Keywords: Weyl fermions, renormalization group, interaction driven instabilities, chiral superconductors, pomeranchuk

Abstract

We study Weyl-loop semi-metals with short range interactions, focusing on the possible interaction driven instabilities. We introduce an $\epsilon$ expansion regularization scheme by means of which the possible instabilities may be investigated in an unbiased manner through a controlled weak coupling renormalization group (RG) calculation. The problem has enough structure that a ‘functional’ RG calculation (necessary for an extended Fermi surface) can be carried out analytically. The leading instabilities are identified, and when there are competing degenerate instabilities a Landau–Ginzburg calculation is performed to determine the most likely phase. In the particle-particle channel, the leading instability is found to be to a fully gapped chiral superconducting phase which spontaneously breaks time reversal symmetry, in agreement with general symmetry arguments suggesting that Weyl loops should provide natural platforms for such exotic forms of superconductivity. In the particle hole channel, there are two potential instabilities—to a gapless Pomeranchuk phase which spontaneously breaks rotation symmetry, or to a fully gapped insulating phase which spontaneously breaks mirror symmetry. The dominant instability in the particle hole channel depends on the specific values of microscopic interaction parameters.

1. Introduction

The most generic metallic states occur in systems that host Fermi surfaces whose dimension is one less than the dimension of the system. In the presence of effective short-range interactions among the fermions, these metallic states are described by the Tomonaga–Luttinger model in one dimension [1–7], and frequently by Landau’s Fermi liquid theory above one dimension [8]. Comparatively less common metallic states are realized in systems where a filled valence band touches a conduction band. These semi-metallic states possess gapless excitations about a zero-energy manifold with dimension two or more below the spatial dimension of the system. Although semi-metals have been theoretically investigated since at least 1970s [9], their properties have garnered considerable interest in the last two decades with the advent of graphene [10–12] and other varieties of Dirac materials [13–28]. Most of the known semi-metals contain a discrete set of gapless points in the bulk. However, in recent years, three dimensional semi-metals with a ring of gapless points have become a possibility [29–39]. Theoretical investigation into the effect of the weakly screened long-range Coulomb interaction on these Weyl-loop semi-metals suggests that single-particle excitations survive at low energy, as quantum fluctuations render the Coulomb interaction marginally irrelevant [40]. In contrast, strong short-range interactions can lead to symmetry-breaking instabilities. Indeed, it has been argued that such ‘Weyl loop’ systems may serve as ideal playgrounds for realizing exotic forms of superconductivity [41, 42]. However, a systematic and unbiased analysis of the potential interaction driven instabilities of Weyl loop systems remains to be performed.

In this paper we investigate the effect of short-range interactions on a Weyl-loop semi-metal, and identify the symmetry broken states that are probable at finite interactions.

The paper is organized as follows. In section 2 we introduce the continuum model whose low energy properties are the subject of this work. A generalization based on tuning the dispersion of the fermions is developed, which enables access to finite coupling instabilities within the regime of applicability of a controlled
weak coupling perturbation theory. In sections 3 to 5 the low energy properties of the perturbatively accessible sector of the generalized model is analyzed within a renormalization group (RG) scheme based on mode elimination. The RG is shown to have enough structure that a ‘functional’ analysis (necessary for an extended Fermi surface) can be carried out analytically. The particle–particle and particle–hole channels are found to decouple. We deduce the fixed points of the running couplings in the particle–particle and particle–hole channels respectively. In section 4.3 the most likely instability is identified through an analysis of anomalous dimensions of the susceptibilities of various pairing channels, combined with a Landau–Ginzburg analysis. In the particle particle channel we find an instability to a novel form of superconductivity, wherein the order parameter is fully gapped and chiral, and spontaneously breaks time reversal symmetry. In the particle–hole channel there are two potential instabilities (with the dominant one being determined by microscopic values of interaction parameters): either a Pomeranchuk instability to a gapless phase that spontaneously breaks rotation symmetry, or an excitonic instability to a gapped (trivial) insulating state that spontaneously breaks mirror symmetry. Finally, in section 6 we conclude with a discussion of our results.

2. Model

In this section we derive an effective theory that is appropriate for understanding the universal low energy properties of the Weyl-loop semi-metal in the presence of short range interactions. Since short range interactions are expected to be strongly irrelevant in the presence of linear band-touching, we develop a convenient generalization of the model in terms of the degree of band-curvature, which allows us to access interaction driven instabilities within the regime of applicability of a weak coupling RG.

2.1. Non-interacting theory

The simplest realistic description of non-interacting fermions whose dispersion admits a nodal line Fermi surface in three dimensions is given by [40, 42]

\[ S_0 = \int \! d\mathbf{K} \; \Psi^\dagger(K)[i\mathbf{k}_0\sigma_0 + E(K)]\Psi(K), \]

where \( \mathbf{dK} \equiv \frac{d\mathbf{k}_0 d\mathbf{K}}{(2\pi)^3} \), \( \mathbf{k}_0 \) is the Euclidean (Matsubara) frequency, \( \mathbf{K} \) denotes three dimensional momentum, \( \sigma_0 \) is the \( 2 \times 2 \) identity matrix, and \( \Psi(K) = (\psi_1(K), \psi_2(K)) \) is a spinor representing fermions \( \alpha = 1, 2 \).

The dispersion is

\[ E(K) = \sqrt{\mathbf{v}_1^2(K) + \mathbf{v}_2^2(K)}, \]

where \( \mathbf{v}_1(K) = (|K| + \kappa)/2m \). Here we have distinguished between the three dimensional momentum from its projection, \( \vec{K} \) on the plane of the Weyl-loop. We have chosen the loop to lie on the \( x–y \) plane, and it is defined by \( |\vec{K}| = \sqrt{K_x^2 + K_y^2} = \kappa \). Here \( \sigma_1 \) and \( \sigma_2 \) are the first two Pauli matrices which encode the orbital degrees of freedom, and \( m \) and \( v \) are bandstructure parameters. We note that at finite doping, i.e. away from perfect compensation, the non-interacting theory is modified by replacing \( i\mathbf{k}_0 \mapsto ik_0 - \mu \). Our theory will focus on \( \mu = 0 \).

Diagonalizing \( E(K) \) yields two bands that disperse as

\[ \xi_{\pm}(K) = \pm \sqrt{v_1^2(K) + \mathbf{v}_2^2(K^2)} \]

Since the chemical potential \( \mu = 0 \), the ground state is defined by the configuration where \( |\vec{K}| = \kappa \) and \( K_z = 0 \), which precisely corresponds to the loop. Thus at low energy \( |\vec{K}| \approx \kappa \) and \( K_z \approx 0 \), and the dispersion, equation (2), can be approximated to

\[ E(k_x, k_z) = v_1 k_x + v_2 k_z \sigma_2, \]

where \( \mathbf{v}_1 = \kappa/m \) and \( k_x \equiv |\vec{K}| - \kappa \) and \( k_z \) are deviations of momentum in the radial and \( z \) directions, respectively. The band dispersion simplifies to \( \xi_{\pm}(k_x, k_z) = \pm \sqrt{v_1^2 k_x^2 + v_2^2 k_z^2} \).

We scale \( (k_0, k_z) \mapsto \nu (k_0, k_z) \), and identify the long wavelength fluctuations of the fermions (low energy modes) through the relation,

\[ \Psi(\tau, \mathbf{r}) = e^{i\mathbf{k}_0 \cdot \mathbf{r}} \psi(\tau, \mathbf{r}) + \text{fast modes}, \]

where \( \mathbf{k}_0 = \kappa (\cos \theta, \sin \theta, 0) \) with \( \theta \) specifying the position on the loop. We further sharpen the definition of the low energy modes by requiring that the momentum carried by these modes to be such that

\[ \sqrt{k_x^2 + k_z^2} < \Lambda \ll \kappa, \]

where \( \Lambda \) is a UV cutoff on the \( k_x - k_z \) plane, measured from the loop (see figure 1). Integrating out the modes which modulate over length scales \( \lesssim \Lambda^{-1} \) we obtain
where $f_1(k_1, k_2)$ is a cutoff function which suppresses modes with $k_1^2 + k_2^2 \geq A^2$. We choose $f_1(k_1, k_2)$ to be rotationally symmetric in $k_1 - k_2$ plane. The two dimensional vector $\vec{k}$ is the deviation of momentum from the loop, and is defined on the $k_1 - k_2$ plane by $\vec{k} \equiv (k_1, k_2)$. We emphasize that $\vec{k}$ is not linearly related to the deviations from the loop in $\mathbf{K}$ space. In particular, under inversion $\mathbf{K} \rightarrow -\mathbf{K}$, but $\vec{k} = (k_1, k_2) \mapsto (k_1, -k_2)$.

2.1.1. Symmetries

The dynamics of the non-interacting fermions described by equation (6) enjoys a set of continuous and discrete symmetries. In this section we describe these symmetries, and the respective symmetry transformations.

Since the fermion dynamics is independent of the position of the fermionic momentum on the loop, the loop coordinate $\theta$ acts as a label for the $\psi$ fields. The cyclic nature of $\theta$ leads to three continuous symmetries of $S_0$. The first is a SO(2) rotational invariance of the action under $\mathcal{R}_\theta : \theta \rightarrow \theta + \theta_0$. In order to isolate the second symmetry let us write the spatial part of the propagator in terms of polar coordinates $(k_1, \varphi)$ as $k \cos \phi \sigma_1 + \sin \varphi \sigma_2$, where $(k_1, k_2) = (k \cos \varphi, k \sin \varphi)$. Under the transformation $\mathcal{R}_\varphi : \psi \rightarrow e^{i\varphi \sigma_3} \psi$, with $\varphi = \sigma_3 k^2/2 - i \varphi_3$, the lagrangian

$$L_0[k_0, k, \theta, \varphi; \psi] = \psi^\dagger (k_0, k, \theta, \varphi) [i k_0 \sigma_0 + k (\cos \varphi \sigma_1 + \sin \varphi \sigma_2)] \psi (k_0, k, \theta, \varphi)$$

transforms to $L_0[k_0, k, \theta, \varphi + \xi_0; \psi]$, implying $\mathcal{R}_\varphi$ is a symmetry of $S_0$. $\mathcal{R}_\varphi$ corresponds to a rotation in the plane perpendicular to the loop at each point $\theta$. The third symmetry is the invariance of the action under a $\theta$-dependent $U(1)$ transformation $\psi \rightarrow e^{i\varphi \sigma_3} \psi$. Since the latter two symmetry transformations are locally defined on the loop, they lead to distinct emergent $U(1)_\theta$ symmetries which we will distinguish as pseudospin-$U(1)_\theta$ charge-$U(1)_\Omega$ respectively. While the former corresponds to the conservation of $\theta$ component of total angular momentum, the latter originates from particle number conservation at each $\theta$. We note that the charge-$U(1)_\Omega$ symmetry is present in any non-interacting theory where the single particle dispersion is minimized on a plane perpendicular to the loop at each point $\theta$. The cyclic nature of $\theta$ leads to three continuous symmetries of $S_0$, $\mathcal{R}_\theta$, $\mathcal{R}_\varphi$, and $\mathcal{R}_\Omega$.

The action is also invariant under three sets of discrete transformations. The first is a mirror-plane symmetry which originates from the symmetry between the dynamics above and below the $\mathbf{K}$ space. Since the latter two symmetry transformations are locally defined on the loop, they lead to distinct emergent $U(1)_\theta$ symmetries which we will distinguish as pseudospin-$U(1)_\theta$ charge-$U(1)_\Omega$ respectively. While the former corresponds to the conservation of $\theta$ component of total angular momentum, the latter originates from particle number conservation at each $\theta$. We note that the charge-$U(1)_\Omega$ symmetry is present in any non-interacting theory where the single particle dispersion is minimized on a plane perpendicular to the loop at each point $\theta$. The cyclic nature of $\theta$ leads to three continuous symmetries of $S_0$, $\mathcal{R}_\theta$, $\mathcal{R}_\varphi$, and $\mathcal{R}_\Omega$.

