity

$$\Gamma = \sum_{\pm} \frac{2\pi}{2\Delta} \left| \frac{v_E}{2\sqrt{L_1 L_2}} \left( \sqrt{g_\alpha \pm \varepsilon} \right) \right|^2$$

$$= \frac{v_E^2}{2L_2} (g_A \pm g_B)$$

(34)

where $\Delta = 2\Delta$ is the mean level spacing for states with the same parity. So despite of the parity considerations we still get the naive result that agree with Gamow formula.

**VII. QUANTUM STIRRING**

We assume that we have control over geometrical parameters of the device, such as the potential floor in each arm, the barriers heights, their location, or any other gate controlled feature of the potential landscape. With a control parameter $X$ we associate a generalized force operator

$$\mathcal{F} = -\frac{\partial H}{\partial X}$$

(35)

Quantum stirring means to induce a circulating current by changing the parameter $X$. We assume that the parameter variation is adiabatic so we have a linear relation $\langle I \rangle = -G\dot{X}$, where $G$ is known as the geometric conductance. The Kubo formalism implies that $G$ equals to the Berry curvature:

$$G = \sum_{m(\neq n)} \frac{2 \text{ Im}[\mathcal{I}_{nm} \mathcal{F}_{mn}]}{(E_m - E_n)^2}$$

(36)

where $n$ is the level in which the particle is prepared, and $m$ are the other levels.

Within the framework of the TLS modeling the sum in Eq. (36) contains only one term which involves the states $n_0$ and $m_0$ of Eq. (6). For the matrix element of the current operator we get

$$\mathcal{I}_{n_0 m_0} = \left[ \frac{\kappa}{2} \sigma_y \right]_{n_0 m_0} = i \lambda \frac{\kappa}{2}$$

(37)

where $\lambda$ is the appropriate splitting ratio. The matrix element of the generalized force operator is calculated using Eqs. (4) and (5):

$$\mathcal{F}_{m_0 n_0} = -\frac{1}{2} \left[ \frac{\partial \sigma_z}{\partial X} \frac{\partial \kappa}{\partial X} - \frac{\partial \sigma_y}{\partial X} \frac{\partial \kappa}{\partial X} \right]_{m_0 n_0}$$

$$= \pm \frac{1}{2} \sin(\theta) \left[ \frac{\partial \sigma_z}{\partial X} - \frac{1}{2} \cos(\theta) \frac{\partial \kappa}{\partial X} \right]$$

(38)

$$= \frac{1}{2\Omega} \left( \frac{\partial \sigma_z}{\partial X} - \varepsilon \frac{\partial \kappa}{\partial X} \right)$$

(39)

where we used $\pm \sin(\theta) = \kappa/\Omega$ and $\cos(\theta) = \varepsilon/\Omega$. This leads for the following result for the geometric conductance:

$$G = \frac{\lambda \kappa}{2\Omega^3} \left[ \kappa \frac{\partial \sigma_z}{\partial X} - \varepsilon \frac{\partial \kappa}{\partial X} \right]$$

(40)

In the analysis of the operation of a stirring device we typically have a well defined region where the potential is being varied. We may call this segment “the pump”. It is convenient to measure the current elsewhere, where the potential is fixed. If barrier $A$ is not part of the “pump” then we can measure the current at $x_0 = x_A$. Then it follows from the definitions of $\lambda$ and $\kappa$ that the product $\lambda \kappa$ does not change with time, even if barrier $B$ is modulated. Then we can rewrite the above formula as

$$G = \frac{\lambda_0 \kappa_0}{2\Omega^3} \left[ \kappa_0 \frac{\partial \sigma_z}{\partial X} - \varepsilon \frac{\partial \kappa_0}{\partial X} \right]$$

(41)

where $\lambda_0$ and $\kappa_0$ are that values at some arbitrary moment of time. Typically the variation of $X$ leads to a sequence of level crossings if $\kappa$ is disregarded. These become avoided crossings if $\kappa$ is taken into account. At the vicinity of a crossing we typically can use a linear approximation:

$$\varepsilon = \dot{\varepsilon} \times (X - X_0)$$

(42)

$$\kappa = \dot{\kappa} + \dot{\varepsilon} \times (X - X_0)$$

(43)

