Abstract

Two results are presented for reduced Yang-Mills integrals with different symmetry groups and dimensions: the first is a compact integral representation in terms of the relevant variables of the integral, the second is a method to analytically evaluate the integrals in cases of low order. This is exhibited by evaluating a Yang-Mills integral over real symmetric matrices of order 3.

1 Introduction

In recent years the complete reduction of the $D$-dimensional $SU(N)$ Yang-Mills theory was studied by many authors. The reduced supersymmetric partition function is an ordinary multiple integral of the form

\begin{equation}
Z = \int \prod_{\mu=1}^{D} dX_\mu \, d\Psi \, e^{-S(X,\Psi)}
\end{equation}

where the Euclidean action is

\begin{equation}
S(X,\Psi) = -\text{Tr} [X_\mu, X_\nu] [X_\mu, X_\nu] - \text{Tr} \, \Psi \, \Gamma^\mu [X_\mu, \Psi]
\end{equation}

and the matrix-valued gauge potentials $X_\mu$ and their fermionic superpartners $\Psi$ have values in the $SU(N)$ Lie algebra

\begin{align*}
X_\mu &= X_\mu^a T^a, & \Psi &= \Psi^a T^a \\
[T^a, T^b] &= i f^{abc} T^c, & \text{Tr} T^a T^b &= \delta_{ab}
\end{align*}

There are several motivations to investigate these integrals both in the maximally supersymmetric models, as well as in cases with less supersymmetry\textsuperscript{[1] [2] [3] [4]}. We
refer to some recent papers \[5\] \[6\] for introduction to the subject, review of recent results and further references. The interest in understanding these integrals is such that the study of simpler models without fermionic partners and for a variety of groups has been considered very useful, also by means of extensive numerical investigations \[7\] \[8\] \[9\] \[10\] \[11\]. Unfortunately, a general rigorous method for computing eq. (1.1) is still unknown. The development of techniques to understand these integrals for various values of \(N\) and \(D\) is very desirable, as well as techniques which allow the analytic evaluation of the integrals in cases of small order of the matrices.

In this letter we concentrate on the simpler, pure bosonic integrals of the form

\[
Z = \int \prod_{\mu=1}^{D} dX_\mu \ e^{\text{Tr} [X_\mu, X_\nu] [X_\mu, X_\nu]} \quad (1.4)
\]

The existence conditions and the convergence properties of (1.1) and (1.4) (and of the corresponding correlation functions) have been analytically established in the most general case and for any compact semi-simple gauge group recently in \[6\]. As it is well known, these models, besides the global unitary invariance for similarity transformation of the matrices, have a rotational \(SO(D)\) vector invariance. The latter is the crucial ingredient for our two results: the first is a compact representation of eq. (1.4) in terms of its natural variables. It holds for generic values of \(D\) and any group. The second result is a technique to analytically evaluate the integrals in the case of small-order matrices. We exploit it in the evaluation of a 5D integral corresponding to the Y-M integral over 3 x 3 real symmetric matrices. It seems likely that both results should be helpful also for the supersymmetric integrals.

It is useful to parametrize the random matrices with their independent entries. For instance we shall consider the ensemble of real traceless symmetric matrices of order 3:

\[
X^\mu = \begin{pmatrix} a^\mu & u^\mu & v^\mu \\ u^\mu & -a^\mu - b^\mu & z^\mu \\ v^\mu & z^\mu & b^\mu \end{pmatrix} \quad ; \quad \mu = 1 \ldots D \quad (1.5)
\]

The action \(S(X)\) is easily evaluated as a polynomial in the scalar products of the five independent \(D\)-dimensional vectors. The ensemble has the unitary invariance \(SO(3)\) and we evaluate, for \(D > 6\)

\[
Z_{SO(3)} = \int d^D a \ d^D b \ d^D u \ d^D v \ d^D z \ e^{-S(X_\mu)} = \\
= \frac{\pi^{\frac{D}{2}+1} \ 3^{1-D} \ 2^{6-D} \ \Gamma \left( \frac{D}{2} \right) \ \Gamma \left( \frac{D}{2} - \frac{1}{2} \right) \ \Gamma \left( \frac{D}{2} - \frac{1}{2} \right)}{(D-4)(D-6) \ \Gamma \left( \frac{D}{2} - \frac{1}{2} \right) \ \Gamma \left( \frac{D}{2} - \frac{1}{2} \right)} \quad (1.6)
\]