The action is also invariant under three sets of discrete transformations. The first is a mirror-plane symmetry which originates from the symmetry between the dynamics above and below the $\mathbf{K}$ space. Since the latter two symmetry transformations are locally defined on the loop, they lead to distinct emergent $U(1)_\theta$ symmetries which we will distinguish as pseudospin-$U(1)_\theta$ charge-$U(1)_\Omega$ respectively. While the former corresponds to the conservation of $\theta$ component of total angular momentum, the latter originates from particle number conservation at each $\theta$. We note that the charge-$U(1)_\Omega$ symmetry is present in any non-interacting theory where the single particle dispersion is minimized on a plane perpendicular to the loop at each point $\theta$. The cyclic nature of $\theta$ leads to three continuous symmetries of $S_0$, $\mathcal{R}_\theta$, $\mathcal{R}_\varphi$, and $\mathcal{R}_\Omega$.

The action is also invariant under three sets of discrete transformations. The first is a mirror-plane symmetry which originates from the symmetry between the dynamics above and below the $\mathbf{K}$ space. Since the latter two symmetry transformations are locally defined on the loop, they lead to distinct emergent $U(1)_\theta$ symmetries which we will distinguish as pseudospin-$U(1)_\theta$ charge-$U(1)_\Omega$ respectively. While the former corresponds to the conservation of $\theta$ component of total angular momentum, the latter originates from particle number conservation at each $\theta$. We note that the charge-$U(1)_\Omega$ symmetry is present in any non-interacting theory where the single particle dispersion is minimized on a plane perpendicular to the loop at each point $\theta$. The cyclic nature of $\theta$ leads to three continuous symmetries of $S_0$, $\mathcal{R}_\theta$, $\mathcal{R}_\varphi$, and $\mathcal{R}_\Omega$.

The action is also invariant under three sets of discrete transformations. The first is a mirror-plane symmetry which originates from the symmetry between the dynamics above and below the $\mathbf{K}$ space. Since the latter two symmetry transformations are locally defined on the loop, they lead to distinct emergent $U(1)_\theta$ symmetries which we will distinguish as pseudospin-$U(1)_\theta$ charge-$U(1)_\Omega$ respectively. While the former corresponds to the conservation of $\theta$ component of total angular momentum, the latter originates from particle number conservation at each $\theta$. We note that the charge-$U(1)_\Omega$ symmetry is present in any non-interacting theory where the single particle dispersion is minimized on a plane perpendicular to the loop at each point $\theta$. The cyclic nature of $\theta$ leads to three continuous symmetries of $S_0$, $\mathcal{R}_\theta$, $\mathcal{R}_\varphi$, and $\mathcal{R}_\Omega$.

The action is also invariant under three sets of discrete transformations. The first is a mirror-plane symmetry which originates from the symmetry between the dynamics above and below the $\mathbf{K}$ space. Since the latter two symmetry transformations are locally defined on the loop, they lead to distinct emergent $U(1)_\theta$ symmetries which we will distinguish as pseudospin-$U(1)_\theta$ charge-$U(1)_\Omega$ respectively. While the former corresponds to the conservation of $\theta$ component of total angular momentum, the latter originates from particle number conservation at each $\theta$. We note that the charge-$U(1)_\Omega$ symmetry is present in any non-interacting theory where the single particle dispersion is minimized on a plane perpendicular to the loop at each point $\theta$. The cyclic nature of $\theta$ leads to three continuous symmetries of $S_0$, $\mathcal{R}_\theta$, $\mathcal{R}_\varphi$, and $\mathcal{R}_\Omega$.

The action is also invariant under three sets of discrete transformations. The first is a mirror-plane symmetry which originates from the symmetry between the dynamics above and below the $\mathbf{K}$ space. Since the latter two symmetry transformations are locally defined on the loop, they lead to distinct emergent $U(1)_\theta$ symmetries which we will distinguish as pseudospin-$U(1)_\theta$ charge-$U(1)_\Omega$ respectively. While the former corresponds to the conservation of $\theta$ component of total angular momentum, the latter originates from particle number conservation at each $\theta$. We note that the charge-$U(1)_\Omega$ symmetry is present in any non-interacting theory where the single particle dispersion is minimized on a plane perpendicular to the loop at each point $\theta$. The cyclic nature of $\theta$ leads to three continuous symmetries of $S_0$, $\mathcal{R}_\theta$, $\mathcal{R}_\varphi$, and $\mathcal{R}_\Omega$.
second element of the pair is obtained by combining $P_0$ with $P_1$. We summarize all the symmetries of $S_0$ in table 1.

2.1.2. Generalization
As we will show later in the paper, in order to obtain a controlled truncation of the beta functions of various operators it is convenient to generalize the linear band-touching model to higher order band-touchings. We use the polar coordinates introduced in section 2.1.1 to generalize the dispersion of fermions as $\varepsilon_0(k, \varphi) = k^n (\cos \varphi \sigma_1 + \sin \varphi \sigma_2)$ for any real number $\eta > 0$. The band dispersion is modified accordingly as $\xi_{\text{int}}(k, \varphi) = \pm k^n$. Thus, the dynamics of the non-interacting fermions with $\eta$-th order band-touching is given by

\[
S_{\eta=0} = \frac{\psi^\dagger \psi}{\nu_2} \int_{-\pi}^{\pi} \frac{d\theta \, d\varphi}{2\pi^2} \int_{-\infty}^{\infty} \frac{d k_0}{2\pi} \int_{-\infty}^{\infty} \frac{d k}{2\pi} f_\mu(k) \psi k_0, k, \theta, \varphi) [i k_0 \sigma_0 + k^n (\cos(\varphi) \sigma_1 + \sin(\varphi) \sigma_2)] \psi(k_0, k, \theta, \varphi),
\]

(8)

Since the value of $\eta$ does not affect the symmetry transformations, $S_{\eta=0}$ and $S_{1,0}$ share the same set of symmetries. The Gaussian fixed point described by $S_{\eta=0}$ is invariant under the following choice of scaling,

\[
[\theta], [\varphi] = 0, \quad [k] = 1, \quad [k_0] = \eta, \quad [\psi] = -(\eta + 1),
\]

(9)

where the quantity $X$ scales as $X' = e^{[X]} d'X$ with $d'$ being a logarithmic momentum scale. We note that within our scheme the radius of the loop ($\kappa$) is dimensionless, which implies coarse-graining towards the loop in momentum space [43, 44].

2.2. Interactions
In this section we introduce the vertices describing instantaneous short-range interactions that are consistent with the discrete symmetries of the non-interacting theory. After scaling $k_0$ and $K_{\text{int}}$ as was done for $S_0$, to obtain

\[
\begin{align*}
S_{\text{int}} &= \left( \frac{\psi^\dagger \psi}{\nu_2} \right)^3 \sum_{\mu, \nu = 0}^{4} \int \Delta \left( \prod_{n=1}^{4} d K_n \right) (2\pi)^4 \delta^{(4)}(K_1 - K_2 + K_3 - K_4) U_{\mu, \nu}(\{K_n\}) \\
&\quad \times \left[ \psi^\dagger(K_1) \sigma_\mu \psi(K_2) \right] \left[ \psi^\dagger(K_3) \sigma_\nu \psi(K_4) \right],
\end{align*}
\]

(10)

where $\int \Delta d K = \int d K f_\mu(\{K_n\}) - \kappa, K_2)$. We assume $U_{\mu, \nu}(\{K_n\}) = U_{\mu, \nu}(\{K_n\})$ to be real valued functions of momentum. In general, there are 16 vertices corresponding to four choices each for $\mu$ and $\nu$. In this paper we focus on only those vertices that are invariant under the discrete symmetries of $S_0$, viz, $P_2$, $P_3$, and $P_4$. The terms that have odd parity under these symmetries are marked with corresponding labels in table 2. From the table we see that only those terms for which $\mu = \nu$ have the same parity as $S_0$. Thus, the minimal set of interactions that respect the discrete symmetries of $S_0$ is given by

\[
\begin{align*}
\hat{S}_{\text{int}} &= \frac{\psi^\dagger \psi}{\nu_2} \int \Delta \left( \prod_{n=1}^{4} d K_n \right) (2\pi)^4 \delta^{(4)}(K_1 - K_2 + K_3 - K_4) \\
&\quad \times \sum_{\mu} \hat{g}_\mu(\{K_n\}) \left( \psi^\dagger(K_1) \sigma_\mu \psi(K_2) \right) \left( \psi^\dagger(K_3) \sigma_\mu \psi(K_4) \right),
\end{align*}
\]

(11)

where $\hat{K}_n = K_n/|\hat{K}_n|$, and we have Taylor expanded $U_{\mu, \nu}(K_1, K_2, K_3, K_4)$ about the loop to obtain the coupling functions $\hat{g}_\mu(\{K_n\})$. Since, $K$ and $\theta$ are physically equivalent, $\hat{g}_\mu(\{K_n\})$ are functions of the loop coordinates only.

| Symmetry | Operation |
|----------|-----------|
| $\theta$-rotation | $R_\theta : \theta \rightarrow \theta + \theta_0$ |
| Pseudospin-$U(1)_c$ | $R_\varphi : \varphi \rightarrow \exp(i \varphi) \psi$ |
| Charge-$U(1)_c$ | $\psi \rightarrow \exp(i \omega_0) \psi$ |
| Mirror plane ($P_K$) | $k_0 \rightarrow -k_0$ and $\psi \rightarrow \sigma_1 \psi$ |
| Antiunitary ($P_{K\bar{K}}$) | $k \rightarrow -k$ and $\psi \rightarrow [i \sigma^2 \sigma_1 \bar{\psi}]$ |
| Antiunitary ($P_{\bar{K}K}$) | $k \rightarrow -k$ and $\psi \rightarrow [\sigma_1 \varphi \bar{\psi}]$ |
| Antiunitary ($P_{K\bar{K}}$) | $k \rightarrow -k$ and $\psi \rightarrow [i \sigma_1 \varphi \psi]$ |
| Antiunitary ($P_{\bar{K}K}$) | $k \rightarrow -k$ and $\psi \rightarrow [\sigma_1 \varphi \psi]$ |
| Generalization | $S_{0,0}$ and $S_{1,0}$ share the same set of symmetries. The Gaussian fixed point described by $S_{\eta=0}$ is invariant under the following choice of scaling, $[\theta], [\varphi] = 0, [k] = 1, [k_0] = \eta, [\psi] = -(\eta + 1)$, where the quantity $X$ scales as $X' = e^{[X]} d'X$ with $d'$ being a logarithmic momentum scale. We note that within our scheme the radius of the loop ($\kappa$) is dimensionless, which implies coarse-graining towards the loop in momentum space [43, 44].