The amount of probability $dQ = Idt$ which is being transported equals $-GdX$. For an individual crossing the $dX$ integration over $G$ can be performed using

$$\int_{-\infty}^{+\infty} \frac{a(b+cx)}{a^2x^2 + (b+cx)^2} \frac{dx}{(a^2x^2 + (b+cx)^2)^{3/2}} = \frac{2a}{b\sqrt{a^2 + c^2}}$$

(44)

$$\int_{-\infty}^{+\infty} \frac{cax}{a^2x^2 + (b+cx)^2} \frac{dx}{(a^2x^2 + (b+cx)^2)^{3/2}} = -\frac{2c^2}{ab\sqrt{a^2 + c^2}}$$

(45)

Then we get the result

$$Q = \pm \lambda_0 \sqrt{1 + (\dot{\kappa}/\dot{\varepsilon})^2}$$

(46)

where the $\pm$ is determined according to the sign of $\dot{\varepsilon}$. We observed that in order to get the “quantized” value $Q = 1$ there should be neither topological splitting ($\lambda = 1$) nor barrier modulation ($\dot{\kappa} = 0$) during the transition.
VIII. THE NEIGHBORING LEVEL APPROXIMATION SCHEME

A major interest is in systems with zero temperature Fermi occupation. In such a case Eq. (46) has to be summed over a up to the Fermi energy. It turns out [1] that the result is dominated by the contribution that come from the coupling between the last occupied level and its neighboring empty level. This suggests to adopt a neighboring level approximation scheme that holds ir-\nspective of the validity of the TLS modeling, and coincides with it if the condition of Eq. (11) is satisfied. The key idea is to characterize each eigenstate by a mixing parameter

\[ \Theta \equiv 2 \arctan \left( \frac{\text{Prob}(x = 2)}{\text{Prob}(x = 1)} \right) \]  

(48)

such that \( \Theta = 0 \) for states that belong to the first arm and \( \Theta = \pi \) for states that belong to the second arm. Numerical examples are presented in Figs. 3-4. If we are given \( \Theta \) then we can construct the eigenstate using a procedure that we describe below. If the TLS modeling applies then \( \Theta \) becomes essentially the same as \( \theta \).

Let us see how we construct the wavefunction given the energy \( E = E_n \), the mixing parameter \( \Theta = \Theta_n \), and the parity \( \pm \) with respect to (say) barrier A, as defined in Appendix A. Consequently it is convenient to set the origin such that \( x_A = 0 \), and write the \( n \)th eigenstate of the ring as

\[ \psi^{(n)}(x) = \begin{cases} \pm C_1 \sin(k_1 x + \varphi_1) & \text{if } x \in 1\text{st arm} \\ C_2 \sin(k_2 x + \varphi_2) & \text{if } x \in 2\text{nd arm} \end{cases} \]  

(49)

where \( C_1 > 0 \), and \( |\varphi| < \pi/2 \). Assuming \( k_EL \gg 1 \), the amplitudes satisfy the normalization condition

\[ \frac{1}{2}L_1C_1^2 + \frac{1}{2}L_2C_2^2 \approx 1 \]  

(50)

It follows that

\[ C_1 \approx \sqrt{\frac{2}{L_1}} \cos \left( \frac{\Theta}{2} \right) \]  

(51)

\[ C_2 \approx \sqrt{\frac{2}{L_2}} \sin \left( \frac{\Theta}{2} \right) \]  

(52)

We still have to say what are the wavenumbers \( k_1 \) and \( k_2 \), and the phase shifts \( \varphi \). Let us see first how they are determined within the framework of the TLS modeling, and then how they can be found irrespective of the TLS modeling.