This should not be confused with the ensemble of real anti-symmetric matrices, also having the same \(SO(3)\) unitary invariance. The latter ensemble is parametrized by three \(D\)-dimensional vectors and corresponds to the only known integral which was exactly evaluated in every dimension both in the bosonic and supersymmetric case \[2\] \[3\] \[12\]. Further evaluations were given for supersymmetric integrals in fixed dimension by the deformation technique \[13\], reproducing the conjecture of \[14\] and afterwards numerically confirmed for small gauge groups in \[7\].
2 A compact natural representation

Let us consider an ensemble of matrices \( X_\mu, \mu = 1, \ldots, D \), parametrized by a number \( n \) of \( D \)-dimensional real vectors. For instance, in the familiar ensemble of Hermitian traceless matrices of order \( N \), invariant under the global \( SU(N) \) group, there are \( n = N^2 - 1 \) real vectors. The action \( S = -\text{Tr}[X_\mu X_\nu] \) is a homogeneous polynomial in the components of the vectors, and it only depends on the \( n(n+1)/2 \) scalar products of the \( n \) vectors, as it follows from the vector \( SO(D) \) invariance of the model. The bosonic partition function is a multiple integral over \( nD \) variables, with an integrand which is a function of \( n(n+1)/2 \) variables. If \( n \leq D \) the vectors are generically linearly independent and it seems desirable to express the partition function as an integral over the natural variables, that is the scalar products. This is expressed by the equation

\[
Z = \int \prod_{j=1}^{n} d\vec{v}_j F(B) = \int \prod_{i \leq j}^{R} db_{ij} F(B) I_{n,D}(B) ,
\]

where \( \Omega \) stands for the usual Boltzmann weight (possibly multiplied by a Pfaffian or a determinant resulting from the integration over the fermionic fields), the region of integration \( R \) is described later in this section and \( I_{n,D}(B) \) is the joint probability density for \( n \) vectors \( \vec{v}_i \), with given scalar products \( b_{ij} = \vec{v}_i \cdot \vec{v}_j \) in the \( D \)-dimensional Euclidean space.

**Proposition 1:**

\[
I_{n,D}(B) \equiv \int \prod_{i=1}^{n} d\vec{v}_i \prod_{1 \leq j < k \leq n} \delta (b_{jk} - \vec{v}_j \cdot \vec{v}_k) =
\]

\[
= \left[ \text{det}_n(B) \right]^{(D-n)/2} \frac{\prod_{j=1}^{n} \Omega_{D-j}}{2} ,
\]

where \( \Omega_{D-1} = 2^{D/2} \Gamma(D/2) \), \( \text{det}_n(B) = (l_1 l_2 \ldots l_n)^2 \text{det}_n(Z) \) (2.2)

**Proposition 1** may be proved from \(^1\)

**Proposition 2:** for a given set of \( n-1 \) linearly independent vectors \( \vec{v}_k, k=1, \ldots, n-1 \), in a real \( D \)-dimensional space, \( n \leq D \),

\[
i_n = \int d\vec{v}_n \delta \left( 1 - \frac{\vec{v}_n^2}{l_n^2} \right) \delta \left( z_{1n} - \frac{\vec{v}_1 \cdot \vec{v}_n}{l_1 l_n} \right) \ldots \delta \left( z_{n-1,n} - \frac{\vec{v}_{n-1} \cdot \vec{v}_n}{l_{n-1} l_n} \right) =
\]

\[
= \frac{\Omega_{D-n} l_D}{2} \frac{\text{det}_n(Z)^{(D-n-1)/2}}{\text{det}_{n-1}(Z)^{(D-n)/2}} = \frac{\Omega_{D-n}}{2} l_{n+1} \prod_{j=1}^{n+1} \left( \frac{\text{det}_n(B)^{(D-n-1)/2}}{\text{det}_{n-1}(B)^{(D-n)/2}} \right)
\] (2.3)

\(^1\)A different proof of eq. (2.2) may also be given by writing the integral representation for the delta functions and evaluating the integral of a random real symmetric matrix in external field.
where \( \det_{n-1}(B) \) is the leading principal minor obtained by deleting the last row and last column of \( B \).