2.2. Interactions
In this section we introduce the vertices describing instantaneous short-range interactions that are consistent with the discrete symmetries of the non-interacting theory. After scaling $k_0$ and $K_{\text{int}}$ as was done for $S_0$, to obtain

\[
\begin{align*}
S_{\text{int}} &= \left( \frac{\psi^\dagger \psi}{\nu_2} \right)^3 \sum_{\mu, \nu = 0}^{4} \int \Delta \left( \prod_{n=1}^{4} d K_n \right) (2\pi)^4 \delta^{(4)}(K_1 - K_2 + K_3 - K_4) \\
&\quad \times \left[ \psi^\dagger(K_1) \sigma_\mu \psi(K_2) \right] \left[ \psi^\dagger(K_3) \sigma_\nu \psi(K_4) \right],
\end{align*}
\]

(10)

where $\int \Delta d K = \int d K f_\mu(\{K_n\}) - \kappa, K_2)$. We assume $U_{\mu, \nu}(\{K_n\}) = U_{\mu, \nu}(\{K_n\})$ to be real valued functions of momentum. In general, there are 16 vertices corresponding to four choices each for $\mu$ and $\nu$. In this paper we focus on only those vertices that are invariant under the discrete symmetries of $S_0$, viz, $P_2$, $P_3$, and $P_4$. The terms that have odd parity under these symmetries are marked with corresponding labels in table 2. From the table we see that only those terms for which $\mu = \nu$ have the same parity as $S_0$. Thus, the minimal set of interactions that respect the discrete symmetries of $S_0$ is given by

\[
\begin{align*}
\hat{S}_{\text{int}} &= \frac{\psi^\dagger \psi}{\nu_2} \int \Delta \left( \prod_{n=1}^{4} d K_n \right) (2\pi)^4 \delta^{(4)}(K_1 - K_2 + K_3 - K_4) \\
&\quad \times \sum_{\mu} \hat{g}_\mu(\{K_n\}) \left( \psi^\dagger(K_1) \sigma_\mu \psi(K_2) \right) \left( \psi^\dagger(K_3) \sigma_\mu \psi(K_4) \right),
\end{align*}
\]

(11)

where $\hat{K}_n = K_n/|\hat{K}_n|$, and we have Taylor expanded $U_{\mu, \nu}(K_1, K_2, K_3, K_4)$ about the loop to obtain the coupling functions $\hat{g}_\mu(\{K_n\})$. Since, $K$ and $\theta$ are physically equivalent, $\hat{g}_\mu(\{K_n\})$ are functions of the loop coordinates only.
Therefore, for $\eta < 2$ ($\eta > 2$) the interactions are irrelevant (relevant) at the Gaussian fixed point. In the presence of irrelevant interactions the Gaussian fixed point is stable and has a finite basin of attraction, whose volume in coupling space is controlled by the parameter $\epsilon = 2 - \eta$. Thus, it is expected that for $\epsilon > 0$ weak short range interactions cannot lead to new phases, and the nodal loop semi-metal is stable. The Weyl-loop semi-metal corresponds to $\epsilon = 1$, where the short-range interactions have bare scaling dimension $-1$, and are strongly irrelevant. Although irrelevant in RG sense, microscopically strong interactions can still drive the system towards a non-trivial phase by pushing the couplings out of the basin of attraction of the Gaussian fixed point. Such finite-coupling instabilities of the $\eta = 1$ ($\epsilon = 1$) system is the focus of this paper. However, at $\eta = 1$ the bare scaling dimension of the couplings are $O(1)$, which obstructs a controlled access to the potential finite-coupling fixed points and instabilities. In order to achieve perturbative control we turn to the limit where $0 \leq \epsilon \ll 1$. In particular, $\epsilon = 0$ corresponds to a Weyl-loop semi-metal with quadratic band-touching. Here the short-range interactions are either marginally relevant or irrelevant, as is the case for Fermi surfaces with unit codimension. Motivated by the smooth interpolation between the quadratic and linear band-touching models at tree level, we analyze the finite coupling instabilities close to $\eta = 2$, using $\epsilon$ as the control parameter. In the spirit of all $\epsilon$ expansions, it is hoped that the small $\epsilon$ analysis would be able to access qualitative elements of the
theory 4. We note that our approach is complementary to reference [45], where the codimension of a one-dimensional Fermi surface was used as a tuning parameter to controllably access a finite coupling pairing instability. Similar strategies based on tuning the dispersion of the dynamical modes [46, 47], and the codimension of the Fermi surface [48–51] have been applied to the study of strongly coupled field theories in the presence of a Fermi surface. Although here we adopt the former strategy, it is possible to utilize the latter approach with the deviation from spatial dimension $d = 2$ as the small parameter.

3. Renormalization group

In this section we outline our RG scheme for understanding the low energy properties of the Weyl-loop semi-metal in the presence of short-range interactions. We will use the Wilsonian RG scheme due to Shankar [43] to derive the beta functions. In particular, we coarse-grain towards the nodal loop by eliminating modes that lie in the region $[\Lambda, \Lambda - \delta \Lambda]$, where $\delta \Lambda \ll \Lambda$, as shown in figure 2. The chemical potential remains unrenormalized, i.e. at perfect compensation, since the Hartree and Fock diagrams in figure 3 vanish due to $\int_\Lambda dK \, \mathcal{G}(K) = 0$. In the rest of this section we focus on the renormalizations to the quartic vertices.

The combination of the UV cutoff imposed by $f_{\infty}(k_r, k_z)$ in equation (13), and conservation of momentum at the quartic vertices on the plane of the loop imposes strong kinematic constrains on most scattering channels [43]. Thus, instead of studying the complicated RG flow of entire coupling functions, we focus on the dominant scattering channels, which are identified by applying the kinematic constrains. There are three scattering channels that dominate the low energy dynamics,

- Pairing (BCS): $g_i(\{\vec{K}_i\}) \rightarrow g_i(\vec{K}_1, \vec{K}_2, -\vec{K}_i, -\vec{K}_3) \equiv N^{-2}V_i(\vec{K}_1, \vec{K}_2),$
- Small angle forward scattering (FS): $g_i(\{\vec{K}_i\}) \rightarrow g_i(\vec{K}_1, \vec{K}_2, \vec{K}_3, \vec{K}_3) \equiv N^{-2}U_i^{(FS)}(\vec{K}_1, \vec{K}_3),$
- Large angle forward scattering (ES): $g_i(\{\vec{K}_i\}) \rightarrow g_i(\vec{K}_1, \vec{K}_2, \vec{K}_3, \vec{K}_3) \equiv N^{-2}U_i^{(ES)}(\vec{K}_1, \vec{K}_3).$

Tuning $\eta$ away from integer values introduces non-locality in the fermion dispersion, because dispersions with non-integer $\eta$ cannot be represented by local operators in coordinate space. Since perturbative RG generates only local terms, notwithstanding logarithms, non-local vertices remain unrenormalized. Although this artifact affects the estimates for a subset of critical exponents, one-loop vertex corrections are not expected to be affected.

---

$\eta = 1$ theory $^4$. We note that our approach is complementary to reference [45], where the codimension of a one-dimensional Fermi surface was used as a tuning parameter to controllably access a finite coupling pairing instability. Similar strategies based on tuning the dispersion of the dynamical modes [46, 47], and the codimension of the Fermi surface [48–51] have been applied to the study of strongly coupled field theories in the presence of a Fermi surface. Although here we adopt the former strategy, it is possible to utilize the latter approach with the deviation from spatial dimension $d = 2$ as the small parameter.

---

$^4$ Tuning $\eta$ away from integer values introduces non-locality in the fermion dispersion, because dispersions with non-integer $\eta$ cannot be represented by local operators in coordinate space. Since perturbative RG generates only local terms, notwithstanding logarithms, non-local vertices remain unrenormalized. Although this artifact affects the estimates for a subset of critical exponents, one-loop vertex corrections are not expected to be affected.
Since $g_{\alpha}(\{\vec{K}_i\})$ are dimensionful for $\eta = 2$, we have expressed the scaling dimension of $g_{\alpha}(\{\vec{K}_i\})$ in units of $\Lambda$, such that $V_\alpha$, $U_\alpha^{(\text{FS})}$, and $U_\alpha^{(\text{ES})}$ are dimensionless. Since there are 4 types of interactions in equation (13), the three channels generate 12 coupling functions. However, the FS and ES couplings are not truly distinct due to non-conservation of pseudo-spin, and the interactions in the non-BCS, i.e. forward scattering, channel can be represented either in terms of ES or FS couplings. Here we adopt the FS representation, such that there are only eight independent coupling functions — four each for the BCS channel and the FS channel. As we will show below, the RG flow in the eight dimensional coupling space is further simplified by the fact that, at one-loop order, the flow of the BCS couplings are decoupled from the flow of the FS couplings to the leading order in $\Lambda/\kappa \ll 1$. Additionally, owing to the $\theta$-rotation symmetry, the one-loop RG flow remains diagonal in the angular-momentum basis with identical flow for each harmonic. This eliminates the complications arising from the functional nature of the couplings, since one may separately analyze the flow of coupling constants in a particular angular momentum channel, without worrying about coupling between different channels.

We note that this simplification is a consequence of the $\theta$-rotational symmetry. In the absence of $\theta$-rotation, for a model with one coupling function, it is still possible to diagonalize the RG flow by a suitable choice of basis [52]. However, such a diagonalization is generally not possible for a system with multiple coupling functions that mix under RG flow.

Because of its generic importance in the presence of extended zero-energy manifold in fermionic systems, we will first focus on the BCS channel, and then discuss the forward scattering channel in section 5 where exciton condensates arise. In both sections 4 and 5 we derive the one-loop RG flow for the respective couplings, show their fixed point structure, and determine the trajectories of the RG flow towards strong-coupling. We also identify the nature of the states that are realized at strong-coupling by tuning a single parameter. These states may be considered as finite coupling instabilities of the Weyl-loop semi-metal.

4. RG analysis of BCS couplings

In this section we analyze the RG flow of the BCS couplings which are identified through the following kinematic constraint on the interaction vertices of the action,

$$S_{\text{int}}^{(\text{BCS})} = N^{-2} \int dK \frac{d}{dK} (2\pi)^4 \delta^4(K - K_2 - K_3 - K_4) \delta(\vec{K}_1 + \vec{K}_3) \delta(\vec{K}_2 + \vec{K}_4)$$

$$\times \left[ \frac{V_1(\vec{K}_1, \vec{K}_2)}{\kappa} \left( \bar{\psi}(K_1) \gamma_0 \psi(K_2) \right) \left( \bar{\psi}(K_3) \gamma_0 \psi(K_4) \right) \right.$$

$$- \left. \frac{V_2(\vec{K}_1, \vec{K}_2)}{\kappa} \left\{ (\bar{\psi}(K_1) \gamma_1 \psi(K_2) \right) \left( \bar{\psi}(K_3) \gamma_1 \psi(K_4) \right) + (\gamma_1 \rightarrow \gamma_2) \right\} \right]$$

$$- \left. \frac{V_3(\vec{K}_1, \vec{K}_2)}{\kappa} \left\{ (\bar{\psi}(K_1) \gamma_2 \psi(K_2) \right) \left( \bar{\psi}(K_3) \gamma_2 \psi(K_4) \right) \right.$$

$$- (\gamma_1 \rightarrow \gamma_2) \left. \right\} + \left. \frac{V_4(\vec{K}_1, \vec{K}_2)}{\kappa} \left\{ (\bar{\psi}(K_1) \psi(K_2) \right) \left( \bar{\psi}(K_3) \psi(K_4) \right) \right.$$

$$\left. \right\} \right].$$

(17)

Here $\vec{K}_i$ is the unit vector along $K_i$. Imposing the rotational invariance under the action of $R_\kappa$, constrains the functional form of $V_1(\vec{K}_1, \vec{K}_2) \rightarrow V_1(\theta_1 - \theta_2)$, where $\theta_i$ are the angular positions on the loop and are physically equivalent to $\vec{K}_i$. We note that the two dimensional unit vector $\vec{K}_i$ is the projection of the three dimensional unit vector $\vec{K}_i$ on the plane of the loop; the dependence of $V_1$ on the third component of $\vec{K}_i$ is irrelevant. As we will show, different angular momentum channels further decouple, so that one may work with sets of coupling constants in a particular angular momentum channel. Additionally, the action $S_{\text{int}}^{(\text{BCS})} + S_{\text{int}}^{(\text{ES})}$ with $V_{2+} = 0$ is invariant under $R_\kappa$ for $\xi(\theta) = \text{sgn}(\theta) \xi$ with $\xi \in (-\pi, \pi]$. Since the symmetry involves a quasi-global choice of $\xi(\theta)$, it is a subgroup of the pseudospin--$U(1)$ symmetry, and we refer to it as BCS--$U(1)$ symmetry. The BCS--$U(1)$ symmetry ensures that $V_{2+}$ vertex is not generated by scatterings in the BCS channel, if it is absent at tree level.