Naively the \( |n_0\rangle \) and \( |m_0\rangle \) eigenstates, within the framework of the TLS modeling, are the superposition of the basis states of Eq. (4) and accordingly

\[ \Theta = \theta, \pi - \theta \]  

(53)

\[ k_1 = \text{corresponds to the unperturbed } E_1 \]  

(54)

\[ k_2 = \text{corresponds to the unperturbed } E_2 \]  

(55)

\[ \varphi_1 = \text{same as the unperturbed} \]  

(56)

\[ \varphi_2 = \text{same as the unperturbed} \]  

(57)

while the true eigenstates are with (see Fig. 2)

\[ \Theta \approx \theta, \pi - \theta \]  

(58)

\[ k_1 = \text{corresponds to } E_n \]  

(59)

\[ k_2 = \text{corresponds to } E_m \]  

(60)

\[ \varphi_1 = \text{shifted} \]  

(61)

\[ \varphi_2 = \text{shifted} \]  

(62)

To be more specific, we have \( \Theta^{(m_0)} \approx \theta \) and \( \Theta^{(n_0)} \approx \pi - \theta \) and hence \( \Theta^{(m_0)} + \Theta^{(n_0)} \approx \pi \) if the TLS modeling is valid (see Fig. 4). We note that from Eq. (51) it follows that within the framework of the TLS approximation we have

\[ C_1^{(m_0)}C_i^{(n_0)} \approx \frac{1}{L_i} \sin(\theta) \]  

(63)

This will be used later on in order to obtain simplified expressions for the matrix elements of various operators.

Whether \( k_1 \) and \( k_2 \) in Eqs. (51) \& (52) correspond to the same energy or not, is not a big difference for us because we assume \( k_1 \sim k_2 \sim k_E \) in any case. The main problem with the naive version is related to the phase shifts, as demonstrated in Fig. 2. The variation of the phase shift as the barriers are lowered reflect that there is a non-zero probability to find the particle in the region of the barriers. In particular if the phases \( \varphi_1 \) remained the same it would imply that all the matrix elements of \( I_A \) and \( I_B \) would be zero. It is essential to take the variation of \( \varphi \) into account in order to get a non-zero result for the geometrical conductance. We shall discuss the calculation of the matrix elements \( I_{nm} \) and \( F_{nm} \) in the next sections.

First we would like to discuss how the required information on the variation of the phases \( \varphi \) can be extracted.

In order to express \( \varphi \) by \( \Theta \), we write the wave function of Eq. (31) as ingoing and outgoing waves and set the origin \( x = 0 \) at either one of the barriers, for example barrier A. We match the wave functions of the two bonds by the barrier scattering matrix

\[ \begin{pmatrix} \pm C_1 e^{i\varphi_1} \\ C_2 e^{i\varphi_2} \end{pmatrix} = S_A \begin{pmatrix} \pm C_1 e^{-i\varphi_1} \\ C_2 e^{-i\varphi_2} \end{pmatrix} \]  

(64)

and get closed equations for the phase shifts

\[ \sqrt{1 - g\sin(2\varphi_1 - \alpha - \gamma)} = 1 - \frac{g}{2} \left( 1 + \frac{C_2}{C_1} \right)^2 \]  

(65)

\[ \sqrt{1 - g\sin(2\varphi_2 + \alpha - \gamma)} = 1 - \frac{g}{2} \left( 1 + \frac{C_1}{C_2} \right)^2 \]  

(66)

So far everything is exact. So once we have \( \Theta \), we can find the phases and construct the wavefunction. We would like to focus in the rest of this section in the regime where the TLS modeling applies. Assuming that \( \Theta \) is determined by \( \theta \) we want to find what are \( \varphi_1 \) and \( \varphi_2 \), so as to construct a proper wavefunction. Neglecting terms of order \( g \) and expanding \( \arcsin(1-x) \) as \( \pi/2 \pm \sqrt{2x} \) we obtain

\[ \varphi_1 \approx \frac{\gamma + \alpha}{2} + \frac{\pm \sqrt{g}}{2} \sqrt{\frac{L_1}{L_2}} \tan \left( \frac{\Theta}{2} \right) \]  

(67)
where the ± sign should be the same as in Eq. [63], which can be established by direct substitution. A similar expression can be obtained for \( \varphi_2 \). We note that within the framework of this TLS approximation we have

\[
\varphi_1^{(m_0)} - \varphi_1^{(0)} = \pm \sqrt{g_A} \left( \frac{L_1}{L_2} \right)^{1/2} \frac{1}{\sin(\theta)} \tag{68}
\]

where the sign is the same as that of \( \kappa \). We now have all the building blocks needed for the calculation of the matrix elements.