There are four diagrams at one-loop order as shown in figure 4. The contribution from the BCS diagram is enhanced by a factor of $1/\kappa$ with respect to the other three diagrams. This underscores the fact that the FS couplings do not mix with the BCS couplings at leading order in $\Lambda/\kappa$. We note further that the BCS diagram has a log divergence at $\epsilon = 0$ which makes the problem suitable for a RG analysis. While the analysis here is developed for the undoped material, this log divergence persists even at non-zero doping (whereupon it becomes just the familiar Cooper log). The situation in the doped case was discussed in [42] and is not discussed further here.
The quantum correction due to the BCS diagram, $\delta S^{\text{BCS}}$, is calculated in appendix A. After adding $\delta S^{\text{BCS}}$ to $S^{\text{int}}_{\text{BCS}}$, we rescale the dimensionful quantities to restore the UV cutoff to $\Lambda$. By comparing this renormalized action with the classical (tree level) action we obtain the RG flow equations for the BCS couplings at the leading order in $\Lambda/\kappa$,

$$
\frac{\partial}{\partial \epsilon} V_{1;1} = -V_{1;1} \left[ (2 - \eta) + \frac{1}{4\pi} (V_{1;1} + 2V_{2;-1}) \right] - \frac{1}{4\pi} (V_{1;3}^2 + 2V_{2;+1}^2 + 2V_{2;-1}^2 + 2V_{3;1}V_{2;-1}) 
$$

$$
\frac{\partial}{\partial \epsilon} V_{2;+1} = -V_{2;+1} \left[ (2 - \eta) + \frac{1}{2\pi} (V_{1;1} - V_{3;1}) \right],
$$

$$
\frac{\partial}{\partial \epsilon} V_{2;-1} = -(2 - \eta) V_{2;-1} - \frac{1}{8\pi} (2V_{2;-1} + V_{1;1} + V_{3;1})^2,
$$

$$
\frac{\partial}{\partial \epsilon} V_{3;1} = -V_{3;1} \left[ (2 - \eta) + \frac{1}{2\pi} (V_{1;1} + V_{2;-1}) \right] + \frac{1}{2\pi} (V_{2;+1}^2 - V_{2;-1}^2 - V_{1;1}V_{2;-1}).
$$

Here $V_{n;J}$ represents the $J$-th angular momentum harmonic of $V_{n}(\theta)$. Since $\partial_{\epsilon} V_{2;+1} \propto -V_{2;+1}$, if bare $V_{2;+1} = 0$, then it is not generated during the course of the RG flow.

**4.1. Fixed points**

The expressions of the beta-functions are simplified by changing coordinates in the coupling space as

$$
f_{1;+1} = V_{2;+1} \mp \frac{1}{2} (V_{1;1} - V_{3;1}), \quad f_{2;+1} = V_{2;-1} \pm \frac{1}{2} (V_{1;1} + V_{3;1}).
$$

The flows of $f_{n;\pm;J}$ for $\eta = 2 - \epsilon < 2$ are governed by

$$
\frac{\partial}{\partial \epsilon} f_{1;+1} = -f_{1;+1} \left[ \epsilon + \frac{1}{2\pi} f_{1;+1} \right],
$$

$$
\frac{\partial}{\partial \epsilon} f_{1;-1} = -f_{1;-1} \left[ \epsilon - \frac{1}{2\pi} f_{1;-1} \right],
$$

$$
\frac{\partial}{\partial \epsilon} f_{2;+1} = -f_{2;+1} \left[ \epsilon + \frac{1}{2\pi} f_{2;+1} \right],
$$

$$
\frac{\partial}{\partial \epsilon} f_{2;-1} = -f_{2;-1}.
$$

The beta-functions imply that $f_{n;\pm;J}$ do not mix at one-loop order. We plot the projections of the four dimensional RG flow on the $(f_{1;+1}, f_{1;-1})$ and $(f_{2;+1}, f_{2;-1})$ planes in figure 5. The fixed points are derived from the conditions for simultaneous vanishing of the four beta functions, which result in 3 quadratic and 1 linear equations that have $2^3$ solutions. The Gaussian fixed point is the only stable fixed point of the RG flow. It has a finite basin of attraction, whose volume is controlled by $\epsilon$. The non-Gaussian fixed points have at least one relevant direction which take(s) the flow towards the Gaussian fixed point or strong-coupling, depending on which side of the separatrices the couplings lie. In table 3 we list all non-Gaussian fixed points according to the number of relevant directions they possess.

In order to interpret the fixed points in terms of the original couplings of the model we invert the relations in equation (22) to obtain
From table 3 we note that at $\text{III}_{\text{BCS}}$ $V_{2+1}$ vanishes, which implies the emergence of the BCS-$U(1)$ symmetry at the critical fixed point. The BCS-$U(1)$ symmetry is also present at the bi- and tri-critical fixed points $\text{IV}_{\text{BCS}}$ and $\text{VII}_{\text{BCS}}$, respectively. For the rest of this section we focus on the subspace where $V_{2+1} = 0$, i.e. the subspace invariant under BCS-$U(1)$.

To motivate this approximation, note that it is natural to take the bare UV scale interaction to be pure density-density, without any pseudospin structure. An interacting theory with only

\begin{align}
V_{2+1} &= \frac{1}{2}((-f_{2+1} - f_{2-1}) + (f_{1+1} - f_{1-1})), \\
V_{2-1} &= \frac{1}{2}((f_{2+1} + f_{1-1})), \\
V_{2-1} &= \frac{1}{2}((f_{2+1} + f_{1-1})), \\
V_{2-1} &= \frac{1}{2}((-f_{2+1} - f_{2-1}) - (f_{1+1} - f_{1-1})) .
\end{align} 

(27)
density-density interactions will have this BCS-U(1) symmetry. Interactions with non-trivial pseudospin structure will then be generated under the RG, but only those interactions that lie within the 'maximally symmetric subspace.' In particular, $V_{2±}$, which breaks the BCS-U(1) symmetry, will not be generated. Additionally of course, restricting to the maximally symmetric subspace has the advantage of providing us with a 'toy model' that is more amenable to analysis.

We therefore restrict ourselves to the subspace with $V_{2±} = 0$. Since $V_{2±}$ was a relevant perturbation at $V_{5±}$ and $V_{II}$, these fixed points become critical and bicritical, respectively, with respect to BCS-U(1) invariant perturbations. Thus, we obtain one Gaussian, two critical, and one bi-critical fixed points. The non-Gaussian fixed points are listed in table 4 in terms of $V_{2±}$.

Since both $III_{BCS}$ and $IV_{BCS}$ are critical fixed points, they potentially separate the non-interacting Gaussian fixed point (Weyl-loop semi-metal phase) from superconducting phases. We first discuss the stability of $III_{BCS}$, and then apply the same analysis to $IV_{BCS}$. Since the RG flow of $f_{2±}$ mutually decouple and they are irrelevant when $|f_{2±}| < \epsilon$, the critical fixed point $III_{BCS}$ which is realized at $f_{2±} = 0$, can only be destabilized by perturbations with non-zero component along $f_{2±}$. As depicted in figure 5(b), the sign of the deviation $\delta f_{2±} = f_{2±} - f_{2±}^*$ determines whether the perturbation takes the flow towards the Gaussian fixed point or towards strong coupling where $f_{2±}$ is large and negative.

In contrast to $III_{BCS}$, $IV_{BCS}$ is located on the $(f_{1±}, f_{2±})$ plane with $f_{2±} = 0$. Since in the $V_{2±} = 0$ subspace $f_{1±} = f_{1±}$ are equivalent, the RG flow in the neighborhood of $IV_{BCS}$ is governed by

$$\partial_\tau \delta f_{1±} = \epsilon \delta f_{1±}, \quad \partial_\tau \delta f_{2±} = - \epsilon \delta f_{2±}.$$  

Therefore, perturbations with $\delta f_{2±} \approx 0$ are relevant and, depending on its sign, take the flow either towards the Gaussian fixed point, or towards strong coupling where $f_{2±}$ is large and positive.

### 4.2. Flow to strong coupling

In this subsection we identify the effective interactions along the stable RG flow trajectory that takes the theory towards strong coupling, as we tune away from the critical fixed points. As in the preceding subsection, we discuss the flow away from $III_{BCS}$ first, followed by $IV_{BCS}$.

Let us label the flow away from the critical point towards strong coupling on the $f_{2±}$ axis as a strong coupling trajectory (SCT). Due to the stability of the Gaussian fixed point in the $(f_{1±}, f_{1±}, f_{2±})$ subspace, the SCT is stable against perturbations perpendicular to it. With the aid of equation (27) we note that on the SCT $V_{1±} = V_{2±} = V_{3±} = 0 \approx f_{2±} < -\frac{1}{\epsilon}$. Thus, the BCS vertices on the SCT are given by

| Table 3. Non-Gaussian fixed points in units of $\pi \tau$ for the BCS couplings, with at least one relevant direction. The number of relevant couplings required to be tuned to achieve the criticality determines its order, viz. stable (0), critical (1), bicritical (2), and tricritical (3), where the numbers within the parentheses are the number of relevant couplings. Thus, fixed points $I_{BCS}$, $II_{BCS}$, $III_{BCS}$, $IV_{BCS}$, $V_{BCS}$, $VI_{BCS}$, and $VII_{BCS}$ are critical, and $VIII_{BCS}$ is tricritical. |
| --- |
| $###$ | $f_{2±}$<sup>1</sup> | $f_{2±}$<sup>2</sup> | $f_{2±}$<sup>3</sup> | Tune |
| $I_{BCS}$ | $-2$ | $0$ | $0$ | $f_{2±}$ |
| $II_{BCS}$ | $0$ | $2$ | $0$ | $f_{2±}$ |
| $III_{BCS}$ | $0$ | $-1$ | $0$ | $f_{2±}$ |
| $IV_{BCS}$ | $-2$ | $2$ | $0$ | $f_{2±}$ |
| $V_{BCS}$ | $-2$ | $0$ | $-1$ | $f_{2±}^*$ |
| $VI_{BCS}$ | $0$ | $2$ | $-1$ | $f_{2±}^*$ |
| $VII_{BCS}$ | $-2$ | $2$ | $-1$ | $f_{2±}^*$ |

| Table 4. The fixed points (in units of $\pi \tau$) in table 3 that lie in the $V_{2±} = 0$ subspace. The first two are critical fixed points, while the last one is bicritical. |
| --- |
| $###$ | $V_{3±}$ | $V_{2±}$ | $V_{4±}$ | Tune |
| $III_{BCS}$ | $-1/2$ | $-1/2$ | $-1/2$ | $f_{2±}^*$ |
| $IV_{BCS}$ | $-2$ | $0$ | $2$ | $(V_{1±} - V_{3±})$ |
| $VII_{BCS}$ | $-5/2$ | $-1/2$ | $3/2$ | $(V_{1±} - V_{3±}), f_{2±}^*$ |
where we have suppressed the momentum dependence of the fields. On the plane of the Weyl-loop the vertices simplify to

\[ L_{III}^{\text{(BCS)}}(\{K_i\}) = \frac{1}{\kappa} V_i(\tilde{K}_i, \tilde{K}_2) [\bar{\psi} \gamma_0 \psi]^2 + (\bar{\psi} \gamma^\dagger \psi)^2 - (\bar{\psi} \gamma_2 \psi)^2], \tag{29} \]

where \( \kappa \) is the coupling constant. On the plane of the Weyl-loop the vertices simplify to

\[ L_{III}^{\text{(BCS)}}(\tilde{K}_i, \tilde{K}_2) = \frac{1}{2\kappa} V_i(\tilde{K}_i, \tilde{K}_2) [\bar{\psi} \gamma_0 \psi]^2 + (\bar{\psi} \gamma^\dagger \psi)^2 - (\bar{\psi} \gamma_2 \psi)^2]. \tag{30} \]

Since \( V_1 < 0 \) on the SCT, this indicates that a pairing instability is driven by the condensation of \( \bar{\psi} (\tilde{K}_i) \psi(\tilde{K}_j) \).

The SCT originating at \( V_{\text{BCS}} \) is defined by \( V_{\text{BCS}} = (f_{-1,1}, 0, f_{-1,1}) \). Therefore, along the SCT the BCS vertices with momenta on the plane of the Weyl-loop simplifies to

\[ L_{III}^{\text{(BCS)}}(\tilde{K}_i, \tilde{K}_2) = V_i(\tilde{K}_i, \tilde{K}_2) [\bar{\psi} \gamma_0 \psi]^2 + (\bar{\psi} \gamma^\dagger \psi)^2 - (\bar{\psi} \gamma_2 \psi)^2]. \tag{31} \]

Since \( V_1 < 0 \) along the SCT, both vertices in equation (31) can drive a pairing instability. In the following subsection we verify the identity of the superconducting states indicated above through explicit computation of the anomalous scaling dimension of various pairing susceptibilities along the two SCTs.

### 4.3. Symmetry broken states

In this subsection we determine the nature of the superconducting states that arise as instabilities of the critical points in the \( V_{2+0} = 0 \) subspace. In particular, we compute the change of scaling dimension of the pairing susceptibilities along the SCT as the system flows towards strong-coupling.

We consider insertions of fermion pairs,

\[ S_2^{(\mu)} = \int dK \, \Delta_\mu(\tilde{K}) \bar{\Psi} (\tilde{K}) \gamma_\mu \Psi(K) + \text{h.c.}, \tag{32} \]

where \( \mu = 0, 1, 2, 3 \). The pairing amplitude \( \Delta_\mu(\tilde{K}) \gamma_\mu = -\Delta_\mu(\tilde{K}) \gamma^\dagger_\mu \), with \( \Delta_\mu(\tilde{K}) \) being a complex valued function. The 'singlet' pairing corresponds to \( \gamma_\mu = -\gamma^\dagger_\mu \) and \( \Delta_\mu(\tilde{K}) = \Delta_\mu(\tilde{K}), \) while for \( \gamma_\mu = \gamma^\dagger_\mu \) and \( \Delta_\mu(\tilde{K}) = -\Delta_\mu(\tilde{K}) \) the pairing occurs in a 'triplet' channel. At one-loop order \( \Delta_\mu(\tilde{K}) \) is renormalized by the RG flow of each angular momentum harmonic of \( \Delta_\mu(\tilde{K}) \) is governed by

\[ \partial_\tau \Delta_{i,\mu} = \Delta_{i,\mu}[2 + \delta_\mu(\{V_{\text{BCS}}\})], \tag{33} \]

where the anomalous dimension of \( \Delta_{i,\mu} \), \( \delta_\mu(\{V_{\text{BCS}}\}) \), is defined in equation (B6).

Along the SCT originating from \( V_{\text{BCS}} \), the susceptibility for \( \gamma_3 \) is most strongly enhanced, and the RG flow of \( \Delta_3(\tilde{K}) \) is governed by

\[ \partial_\tau \Delta_{3,\mu} = \Delta_{3,\mu}[2 - \frac{V_{i,\mu}}{\pi}], \tag{34} \]

where we have used the fact that along the SCT \( V_{i,\mu} = V_{3,\mu} = V_{2-\mu} = \frac{1}{2} f_{2,\mu} \). Since \( V_{i,\mu} < 0 \), \( \Delta_3(\tilde{K}) \) obtains a positive anomalous dimension. The scaling dimensions of \( \Delta_3(\tilde{K}) \) for \( \mu = 3 \) do not change because \( \delta_\mu(\{V_{\text{BCS}}\}) = 0 \).

From the symmetry properties of the gap function, we obtain \( \Delta_3(\tilde{K}) = -\Delta_3(\tilde{K}) \), which is equivalent to \( \Delta_3(\theta + \pi) = -\Delta_3(\theta) \) in terms of the loop coordinate \( \theta \). Decomposing \( \Delta_3(\theta) \) in terms of angular momentum harmonics,

\[ \Delta_3(\theta) = \sum_{J=-\infty}^{\infty} e^{-i\theta J} \Delta_{3,J}, \tag{35} \]
we note that only the odd $f$ harmonics are non-zero. While the flow equations in different odd angular momentum channels are identical, the degeneracy between different angular momentum channels will be broken by the initial conditions. The largest ‘bare interaction’ is likely to arise in the lowest allowed angular momentum channel (i.e. $f = \pm 1$) which will then be the leading instability. Therefore, the leading instability is expected to be ‘p-wave’ consistent with general arguments \cite{42}. Retaining only the $f = \pm 1$ harmonic we express

$$\Delta_f(\theta) = \tilde{\Delta}_+ \cos \theta + i \tilde{\Delta}_- \sin \theta,$$

where the constants $\tilde{\Delta}_\pm = 2(\Delta_{3,-1} \pm \Delta_{3,1})$. Allowing for weak radial momentum dependence on the plane of the loop we generalize $\Delta_f(\theta)$ to

$$\Delta_f(\vec{K}) = \tilde{\Delta}_+ \frac{K_x}{\kappa} + i \tilde{\Delta}_- \frac{K_y}{\kappa}.$$  

In terms of the generalized expression for a superconducting order parameter

$$\tilde{\Delta}(\vec{K}) = i(d_0(\vec{K}) + d(\vec{K}) \cdot \sigma)\sigma_2,$$

the current state corresponds to $d_0(\vec{K})$, $d_1(\vec{K})$, $d_2(\vec{K}) = 0$, and $d_3(\vec{K}) = -i\Delta_3(\vec{K})$.

Note that we have two degenerate channels $f = \pm 1$ which are related by time reversal symmetry. We now discuss the competition of these two channels below $T_c$. For the superconducting state where $f = \pm 1$ components are in-phase ($\Delta_{3,1} = \Delta_{3,-1}$) and out-of-phase ($\Delta_{3,1} = -\Delta_{3,-1}$), $(\Delta_+, \Delta_-) = (4\Delta_{3,-1}, 0)$ and $(\Delta_-, \Delta_+) = (0, 4\Delta_{3,-1})$, respectively. Therefore, in this state the gap function vanishes at two points on the Fermi surface — this is nodal superconductivity which spontaneously breaks rotation symmetry. In contrast if only one out of the $f_\sigma$ channels develops a non-zero order parameter this corresponds to

$$\Delta_f(\vec{K}) = \begin{cases} 2\Delta_{3,-1} \frac{K_x}{\kappa} (K_x + iK_y) & \text{for } f = -1 \\
2\Delta_{3,1} \frac{K_x}{\kappa} (K_x - iK_y) & \text{for } f = +1. \end{cases}$$

This type of ordering spontaneously breaks time reversal symmetry and corresponds to chiral superconductivity. Note that these gap functions do not vanish on the Fermi surface, and thus are expected to have a larger condensation energy. We show this explicitly by minimizing the Ginzburg-Landau free energy, similar to \cite{53,54,55,56,57}.

Since $V_i < 0$ along the SCT, we introduce an auxiliary field, $\phi(\vec{k})$, to decompose the first term in equation \eqref{30}. Integrating out the fermions generates an effective Ginzburg–Landau action for $\phi(\vec{k})$. In the symmetry broken state below the critical temperature we ignore spatiotemporal fluctuations of $\phi(\vec{k})$, and focus on the ‘potential’ part of the effective action. We ignore contributions from scattering between Cooper pairs at different parts of the loop, and express the total free energy as a sum over free energy per unit length of the loop,

$$\mathcal{F} = \int \frac{d\theta}{2\pi} \mathcal{F}(\theta) = \int \frac{d\theta}{2\pi} \frac{a}{2} |\phi(\theta)|^2 + |b\phi(\theta)|^4,$$

where $a$ and $b$ are effective parameters. Substituting $\phi(\theta) = \Delta_f(\theta)$ (defined in equation \eqref{36}) leads to

$$\mathcal{F} = \frac{a}{2} (|\Delta_+|^2 + |\Delta_-|^2) + \frac{3b}{8} (|\Delta_+|^4 + |\Delta_-|^4) + \frac{b}{4} |\Delta_+|^2 |\Delta_-|^2 \left( 1 - \frac{1}{2} \left( \frac{\Delta_+^* \Delta_-}{|\Delta_+||\Delta_-|} - c.c. \right) \right)^2.$$  

We note that the third term represents a repulsion between the two components of $\Delta_f(\theta)$. For a condensate to form the condensation energy needs to overcome the energy barrier due to the repulsion. Since in the superconducting phase $a < 0$ and $b > 0$, the configuration that minimizes $\mathcal{F}$ is determined by the relative magnitude of $|a|$ and $b$. By expressing $(\Delta_+, \Delta_-) = \Delta_+(1 - \gamma e^{3i\theta})$, in units of $b|\Delta_+|^4$ (or equivalently $b|\Delta_-|^4$) we obtain

$$\frac{2\mathcal{F}}{b|\Delta_+|^4} = -\frac{|a|}{b|\Delta_+|^2} (1 + x) + \frac{3}{4} \frac{a}{b} (1 - x)^2 + 2x \left( 1 + \frac{1}{2} \sin^2 A \right).$$

Minimization of the scaled free energy with respect to the relative magnitude $x$ and the relative phase $A$ leads to three possible states corresponding to $x = 0$, $(x > 0, A = \pi/2)$ or $(3\pi/2)$, and $(x > 0, A = 0$ or $\pi)$ as long as $|\Delta_+|^2 > 1/2$. The conditional inequality is selfconsistently satisfied by $|\Delta_+|$ at each minimum. The first two minima correspond to nodal states, while the last one is a pair of nodeless states which are equivalent to those in equation \eqref{39} for $x = 1$. The lower bound on the dimensionless ratio $\frac{|a|}{b|\Delta_+|^2}$ originates from the competition between the repulsion and condensation energy. By comparing the free energy at these minima we conclude that the nodeless state is realized at the global minimum of the free energy. Thus the leading instability associated with the flow to strong coupling emerging from the III$_{BSCS}$ vertex is to a fully gapped chiral state with odd
angular momentum and with $\Delta(\vec{k})$ proportional to the unit matrix in pseudospin space (i.e. $d_0 = d_3 = 0$). Further, we note that this is the only state that involves solely intra-band pairing, and is smoothly connected to paired states in both the conduction and valence band. Thus this state is expected to be most robust to chemical potential disorder \cite{42}. Indeed, it may even be enhanced by disorder through the mechanism discussed in \cite{58–60}.

Applying the above analysis to the SCT originating from IV\(_\text{BCS}\), we find that pairing susceptibilities for $\gamma_1$ and $\gamma_2$ vertices are enhanced identically, while $\gamma_0$ and $\gamma_3$ are unaffected. From the symmetry of $\Delta_0, \Delta_2$, we identify the $\gamma_1$ ($\gamma_2$) pairing vertex as a singlet (triplet). The triplet pairing is distinguished from the one associated with III\(_\text{BCS}\) with the aid of equation (38), and it corresponds to $d_{\mu=3}(\vec{k}) = 0$ and $d_0(\vec{k}) = \Delta_0(\vec{k})$. The singlet corresponds to $d(\vec{k}) = 0$ and $d_0(\vec{k}) = -i\Delta_0(\vec{k})$. While the quantum scaling dimensions of the singlet and triplet pairings are identical due to the BCS- $U(1)$ symmetry, the pairings occur in distinct angular momentum channels: the singlet (triplet) pairing occurs in even (odd) angular momentum channel. Since there is no reason why the bare couplings (which set the initial conditions for the RG flow) should be equal in distinct angular momentum channels, the apparent degeneracy will thus be broken by the initial conditions, and the leading instability will occur in the channel $d_{\mu=3}(\vec{k}) = 0$ and $d_0(\vec{k}) = \Delta_0(\vec{k})$ if the most attractive bare coupling is an odd angular momentum channel, and in the channel $d(\vec{k}) = 0$ and $d_0(\vec{k}) = -i\Delta_0(\vec{k})$ if the most attractive bare coupling is in an even angular momentum channel. In the case where the leading instability is in a channel with non-zero $J$, the $\pm J$ channels will again be degenerate, and one may have either fully gapped chiral superconductors or gapless non-chiral superconductors. An analysis of the most likely symmetry broken state resulting from the instability driven by the $\gamma_2$ pairing vertex indicates a fully gapped $p$-wave state as obtained above. However, it is distinguished from the same through the nontrivial matrix structure of the order parameter in the pseudospin space since $d_3 \neq 0$. The most likely candidate for the symmetry broken state for the singlet pairing is a uniform $s$-wave superconductor. We note that these states involve interband pairing \cite{42} and thus will likely be rapidly disrupted by chemical potential disorder, unlike the state arising from the flow out of III\(_\text{BCS}\).

5. RG analysis of forward scattering channel

In this section we discuss the RG flow of the forward scattering channel. In the absence of nesting, condensation of intra-orbital particle-hole pairs carrying a finite momentum is suppressed by a lack of density of states. Consequently, additional fine tuning is necessary to drive such a phase transition. Thus in a single-orbital system the forward scattering channel does not lead to a weak coupling instability of the metallic state \cite{43}. However, in multi-orbital systems additional forward scatterings between different orbitals are present, which can lead to the condensation of inter-orbital particle-hole pairs which carry zero net momentum. In the presence of a Fermi surface or nodal lines, the zero-momentum pairing of electrons and holes can utilize the extended manifold of degenerate states available at the Fermi level to enhance their condensation energy. Another way to say this is to note that there is a log divergence in the forward scattering channel for the undoped Weyl loop system (at $q = 2$) which can lead to an excitonic instability. Since the exciton condensation crucially depends on the degeneracy of the two bands, this log divergence is cut off by doping and there is no weak coupling instability for the torus Fermi surface. However our focus here is on the possible symmetry broken phases resulting from instabilities driven by forward scatterings in the undoped system.