**IX. THE EXPRESSION FOR \( \mathcal{I}_{nm} \)**

If we adopt the TLS point of view, we can postulate a self-consistent definition of the current operator based on the continuity equation. For this purpose we define the occupation operator \( \mathcal{N} \) for one of the arms as

\[
\mathcal{N} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \tag{69}
\]

and deduce the definition of the current operator from

\[
\frac{d}{dt} \mathcal{N} = i [\mathcal{H}, \mathcal{N}] = \mathcal{I} \tag{70}
\]

where \( \mathcal{I} \) is given by Eq. [12]. If we turn off the coupling at barrier A we get the same expression multiplied by \( \lambda_B \), while if we turn off the coupling at barrier B we get the same expression multiplied by \( \lambda_A \).

The above reasoning bypass the confrontation which is involved in carrying out a direct calculation, and hence contains an uncontrolled error which is associated with the assumption that a TLS description of Hilbert space is valid. If we revert to the original definition of Eq. [2], then the matrix elements are given by

\[
\mathcal{I}_{nm} = \frac{i}{2m} \left( \partial \psi^{(n)} \psi^{(m)} - \partial \psi^{(m)} \psi^{(n)} \right) \bigg|_{x=x_0} \tag{71}
\]

For the calculation of \( \mathcal{I}_{nm}^A \) we set \( x_0 = x_A = 0 \). As was already pointed out, in order to get a non-trivial result, we have to take into account the phase shifts \( \varphi \) which was calculated in the previous section. Substituting the wave function of Eq. [10] we get

\[
\mathcal{I}_{nm}^A = -\frac{i}{2m} \alpha^r_m \alpha^l_m \left[ \frac{k_m + k_n}{2} \sin(\varphi^{(m)} - \varphi^{(n)}) + \frac{k_n - k_m}{2} \sin(\varphi^{m} + \varphi^{n}) \right] \tag{72}
\]

Whenever the TLS modeling applies we can substitute Eqs. [63] and [68] into Eq. [72]. Neglecting the second term we get

\[
\mathcal{I}_{nm}^A \approx \mp i \frac{v}{2\sqrt{L_1L_2}} \sqrt{g_A} \tag{73}
\]

where the sign is the same as that of \( -\kappa \). One notices that the expression for \( \mathcal{I}_{nm}^A \) can be written as Eq. [37] where \( \kappa \) and \( \lambda \) are given by Eq. [7] and Eq. [13].

**X. STIRRING BY BARRIER MODULATION**

In this section we calculate the geometric conductance as determined by the matrix elements of the generalized force that is associated with modulation of a delta barrier. The motivation is to verify the results of the reduced description against the direct full Hilbert space calculation. The potential barrier is given by

\[
V_B(\hat{x}) = X_B \delta(\hat{x} - x_B) \tag{74}
\]

The stirring is induced by variation of the barrier height \( X_B \). The associated generalized force is

\[
\mathcal{F} = -\frac{\partial \mathcal{H}}{\partial X_B} = -\delta(\hat{x} - x_B) \tag{75}
\]

with the matrix elements

\[
\mathcal{F}_{nm} = -\psi^{(n)}(\hat{x}) \psi^{(m)}(\hat{x}) \tag{76}
\]

For the wavefunctions amplitudes we use Eq. [63] and for the phase shifts Eq. [67]. We also substitute the scattering matrix parameters that describe a delta barrier

\[
\gamma_B \approx -\pi/2 + \sqrt{g_B} \tag{77}
\]

\[
\alpha_B = 0 \tag{78}
\]

where the approximation is valid for \( g_B \ll 1 \) and the relation of \( g_B \) and \( X_B \) is given in Eq. [21]. With the above approximations we get

\[
\mathcal{F}_{nm} \approx g_B \frac{L_2 - L_1}{4L_1L_2} \sin(\theta) \mp g_B \frac{g_B}{2\sqrt{L_1L_2}} \cos(\theta) \tag{79}
\]

where the sign should be the same as that of \( \mp \kappa \). In order to verify the consistency with the TLS expression, we differentiate Eq. [60] and Eq. [7]:

\[
\frac{\partial \varphi}{\partial X_B} = \frac{g_B L_2 - L_1}{2L_1L_2} \tag{80}
\]

\[
\frac{\partial \varphi}{\partial X_B} = \pm \frac{g_B}{\sqrt{L_1L_2}} \tag{81}
\]

and substitute into Eq. [68]. Indeed we obtain the same result for \( \mathcal{F}_{nm} \) as above.