As noted earlier, there are two equivalent ways of representing the interaction vertices for the forward scattering channel. Here we have adopted the FS representation, and express the vertices as

\[
S^{(\text{FS})}_{\text{int}} = \frac{\alpha^{n-2}}{\Lambda} \int_{\Lambda} \prod_{n=1}^{4} dK_n \left(2\pi \right)^4 \delta^{(4)}(K_1 - K_2 + K_3 - K_4) \delta(\bar{K}_1 - \bar{K}_2) \delta(\bar{K}_3 - \bar{K}_4) \times \frac{U_i(\bar{K}_1, \bar{K}_2)}{\kappa} \left[ \bar{\psi}(K_1)\gamma_0 \psi(K_2) \right] \left[ \bar{\psi}(K_3)\gamma_0 \psi(K_4) \right],
\]

\[
= \frac{U_{2+}(\bar{K}_1, \bar{K}_2)}{\kappa} \left[ \bar{\psi}(K_1)\gamma_1 \psi(K_2) \right] \left[ \bar{\psi}(K_3)\gamma_1 \psi(K_4) \right] + (\gamma_1 \rightarrow \gamma_2) \]

\[
= \frac{U_{2-}(\bar{K}_1, \bar{K}_2)}{\kappa} \left[ \bar{\psi}(K_1)\gamma_1 \psi(K_2) \right] \left[ \bar{\psi}(K_3)\gamma_1 \psi(K_4) \right] - (\gamma_1 \rightarrow \gamma_2) \]

\[
+ \frac{U_{3}(\bar{K}_1, \bar{K}_3)}{\kappa} \left[ \bar{\psi}(K_1)\gamma_3 \psi(K_2) \right] \left[ \bar{\psi}(K_3)\gamma_3 \psi(K_4) \right],
\]

where $U_j(\bar{K}_1, \bar{K}_2) \equiv U_j(\theta_1 - \theta_2)$, and we have dropped explicit reference to the representation for the coupling functions. Due to the kinematic restriction, the charge- $U(1)$ symmetry is present in the forward scattering
sector. Indeed $S_{U|y} + S_{int}^{(FS)}$ resembles the Fermi liquid fixed point. Although $R_Z$ is not a symmetry of $S_{int}^{(FS)}$ for any non-trivial choice of $\xi(\theta)$, it becomes a symmetry when $U_{2-} = 0$ with $\xi(\theta) = \xi$. In order to contrast a similar symmetry present in the BCS sector, we refer to the current one as the FS-$U(1)$ symmetry. The RG flow in the $U_{2-} = 0$ subspace is protected by the FS-$U(1)$ symmetry, which implies that $\partial_r U_{2-} \propto U_{2-}$.

### 5.1. Fixed points

In the forward scattering channel, even at zero energy, the net incoming momentum is generically non-zero as the momenta of typical incoming states are not anti-parallel in $K$-space. In order to transfer the finite momentum of the incoming states to the outgoing states, the virtual excitations must carry a net momentum. Therefore, scattering processes that favor virtual excitations with zero net momentum are suppressed for forward scattering channels at low energy, as is the case for the BCS diagram. The internal loop in the other three diagrams in figure 4 carry a net momentum, and renormalizes $U_I$ at leading order in $\Lambda/\kappa$. The FS couplings flow according to

$$\partial_r U_{1,1} = -\epsilon U_{1,1},$$

$$\partial_r U_{2+,1} = -U_{2+,1} \left[ \epsilon + \frac{2}{\pi} U_{2-;1} \right] - \frac{2}{\pi} U_{2-;1}^2,$$

$$\partial_r U_{2-,1} = -U_{2-,1} \left[ \epsilon + \frac{4}{\pi} U_{2-,1} \right],$$

$$\partial_r U_{3,1} = -U_{3,1} \left[ \epsilon + \frac{4}{\pi} U_{3,1} \right].$$

It is interesting to note that when all four couplings are repulsive, they are irrelevant. Moreover, the $U_1$ vertex which mediates scatterings between total densities in momentum space, $\sum_{i=1,2} c_i^\dagger (K) c_i (K)$, remains unrenormalized.

There are $2^3$ solutions to $\partial_r U_{1,1} = 0$, which correspond to distinct combinations of the fixed points of $U_{1,1}$. The non-Gaussian fixed points are listed in table 5. There are 3 critical, 3 bicritical, and 1 tricritical fixed points in the four dimensional coupling space. Among the critical fixed points, the FS-$U(1)$ symmetry emerges at $I_{FS}$ due to the vanishing of $U_{2-;1}$. Since it is protected by an emergent symmetry, in the rest of the section we focus on the $U_{2-;1} = 0$ subspace. Two more interacting fixed points are present in the subspace, both of which lose a relevant direction due to the projection to the subspace. Thus, in the $U_{2-;1} = 0$ subspace there are 2 critical ($I_{FS}$, $I_{VFS}$) and 1 bicritical ($VII_{FS}$) fixed points.

The critical points are expected to separate the Weyl-loop semi-metal phase from symmetry broken phases, which are realized by tuning a single parameter. In the $U_{2-;1} = 0$ subspace the two critical points $I_{FS}$ and $I_{VFS}$ are achieved by tuning $U_{3,1}$ and $U_{2+,1}$, respectively. On tuning these coupling beyond their critical values the system is set to flow towards two distinct strong coupling fixed points. In this section we determine the stable RG flow trajectories that lead to those fixed points, which will help us identify the possible symmetry broken states that can be realized at finite (or strong) coupling. We first discuss the SCT originating from $I_{FS}$, followed by $I_{VFS}$.

Since all couplings but $U_{3,1}$ vanish at $I_{FS}$, it is easy to see that the SCT must lie along $U_{3,1} < -\pi \epsilon / 4$. This trajectory is stable against small perturbations since the Gaussian fixed points of $U_{2-;3,1}$ are stable. The effective interaction along the SCT,

$$L_{I}^{(FS)} = \frac{U_{3} (\tilde{K}_0, \tilde{K}_2)}{\kappa} \left( \psi^\dagger (K) \sigma_3 \psi (K) \right) \left( \psi^\dagger (K) \sigma_3 \psi (K) \right),$$

indicates that particle-hole pairs $\psi^\dagger (K) \sigma_3 \psi (K)$ are progressively favored as $U_{3} (\tilde{K}_0, \tilde{K}_2)$ increases. Condensation of $\psi^\dagger (K) \sigma_3 \psi (K)$ produces a mass term for the fermions, which gaps out the fermionic excitations. An identical analysis for the SCT originating at $I_{VFS}$ reveals a stable SCT along $U_{2+,1} < -\pi \epsilon / 2$, and effective interaction

| #   | $U_{1,1}$ | $U_{2+,1}$ | $U_{2-,1}$ | $U_{3,1}$ | Tune            |
|-----|-----------|-----------|------------|-----------|----------------|
| I_{FS} | 0         | 0         | 0          | -1/4      | $U_{3,1}$     |
| II_{FS} | 0         | -1/4      | -1/4       | 0         | $(U_{2+,1} + U_{2-;1})$ |
| III_{FS} | 0        | -1/4      | 1/4        | 0         | $(U_{2+,1} - U_{2-;1})$ |
| IV_{FS} | 0         | -1/2      | 0          | 0         | $U_{2+,1}, U_{2-;1}$ |
| V_{FS} | 0         | -1/4      | -1/4       | -1/4      | $U_{3,1}, (U_{2+,1} + U_{2-;1})$ |
| VI_{FS} | 0        | -1/4      | 1/4        | -1/4      | $U_{3,1}, (U_{2+,1} - U_{2-;1})$ |
| VII_{FS} | 0       | -1/2      | 0          | -1/4      | $U_{3,1}, U_{2+,1}, U_{2-;1}$ |
on the SCT,
\[ I_{4V}^{(FS)} = \frac{U_{2s}(\bar{K}_1, \bar{K}_2)}{\kappa} \left[ (\psi^\dagger (K_1) \sigma_1 \psi (K_1))(\psi^\dagger (K_2) \sigma_1 \psi (K_2)) + (\psi^\dagger (K_1) \sigma_2 \psi (K_1))(\psi^\dagger (K_2) \sigma_2 \psi (K_2)) \right]. \]

### 5.2. Symmetry broken states

In this subsection we compute the anomalous scaling dimension of susceptibility along the two SCTs identified above. We also identify the symmetry broken strong coupling fixed points to which the SCTs flow.

Let us consider an insertion of particle-hole pairs carrying a net momentum \( \vec{P} \) on the plane of the loop,
\[ S^{(DW)}_{\mu} (\vec{P}) = \int dK \Phi_\mu (\vec{P}; \bar{K}) \tilde{\psi} (P + K) \gamma_\mu \psi (K) + \text{h.c.} \]

Here the four-dimensional vector \( P \equiv (0, \vec{P}, 0) \). In contrast to the pairing susceptibility, the density wave susceptibility obtains quantum correction from the two diagrams in figure 7. At low energy quantum corrections to the susceptibility at any finite \( \vec{P} \) are suppressed, compared to \( \vec{P} = 0 \). This is because of a lack of phase space for both the virtual particle and hole to be near the loop when \( \vec{P} \neq 0 \). Thus we consider the susceptibility for density wave states with \( \vec{P} = 0 \).

The source \( \Phi_\mu (0; \bar{K}) \) scales as
\[ \partial_\tau \Phi_{0i} = \eta \Phi_{0i}, \]
\[ \partial_\tau \Phi_{1i} = \Phi_{1i} \left[ \eta - \frac{1}{\pi} (U_{2+1} + U_{2-1}) \right], \]
\[ \partial_\tau \Phi_{2i} = \Phi_{2i} \left[ \eta - \frac{1}{\pi} (U_{2+1} - U_{2-1}) \right], \]
\[ \partial_\tau \Phi_{3i} = \Phi_{3i} \left[ \eta - \frac{2}{\pi} U_{3i} \right], \]
where \( \eta = 2 - \epsilon \) is the bare scaling dimension of \( \Phi_{0i} \). Thus at the critical point \( I_{4V}^{(FS)} \) and the ensuing SCT, only \( \Phi_{0i} \) is enhanced, while the scaling dimension of \( \Phi_{0,1,2,3} \) remains unchanged. For \( I_{4V}^{(FS)} \) and the associated SCT \( \Phi_{1i} \) and \( \Phi_{2i} \) are equally enhanced. This degeneracy is protected by the FS-U(1) symmetry. Again the flow equations do not distinguish between angular momentum channel, and the leading instability will be determined by which angular momentum channel has the largest bare couplings (and \( J = 0 \) is allowed). There is however a constraint, namely that the overall Hamiltonian must be Hermitian. This then enforces that the order parameter must be real i.e. either the instability will be in the \( J = 0 \) channel, or if the instability is in a channel with non-zero angular momentum then a real superposition of \( \pm J \) states must arise (i.e. \( \sin J \theta \) or \( \cos J \theta \)).

The flow out of \( I_{4V}^{(FS)} \) is associated with the condensation of \( \psi^\dagger \sigma_3 \psi \). If this occurs in a channel with non-zero \( J \), then it leads to a low energy Hamiltonian \( H \sim (|\bar{K}| - \kappa) \sigma_1 + K \sigma_2 + \Delta_3 \sin (J \theta - \theta_3) \sigma_3 \), where \( \Delta_3 \) and \( \theta_3 \) are real parameters. Such an instability opens a gap almost everywhere on the Weyl loop, with nodes surviving at \( \theta = \theta_3 + n \pi / J \) (integer \( n \)) i.e. this is a gap opening instability that simultaneously breaks the \( \theta \)-rotation symmetry. It also breaks several discrete symmetries, in particular the antunitary symmetries \( \mathcal{P}_k \mathcal{P}_k \) (\( \mathcal{P}_k \)) for even (odd) \( J, \mathcal{P}_0 \), and the mirror symmetry \( \mathcal{P}_2 \). However the symmetries \( \mathcal{P}_k \mathcal{P}_k \) (\( \mathcal{P}_k \)) for even (odd) \( J, \mathcal{P}_0 \) are preserved. Meanwhile, if this occurs in a channel with \( J = 0 \) then the gap function is independent of \( \theta \), and the \( \theta \)-rotation symmetry is preserved, while the discrete symmetries identified above are still broken.