The geometric conductance of Eq. [60] involves the multiplication of \( \mathcal{F}_{nm} \) with \( \mathcal{I}_{nm} \), leading to

\[
G = \frac{1}{4} \frac{v}{\Omega^2} \frac{L_2 - L_1}{(L_1L_2)^2} \frac{g_A g_B \pm g_A^{1/2} g_B^{3/2}}{\Omega^3} \tag{82}
\]

The calculation of the transport proceeds as in Section VII.
XI. STIRRING BY BARRIER TRANSLATION

In complete analogy with the previous section we would like to calculate the geometric conductance as determined by the matrix elements of the generalized force which is associated with the translation of the barrier:

$$ F = -\frac{\partial H}{\partial \psi_B} = X_B \delta'(\hat{x} - x_B) $$

(83)

One obtains

$$ F_{mn} = -X_B \left( \frac{\partial \psi_1^{(n)}}{\partial \psi_B^{(m)}} + \frac{\partial \psi_B^{(m)}}{\partial \psi_1^{(n)}} \right) $$

(84)

where $\partial \psi$ is the average derivative on both sides of the barrier. We simplify this expression by using Eq. (19):

$$ F_{mn} = \frac{1}{2m} \left[ \frac{\partial \psi_1^{(m)}}{\partial \psi_1^{(n)}} - \frac{\partial \psi_2^{(m)}}{\partial \psi_2^{(n)}} \right]_{x=x_B} $$

(85)

Assuming high barriers we get in leading order

$$ F_{mn} \approx -\frac{1}{2m} \frac{E_1^{(m)} C_1^{(n)} + C_2^{(m)} C_2^{(n)}}{L_1 L_2} \sin(\theta) $$

(86)

which together with Eq. (63) leads to

$$ F_{mono} \approx -\frac{1}{2} m v_E^2 \frac{L_1 + L_2}{L_1 L_2} \sin(\theta) $$

(87)

In order to compare the above result for $F_{mono}$ with the TLS result of Eq. (38) we calculate the variation of the potential floor by taking in Eq. (60) the energies of infinite wells with $L_1 = x_B$ and $L_2 = L - x_B$. We get

$$ \frac{\partial \epsilon}{\partial x_B} = -m v_E^2 \frac{L_1 + L_2}{L_1 L_2} + O(\sqrt{g}) $$

(88)

$$ \frac{\partial \kappa}{\partial x_B} = v_E \frac{L_2 - L_1}{(L_1 L_2)^{3/2}} \sqrt{gA} \pm \sqrt{gb} $$

(89)

Substitute into Eq. (38) indeed leads to the same result for $F_{mono}$ as above. Note that in this case (unlike the previous section) the second term in Eq. (88) which involves the variation of $\kappa$ is of higher order in $gb$ and therefore should be excluded.

The geometric conductance of Eq. (88) involves the multiplication of $F_{mono}$ with $\zeta_{mono}$, leading to

$$ G = -\frac{1}{2} \sqrt{gA} m v_E^2 \frac{L_1 + L_2}{(L_1 L_2)^2} \sqrt{gA} \pm \sqrt{gb} \Omega^3 $$

(90)

The calculation of the transport proceeds as in Section VII. One realizes that a translation of the barrier is effectively equivalent to the variation of the potential floor difference, as long as it does not involve modulation of its transmission (which is assumed to be small).

XII. ERROR ESTIMATES AND LIMITATIONS

If we vary a parameter $X$ then the energy levels $E_n(X)$ form a “spaghetti” which is characterized by a mean level spacing $\Delta$ and possibly by narrow avoided crossings with splitting $\Delta_0$. For the ring system that we are considering it follows from the estimate of $\kappa$ that

$$ \frac{\Delta_0}{\Delta} \sim \min\{1, \sqrt{bg}\} $$

(91)

where $b = L_1/L_2$ and $g = \max\{gA, gb\}$. The condition Eq. (11) for the applicability of the TLS modeling ensures $\Delta_0 \ll \Delta$. In such circumstances Eq. (36) for the geometric conductance, which in essence is a sum of the type $\sum_{n=0}^{\infty} (\Delta_0 + n\Delta)^{-2}$, implies that the error that is involved in the neighboring level approximation is

$$ \text{error}(G) \sim \left( \frac{\Delta_0}{\Delta} \right)^2 \sim bg \ll 1 $$

(92)

Once the TLS modeling fails the error becomes of order unity. This sounds bad, but in fact it is not so bad. The good news is that the far levels contribute to $G$ a correction which is of the same order as the leading term. Therefore with the neighboring level approximation we can still get a realistic estimate disregarding numerical prefactors of order unity.

Having $b \gg 1$ is very interesting, because then we have a non-trivial intermediate regime $1/b \ll g \ll 1$ where neither 1st order perturbation theory with respect to “zero” height barriers, nor 1st order perturbation theory with respect to “infinite” barriers applies. This is the regime where each level of the small arm forms a distinct Wigner resonance with the quasi-continuum states of the long arm. Obviously the TLS modeling is not applicable in this regime, but the neighboring level approximation still provides a decent starting point for a calculation. We shall explore this Wigner regime in a future work.

One may also wonder whether the specific results that we have obtained for stirring using a delta barrier applies also for a thick barrier. On physical grounds it is quite obvious that the induced current is determined by the scattering matrix of the modulated barrier. Consequently if the $S(E)$ of the modulated barrier is $E$ independent within the energy range of interest, it can be regarded as representing a delta function, and the results should come out the same.

Finally one may wonder about the implications of finite temperature or non-adiabatic driving. These aspects are complementary to the theme of the present paper. Namely, as discussed in [1], at finite temperatures the statistics of the occupation should be taken into account. So we have to average (so to say) over the level that we have labeled as $n_0$ with an appropriate weight as implied by the Fermi function. On the other hand the non-adiabatic effects require to introduce in the denominator of the Kubo formula Eq. (38) a term that represents the “width” of the Fermi-golden-rule transitions. Then the weight of the neighboring level in the sum becomes smaller compared with the total weight of the far levels.
XIII. SUMMARY

We have developed a practical procedure for the analysis of a one dimensional double well system, which is both powerful and illuminating. The procedure assumes that we have a way to find the eigen-energies $E_n$ of the device, and the mixing ratio $\Theta_n$ of each of them. Given the transmissions of the barriers we further characterize the device by the splitting ratio $\lambda$. With these ingredients in hand we can analyze any stirring process and obtain explicit expressions for the geometric conductance $G$. The calculation simplifies if the TLS modeling applies, because then the mixing ratio can be determined form the diagonalization of a $2 \times 2$ matrix.

In particular we obtain explicit expressions for $G$ due to either barrier translation (generalizing a result that has been obtained in [1]), or barrier modulation (generalizing a result that has been obtained in [2]), and verify that they agree with the naive self-consistent TLS calculation. We see that whenever the TLS modeling applies the proper calculation in the full Hilbert space gives the same result as the naive calculation in the TLS Hilbert space.

As a by product of the TLS analysis we find that the pumped “charge” during an avoided crossing is not quantized (see Eq. (17)), not only because of the topological splitting effect, but also due to a dynamical effect that arises if the barrier is modulated.

The practical importance of the TLS modeling in condensed matter physics is obvious. On the other hand the specific application to the study of quantum stirring deserves a few words regarding the measurement procedure and the experimental relevance. As explained in [1] it should be clear that the measurement of current in a closed circuit requires special techniques [12,13,14]. These techniques are typically used in order to probe persistent currents, which are zero order (conservative) effect, while in the present paper we were discussing driven currents, which are a first-order (geometric) effect. It is of course also possible to measure the dissipative conductance (as in [12]). During the measurement the coupling to the system should be small. These are so called weak measurement conditions. More ambitious would be to measure the counting statistics, i.e. also the second moment of $Q$ as discussed in [15,16] which is completely analogous to the discussion of noise measurements in open systems [17,18]. Finally it should be pointed out that the formalism above, and hence the results, might apply to experiments with superconducting circuits (see [19]).