Condensation in the \( J = 0 \) channel uniformly gaps out the Weyl loop, with an effective Hamiltonian of the form
\[ H \sim (|\bar{K}| - \kappa) \sigma_1 + K \sigma_2 + \Delta_3 \sigma_3 \] (real \( \Delta_3 \)) and a dispersion \( E \sim \pm \sqrt{(|\bar{K}| - \kappa)^2 + K^2 + \Delta_3^2} \). Since this is a gap opening instability that preserves an antunitary symmetry \( \mathcal{P}_k \), which squares to \( -1 \), one can ask whether the resulting metallic state is topological or trivial. To address this issue, note that the Weyl loop can be obtained by starting with (spinless) graphene in the \( y - z \) plane with it’s two (opposite sense) Dirac points located...
at $\pm \kappa \hat{y}$ and rotating it through 180 degrees about the $\hat{z}$ axis. Gapping out the two Dirac points of (spinless) graphene with a mass term of the same sign on each Dirac point yields a trivial insulator, and rotating a trivial two dimensional insulator through 180 degrees should yield a trivial three dimensional insulator. Nonetheless, we note that on the plane of the Weyl-loop $P_K$ has the interesting property of mapping the region outside the loop to its interior, which is an unusual implementation of an anti-unitary symmetry that does not appear to fit naturally into the existing classifications.

The flow out of critical point $\Gamma_{SS}$ is associated with the condensation of either $\psi_i \sigma_i \psi$ or $\psi \sigma_3 \psi$. If this occurs in the $J = 0$ channel it leads to an effective Hamiltonian of the form $H \sim (|\tilde{K}| - \kappa) \sigma_1 + K_2 \sigma_2 + \Delta_1 \sigma_1 + \Delta_2 \sigma_2$ where $\Delta_{i,2}$ are real parameters. Such a perturbation shifts the radius of the Weyl loop to $\kappa - \Delta_1$, and shifts it into the plane with $K_2 = -\Delta_2$. A non-zero $\Delta_1$ does not break any symmetries and can be absorbed into a redefinition of the Weyl loop radius $\kappa$. A non-zero $\Delta_2$ breaks the mirror symmetry, and also the discrete antunitary symmetries $P_K$ and $P_\zeta$ which preserves $P_\zeta P_K$ and $P_\zeta$ - it simply shifts the Weyl loop out of the $k_z = 0$ plane. More interesting is the situation where the instability develops in a channel with $J = \neq 0$ such that the effective Hamiltonian takes the form $H \sim (|\tilde{K}| - \kappa) \sigma_1 + K_2 \sigma_2 + \Delta_1 \sin(\theta_1 + \theta_2) \sigma_1 + \Delta_2 \cos(\theta_1 + \theta_2) \sigma_2$ where $\theta_{i,2}$ are constants and $\Delta_{i,2}$ are real. Non-zero $\Delta_1$ will lead to a $\theta$-dependent distortion of the nodal ring in the $K$-plane, whereas non-zero $\Delta_2$ will lead to a $\theta$ dependent distortion perpendicular to the $x$-$y$ plane. These order parameters break the $\theta$-rotation symmetry, and correspond to Pomeranchuk instabilities. The competition between $\Delta_1$ and $\Delta_2$ (in particular whether both $\Delta_1$ and $\Delta_2$ are non-zero, or only one is) will be determined by a Landau Ginzburg calculation similar to those that have already been performed. Note that all of these are gapless phases which continue to have a loop of Dirac nodes.

6. Conclusion

In this work we analyzed the finite coupling instabilities of a rotationally symmetric Weyl-loop semi-metal in three space dimensions. The presence of the loop imposes strong kinematic constraints on short-range interactions, similar to those present in a Fermi liquid. The rotational symmetry of the Weyl loop further endows the problem with enough structure that the functional RG analysis necessary for an extended Fermi surface can be carried out analytically. While the semi-metallic state is stable against weak short-range interactions, symmetry breaking instabilities are present at finite coupling. We deform the dispersion of the system to allow us to access these finite coupling instabilities within the regime of applicability of a weak coupling RG, through an $\epsilon$ expansion type procedure. We find that the only possible instabilities are in the the BCS and the forward scattering channels, which decouple. In the BCS channel the leading instability is to a fully gapped odd angular momentum chiral superconductor, which breaks time reversal symmetry. In the forward scattering channel, various possible instabilities can arise, including a Pomeranchuk instability and a gap opening instability to a trivial insulator. This analysis clarifies what instabilities might be obtained in Weyl loop materials. One question we did not address is the potential competition between instabilities in particle-particle and particle-hole channels. The Pomeranchuk instabilities in the particle-hole channel can presumably co-exist with superconductivity, whereas the gap opening instability in the particle hole channel is likely to compete with superconductivity.

In the case of asymmetric Weyl-loop semi-metal the $SO(2)$ rotational symmetry on the plane of the Weyl-loop is broken down to a discrete $C_6$ symmetry. Although, this will result in mixing of various angular momentum channels during the course RG flow, it is possible that the leading instability still occurs in the lowest angular momentum channel.

Detailed analyses in these directions are left to future works.

Note added: While finalizing the paper we became aware of a related work [61] that focused on the Dirac-loop semi-metal using a different regularization scheme than ours. When applied to the Weyl-loop case a subset of our results were obtained

Appendix A. Computation of quantum corrections

Here we outline the steps for computation of the one-loop quantum corrections to the quartic vertices. Since the computation of all the four one-loop vertex corrections follow identical procedure, we provide the details for...
only the BCS (particle–particle ladder) diagram. It is useful to list the contraction of various matrix vertices. Recall that \((\gamma_0, \gamma_0, \gamma_2, \gamma_2) \equiv (\sigma_0, \sigma_2, -\sigma_2, \sigma_0)\), therefore \(\gamma_1 \gamma_2 = i\gamma_0 \gamma_0 \gamma_1 = i\gamma_2\), and \(\gamma_2 \gamma_0 = i\gamma_2\). With these results we obtain the multiplication rules for \(\gamma\)-matrices listed in table 6.

A.1. BCS diagram

Contraction of two vertices in the BCS channel leads to the quantum correction,

\[
\delta S_{\text{int}}^{(\mu, \nu)}|_{\text{BCS}} = -\frac{4}{2\kappa^2} \int \prod_{n=1}^{4} dK_n dK'_n \delta^{(4)}(K_1 - K_2 + K_3 - K_4) \delta^{(4)}(K'_1 - K'_2 + K'_3 - K'_4) \\
\times \gamma_{\mu a}^{n} \gamma_{\nu b}^{n} \gamma_{\mu a}^{n'} \gamma_{\nu b}^{n'} u_{\mu b}(K_n, K_n'; \bar{K}_n, \bar{K}_n') \psi_{\mu b}(K_n) \psi_{\mu b}(K_n') \psi_{\nu b}(K_n) \psi_{\nu b}(K_n'),
\]

(A1)

Here for notational and computational convenience we have used \(u_{\mu b}\) to identify the coupling functions for the \((\bar{\psi}_{\mu}, \psi_{\nu})^2\) vertex. In particular

\[
u_0 = g_1, \quad \nu_1 = -(g_{2+} + g_{2-}), \quad \nu_2 = -(g_{2+} - g_{2-}), \quad \nu_3 = g_3.
\]

(A2)

where we have suppressed the dependence on loop-coordinates on both sides. Utilizing the definition of the propagator in equation (15), and integrating over \(K_2', K_3',\) and \(K_3\) leads to

\[
\delta S_{\text{int}}^{(\mu, \nu)}|_{\text{BCS}} = -\frac{2}{\kappa^2} \int dK_2 dK_3 dK'_3 (2\pi)^4 \delta^{(4)}(K'_1 - K_2 + K'_1 - K_4) \\
\times \gamma_{\mu a}^{n} \gamma_{\nu b}^{n} \gamma_{\mu a}^{n} \gamma_{\nu b}^{n} \psi_{\nu b}(K_1) \psi_{\nu b}(K_2) \psi_{\nu b}(K_3) \psi_{\nu b}(K_4),
\]

(A3)

where

\[
\Upsilon_{\mu b}(K_1, K_2, K_3, K_4) = \int dQ [\gamma_0 G(Q) \gamma_0] \sigma [\gamma_0 G(K_4 + K_2 - Q) \gamma_0] \\
\times u_{\mu b}(Q, \bar{K}_1, K_2 + K_4 - Q, \bar{K}_2) u_{\nu b}(K_1, K_2 + K_4 - Q, \bar{K}_3, \bar{Q}),
\]

(A4)

with \(A \circ B \equiv A_{a,b} B_{a,b}\), and \((K_2 + K_4 - Q)\) being the unit vector along \((\bar{K}_2 + \bar{K}_4 - \bar{Q})\). Here the internal momentum \(Q\) is restricted to lie within the shell being eliminated (cf figure 2).

The BCS channel is defined by \(\langle \bar{K}_1, \bar{K}_2 \rangle = (-\bar{K}_1, -\bar{K}_2)\). Because we are interested in the IR, we set the external frequency to 0, and external momenta to lie on the loop. Combined with the angular constraint, this implies \(\bar{K}_2 + \bar{K}_4 = 0 = \bar{K}_1 + \bar{K}_3\). Therefore,

\[
\Upsilon_{\mu b}(\bar{K}_1, \bar{K}_2, -\bar{K}_1, -\bar{K}_2) = \int dQ [\gamma_0 G(Q) \gamma_0] \sigma [\gamma_0 G(-Q) \gamma_0] \\
\times u_{\mu b}(\bar{Q}, -\bar{K}_2, -\bar{Q}, \bar{K}_2) u_{\nu b}(\bar{K}_1, -\bar{Q}, -\bar{K}_1, Q),
\]

(A5)

Table 6. Multiplication rules for the \(\gamma\)-matrices.

| \(\gamma\) \(\gamma'\) | \(\gamma_0\) | \(\gamma_0\) | \(\gamma_1\) | \(\gamma_2\) |
|-----------------|---------|---------|---------|---------|
| \(\gamma_0\)    | \(\gamma_0\) | \(\gamma_1\) | \(\gamma_2\) | \(\gamma_2\) |
| \(\gamma_0\)    | \(\gamma_0\) | \(\gamma_1\) | \(\gamma_2\) | \(\gamma_2\) |
| \(\gamma_1\)    | \(-i\gamma_0\) | \(\gamma_0\) | \(\gamma_2\) | \(\gamma_2\) |
| \(\gamma_2\)    | \(-i\gamma_0\) | \(\gamma_0\) | \(\gamma_2\) | \(\gamma_2\) |

\(\gamma_0\), \(\gamma_1\), and \(\gamma_2\) represent the \(\gamma\)-matrices.
Let us define
\[ \Lambda^{-e} V'_\mu(\theta_1 - \theta_2) = u_\mu(\tilde{K}_0, \tilde{K}_1, -\tilde{K}_0, -\tilde{K}_1), \]  
where \( \theta_i \) is the angle the loop momentum \( \kappa \tilde{K}_i \) makes with respect to the x-axis. Thus, we obtain an equivalent expression to equation (A5) in terms of the angles,
\[ T_{\mu}(\theta_1, \theta_2, \theta_1 + \pi, \theta_2 + \pi) = \kappa \Lambda^{-e} \int_{-\pi}^{\pi} \frac{d\theta d\varphi}{(2\pi)^2} \int_{-\infty}^{\infty} \frac{dq}{2\pi} \int_{1-d\varphi}^{A} \frac{dq}{2\pi} V'_\mu(\theta - \theta_2 + \pi) V'_\mu(\theta - \theta - \pi) \times [\gamma_0 G(q_o, q, \varphi) \gamma_0] \times [\gamma_0 G(-q_o, q, -\varphi) \gamma_0]. \]  

(\text{A6})

Therefore, equation \( (A7) \) evaluates to,
\[ T_{\mu}(\theta_1, \theta_2, \theta_1 + \pi, \theta_2 + \pi) = -d\varphi \frac{\kappa \Lambda^{-e}}{16\pi} \sum_{L} e^{-i(\theta_1 - \theta_2)L} \bar{V}_{\mu L} V_{\mu L}. \]  