The unperturbed eigenstates are labeled by $i$ (or optionally by $j$). In the TLS scheme $i = 1, 2$. If the coupling is non-zero the exact eigenstates are labeled by $n$ (or optionally by $m$). Within the framework of the neighboring level approximation scheme we focus on two levels that we label as $n = n_0$ and $m = m_0$. If the TLS modeling applies then the states $n_0$ and $m_0$ are regarded as linear combinations of $i = 1, 2$.

The unperturbed states $i = 1, 2$ are characterized by their parities $\pm \delta$ and $\pm \delta'$ respectively. The relative sign $\pm$ in Eq. (7) equals the product of $\pm \delta$ and $\pm \delta'$. Inverting the arbitrary gauge sign of either $\psi^{(1)}(x)$ or $\psi^{(2)}(x)$ would multiply the expression in Eq. (6) by a global minus sign, while the relative sign $\pm$ remains unchanged. The gauge invariant relative sign is due to the fact that the unperturbed states are either odd or even: we have plus sign if both states have the same parity and minus sign if they have opposite parity.

Each exact eigenfunction $n$, as written as in Eq. (19), is characterized by what we call the parity $\pm \delta$ with respect to barrier A. Positive parity means that the radial derivatives as defined in Eq. (19) have both the same sign. The unperturbed states $i = 1, 2$ are characterized by their parities $\pm \delta$ and $\pm \delta'$ respectively. The relative sign $\pm$ in Eq. (7) equals the product of $\pm \delta$ and $\pm \delta'$. Inverting the arbitrary gauge sign of either $\psi^{(1)}(x)$ or $\psi^{(2)}(x)$ would multiply the expression in Eq. (6) by a global minus sign, while the relative sign $\pm$ remains unchanged. The gauge invariant relative sign is due to the fact that the unperturbed states are either odd or even: we have plus sign if both states have the same parity and minus sign if they have opposite parity.

We have verified that the various $\pm$ signs through the paper are consistent, which is not always evident in a superficial look.

FIG. 1: Panel (a): Illustration of a ring shaped device that is divided by the barriers $V_A$ and $V_B$ into two arms of length $L_1$ and $L_2$. The current is measured through the dashed section near barrier $A$. In the quantum stirring scenario it is assumed that there is a gate control over the potential floor of each arm, or over the height or the location of barrier $B$. Panel (b): Within the framework of the TLS modeling, the reduced Hilbert space contains two levels. The perturbation $W_{ij}$ is due to having finite rather than infinite barriers, so it corresponds to the difference $H - H(\infty)$ and not to $V = H - H(0)$. See the text for further details.

FIG. 2: Upper panel: Two nearly degenerate eigenfunctions $\psi(x)$ of a particle in a ring with arms of length $L_1 = 1$ and $L_2 = 2.23$. These are the two unperturbed states of Eq. (4). Lower panel: The exact eigenfunctions assuming that the barriers are finite ($g_A \approx 0.28$ and $g_B \approx 0.06$). These do not vanish at the barriers, and therefore cannot be written as a superposition of the unperturbed states. Still we explain in the text how a decent approximation for the former can be obtained using the neighboring levels approximation scheme.

FIG. 3: We consider a particle of mass $m = 1$ in a ring of length $L = 151.43$. The position of barrier $B$ is $X$, so we have $L_1 = X$ and $L_2 = L - X$. We calculate numerically $k_n$ and $\Theta^{(n)}$ for two neighboring levels (solid and dashed lines). The sum $\Theta^{(m)} + \Theta^{(n)}$ is plotted as a dash-dotted line. We have high barriers with $g_A \sim 10^{-2}$ and $g_B \sim 10^{-5}$. Accordingly we expect TLS modeling to be valid: The dotted lines indicate the values $\Theta = \pi/2$ (expected crossing point) and $\Theta = \pi$ (expected sum). For sake of comparison there is a third dotted line that indicates the value of $\Theta$ that corresponds to equal amplitudes $C_1 = C_2$.

FIG. 4: The same as the previous figure, but here the TLS modeling does not apply. In the left panels one barrier is high ($g_A \sim 10^{-2}$) and one barrier is low ($g_B \sim 0.9$), while in the right panels both barrier are low ($g_A \sim g_B \sim 0.9$).