(\text{A10})

This leads to quantum corrections to the BCS channel,
\[ \delta S^\mu_{\text{int}}[V]_{\text{BCS}} = -\frac{\Lambda^{-e} d\varphi}{4\pi\kappa} \sum_{j} \int_{1}^{4} d\kappa_{n} (2\pi)^4 \delta^{(4)}(k_{1} - k_{2} + k_{3} - k_{4}) \delta(k_{1} + k_{3}) \delta(k_{2} + k_{4}) \times e^{-i(\theta_1 - \theta_2)L} \bar{V}_{\mu L} [\{ \bar{\psi}(K_{1}) \gamma_{0} \gamma_{1} \gamma_{2} \gamma_{3} \psi(K_{2}) \} \{ \bar{\psi}(K_{3}) \gamma_{0} \gamma_{2} \gamma_{3} \gamma_{4} \psi(K_{4}) \}] \]  
\[ - \{ \bar{\psi}(K_{1}) \gamma_{0} \gamma_{3} \gamma_{4} \gamma_{5} \psi(K_{2}) \} \{ \bar{\psi}(K_{3}) \gamma_{0} \gamma_{1} \gamma_{2} \gamma_{4} \psi(K_{4}) \}] \]  
\[ - 2 \{ \bar{\psi}(K_{1}) \gamma_{0} \gamma_{1} \gamma_{2} \gamma_{3} \psi(K_{2}) \} \{ \bar{\psi}(K_{3}) \gamma_{0} \gamma_{3} \gamma_{4} \gamma_{5} \psi(K_{4}) \} \]  

(\text{A12})

The net quantum correction is obtained by summing over \( \mu \) and \( \nu \),
\[ \delta S^\mu_{\text{int}}[V]_{\text{BCS}} = \sum_{\mu, \nu = 0}^{3} \frac{\delta S^\mu_{\text{int}}}{d\varphi} \times [\{ (\tilde{V}_{\mu L})^2 + (\tilde{V}_{\nu L})^2 + (\tilde{V}_{\mu L} \tilde{V}_{\nu L})^2 + (\tilde{V}_{\mu L})^2 + (\tilde{V}_{\nu L})^2 + (\tilde{V}_{\mu L} \tilde{V}_{\nu L})^2 \} (\bar{\psi}_{\gamma_{1}} \psi_{\gamma_{2}})^2]  
\[ + \frac{1}{2} \{ (\tilde{V}_{\mu L})^2 + (\tilde{V}_{\nu L})^2 + (\tilde{V}_{\mu L} \tilde{V}_{\nu L})^2 \} (\bar{\psi}_{\gamma_{1}} \psi_{\gamma_{2}})^2 \]  
\[ + \frac{1}{2} \{ (\tilde{V}_{\mu L})^2 + (\tilde{V}_{\nu L})^2 + (\tilde{V}_{\mu L} \tilde{V}_{\nu L})^2 \} (\bar{\psi}_{\gamma_{1}} \psi_{\gamma_{2}})^2 \]  

(\text{A13})

where the dependence of \( \psi \) on \( \kappa_{n} \) is made implicit for notational convenience.
A.2. Non-BCS diagrams

The forward scattering channels are renormalized by figures 4(b), (c), and (d). In order to compute their contributions it is convenient to distinguish between the FS and ES channels at an intermediate step, and unify them at the end through the relationship

\[
\begin{pmatrix}
U_0^{(ES)} \\
U_1^{(ES)} \\
U_2^{(ES)} \\
U_3^{(ES)}
\end{pmatrix} = \frac{1}{2} \begin{pmatrix}
-1 & -1 & 1 & 1 \\
-1 & 1 & -1 & 1 \\
-1 & 1 & 1 & -1 \\
-1 & -1 & -1 & -1
\end{pmatrix}
\begin{pmatrix}
U_0^{(FS)} \\
U_1^{(FS)} \\
U_2^{(FS)} \\
U_3^{(FS)}
\end{pmatrix},
\]

(A14)

where the primed and their unprimed counterparts defined in the main section are related in the same way as equations (A2) and (A6). The relationship between the ES and FS representation of the coupling functions in the forward scattering channel is defined on the loop through the equivalence of \( L^{(FS)}_{\text{int}} \equiv \sum_{\mu} U_{\mu}^{(FS)} \)

\[
(\psi, \gamma_{\mu}, \psi')^{(FS)} = \sum_{\mu} U_{\mu}^{(FS)} (\psi, \gamma_{\mu}, \psi')^{(FS)} = L^{(FS)}_{\text{int}},
\]

where the subscript in the \( \psi' \) term denotes the arrangement of the fermion momenta in accordance with the definition of the FS and ES channels.

At leading order in \( \Lambda/\kappa \) the external legs of the ZS′ diagram are arranged as in the ES channel, while those of the ZS and P diagrams are arranged as in the FS channel. Repeating the computation presented above for the BCS diagram to the present set of diagrams leads to the quantum corrections

\[
\delta S^{(ZS')}_{\text{int}} = \frac{-\Lambda^* d^*}{4\pi \kappa} \sum_{f} \int \prod_{n=1}^{4} dK_n (2\pi)^d \delta^{(4)}(K_1 - K_2 + K_3 - K_4) \delta(K_1 - K_2) \delta(K_3 - K_4) e^{-i\theta_1 - \theta_2}\]

\[
\times \left[ 2(\psi) \bar{\psi} - (\bar{U}_{1,1}^{(FS)})(\psi) \bar{\psi} - (\bar{U}_{2,1}^{(FS)})(\psi) \bar{\psi} \right],
\]

(A15)

\[
\delta S^{(ZS)}_{\text{int}} = -\frac{-\Lambda^* d^*}{2\pi \kappa} \sum_{f} \int \prod_{n=1}^{4} dK_n (2\pi)^d \delta^{(4)}(K_1 - K_2 + K_3 - K_4) \delta(K_1 - K_2) \delta(K_3 - K_4) e^{-i\theta_1 - \theta_2}\]

\[
\times \left[ 2(\bar{U}_{1,1}^{(FS)})(\psi) \bar{\psi} - (\bar{U}_{2,1}^{(FS)})(\psi) \bar{\psi} \right],
\]

(A16)

\[
\delta S^{(P)}_{\text{int}} = \frac{-\Lambda^* d^*}{2\pi \kappa} \sum_{f} \int \prod_{n=1}^{4} dK_n (2\pi)^d \delta^{(4)}(K_1 - K_2 + K_3 - K_4) \delta(K_1 - K_2) \delta(K_3 - K_4) e^{-i\theta_1 - \theta_2}\]

\[
\times \left[ 2(\psi) \bar{\psi} - (\bar{U}_{1,1}^{(FS)})(\psi) \bar{\psi} \right],
\]

(A17)

Applying the transformation in equation (A14) leads to the net quantum correction to the forward scattering vertices in the FS representation (we drop explicit reference to FS),

\[
\delta S^{(FS)}_{\text{int}} = -\frac{-2\Lambda^* d^*}{\pi \kappa} \sum_{f} \int \prod_{n=1}^{4} dK_n (2\pi)^d \delta^{(4)}(K_1 - K_2 + K_3 - K_4) \delta(K_1 - K_2) \delta(K_3 - K_4) e^{-i\theta_1 - \theta_2}\]

\[
\times \left[ 2(\bar{U}_{1,1}^{(FS)})(\psi) \bar{\psi} - (\bar{U}_{2,1}^{(FS)})(\psi) \bar{\psi} \right],
\]

(A18)

Appendix B. Susceptibilities

In this section we outline the computation of the anomalous dimension of the susceptibilities of both pairing and density-wave channels.
B.1. Pairing susceptibility

Let the quadratic-insertion be

\[ S_{2,\mu}^{(BGS)} = \int_\Lambda dK \Delta^a_{\mu}(\hat{K}) \psi^\dagger(-K) \gamma_\mu \psi(K) + \text{h.c.} \]  

(B1)

The label \( \Lambda \) reminds us of the cutoff for the effective action. The quantum corrections to equation (B1) are generated by contracting it with the quartic vertices in the action, which result in processes represented by figure 6,

\[ \delta S_{2,\mu}^{(BGS)} = -\sum_\nu \int_{(1-\delta\varepsilon)\Lambda} dK \psi^\dagger(-K) \gamma_\nu \Gamma_{\mu\nu}^{BCS}(\hat{K}) \gamma_\mu \psi(K) + \text{h.c.}, \]

(B2)

where

\[ \Gamma_{\mu\nu}^{BCS}(\hat{K}) = \frac{\Lambda^2}{\kappa} \int_\nu dQ \psi^\dagger(\hat{Q}, \hat{K}) \Delta^a_{\mu}(\hat{Q}) \gamma_\nu G(-Q) G(Q). \]

(B3)

Here the primed integration sign implies that the integral is restricted within the high-energy region which corresponds to \( k \in [(1 - \delta\varepsilon)\Lambda, \Lambda] \). After introducing the angular momentum harmonics, the mode elimination leads to

\[ \Gamma_{\mu\nu}^{BCS}(\theta_\mu) = d\varepsilon \left[ \frac{8\pi}{\delta_0(\{ V_{\nu}\}) = 0}, \right. \]

\[ \left. 8\pi \delta_1(\{ V_{\nu}\}) = -(V_{\nu} - V_{\nu}^{+}) + 2V_{\nu}^{+} = 2f_{\nu}, \right. \]

\[ 8\pi \delta_2(\{ V_{\nu}\}) = -(V_{\nu} - V_{\nu}^{-}) - 2V_{\nu}^{+} = -2f_{\nu}, \]

\[ 8\pi \delta_3(\{ V_{\nu}\}) = -(V_{\nu} + V_{\nu}^{+}) - 4V_{\nu}^{+} = -4f_{\nu}. \]

(B4)

Adding the quantum correction to \( S_{2,\mu}^{(BGS)} \) and rescaling all dimensionful quantities to restore the cutoff to \( \Lambda \) gives the beta function of \( \Delta_{\mu\nu} \)

\[ \partial_{\varepsilon} \Delta_{\mu
u} = \Delta_{\mu\nu}[\varepsilon + \delta_\mu(\{ V_{\nu}\})]. \]

(B7)

B.2. Density wave susceptibility

Figures 7(a) and (b) leads to the quantum corrections,

\[ \delta S_{2,\mu}^{(DW)}(\vec{P})|_a = -2 \sum_\nu \int_{(1-\delta\varepsilon)\Lambda} dK \psi^\dagger(P + K) \gamma_\nu \Gamma_{\mu\nu}^{(DW)a}(\vec{P}, \vec{K}) \gamma_\mu \psi(K) + \text{h.c.}, \]

\[ \delta S_{2,\mu}^{(DW)}(\vec{P})|_b = 2 \sum_\nu \int_{(1-\delta\varepsilon)\Lambda} dK \Gamma_{\mu\nu}^{(DW)b}(\vec{P}, \vec{K}) \psi^\dagger(P + K) \gamma_\nu \psi(K) + \text{h.c.}, \]

(B8)

respectively, where \( (u_\nu) \) are defined in equation (A2)

\[ \Gamma_{\mu\nu}^{(DW)a}(\vec{P}, \vec{K}) = \frac{1}{\kappa} \int dQ \Phi_\mu(\vec{P}) u_\nu(\vec{Q}, \vec{R}, (\vec{K} + \vec{P}), (Q + P)) G(Q + P) \gamma_\nu G(Q), \]

\[ \Gamma_{\mu\nu}^{(DW)b}(\vec{P}, \vec{K}) = \frac{1}{\kappa} \int dQ \Phi_\mu(\vec{P}) u_\nu(\vec{Q}, (Q + P), (\vec{K} + \vec{P}), \vec{K}) \text{tr} \{ \gamma_\nu G(Q + P) \gamma_\nu G(Q) \}. \]

(B9)

The difference in overall sign between the two quantum corrections in equation (B8) arises from the fermion-loop in figure 7(b). We set \( \vec{P} = 0 \), and apply the steps in appendices A2 and B1 to obtain the beta functions for \( \Phi_{\mu\nu} \) quoted in the main section.