We outline here a proof for Proposition 2. The vector \( \vec{v}_n \) may be decomposed on the basis of the \( n-1 \) external vectors and a \( D-(n-1) \)-dimensional vector \( \vec{v}_{n\perp} \) in the orthogonal subspace:

\[
\vec{v}_n = \omega_1 \vec{v}_1 + \ldots + \omega_{n-1} \vec{v}_{n-1} + \vec{v}_{n\perp},
\]

\[
\int d\vec{v}_n = \sqrt{\det_{n-1}(B)} \int d^{D-n+1} \vec{v}_{n\perp} \left( \prod_{j=1}^{n-1} \int_{-\infty}^{\infty} d\omega_j \right) \tag{2.4}
\]

The vector \( \vec{v}_{n\perp} \) only occurs in the first delta function \( \delta(1 - \vec{v}_{n\perp}^2/l_n^2) \), and its integral is trivial:

\[
\int d^{D-n+1} \vec{v}_{n\perp} \delta \left( 1 - \frac{\vec{v}_{n\perp}^2 + (\sum \omega_j \vec{v}_j)^2}{l_n^2} \right) = \Omega_{D-n} \int_0^\infty d\rho \rho^{D-n} \delta \left( 1 - \frac{\rho^2 + (\sum \omega_j \vec{v}_j)^2}{l_n^2} \right) = \frac{\Omega_{D-n} l_n^2}{2} \left[ l_n^2 - \left( \sum \omega_j \vec{v}_j \right)^2 \right]^{(D-n-1)/2} = \left( \sum \omega_j \vec{v}_j \right)^2 = \sum_{j,k=1}^{n-1} \omega_j \omega_k b_{jk} \tag{2.5}
\]

The remaining \( n-1 \) delta functions fix the \( \omega_j \) as the solution of the system \( \sum_{j=1}^{n-1} b_{ij} \omega_j = l_i l_n z_{in} = b_{in}, i = 1, \ldots, n-1 \), that is \( \bar{\omega}_j = \sum_{s=1}^n [B^{-1}]_{js} b_{sn} \).

\[
\overline{l_n^2} = \left( \sum \omega_j \vec{v}_j \right)^2 = b_{nn} - \sum_{j,k=1}^{n-1} \bar{\omega}_j \bar{\omega}_k b_{jk} = b_{nn} - \sum_{j=1}^{n-1} \bar{\omega}_j b_{jn} = b_{nn} - \sum_{j,s=1}^{n-1} b_{ns} [B^{-1}]_{sj} b_{jn} = \frac{\det_n(B)}{\det_{n-1}(B)} \tag{2.6}
\]

Finally Proposition 2 is proved after using

\[
\int_0^\infty \prod_{j=1}^{n-1} d\omega_j \prod_{k=1}^{n-1} \delta \left( z_{kn} - \sum_{r=1}^{n-1} \omega_r l_r z_{kr} \right) = \frac{\prod_{j=1}^{n-1} l_j l_{n-1}}{l_1 l_2 \ldots l_{n-1} \det_{n-1}(Z)} \tag{2.7}
\]

Proposition 1 follows now from Proposition 2 since the joint density \( I_{n,D}(B) \), from its definition, may be written as the product of the integrals \( i_k \).

The cosines \( z_{ij} \) are bound by \(-1 \leq z_{ij} \leq 1\) but the derivation of eq. (2.2) implies the stricter bound that \( \det_k(Z) > 0 \) for each \( k, k = 1, \ldots, n \), which is necessary and sufficient condition for the real symmetric matrix \( Z \) to have all the eigenvalues positive.

Eqs. (2.3), (2.4) provide a very simple reduction of the partition function to the smaller number of relevant variables which has general validity for different matrix ensembles and dimensions. It may be useful for numerical integration and possibly for more general purposes when averaging over random vectors. The partition function expressed

\[2\] See for instance chapter 21 of ref. [13], where one studies averages over random orthogonal vectors. Our eq. (2.2) for \( n = 2, z_{12} = 0 \), reproduces the result eq. (21.1.11) of [13].
as multiple integral over the scalar products is closely related to the Ingham-Siegel integral \[14\]. In fact the well known Yang-Mills integral for the $SU(2)$ invariant ensemble is a trivial case. After parametrization of the hermitian traceless matrices of order 2 with 3 real entries, one obtains

$$Z_{SU(2)} = \int \prod_{j=1}^{3} d\vec{v}_j \ e^{-S_{SU(2)}} =$$

$$= \frac{\pi^{3(D-1)/2}}{\Gamma \left( \frac{D}{2} \right) \Gamma \left( \frac{D-1}{2} \right) \Gamma \left( \frac{D+1}{2} \right) } \int_{B>0} dB \ e^{-S_{SU(2)}} \ [\det(B)]^{(D-4)/2} ,$$

where

$$S_{SU(2)} = 16 \left( b_{11}b_{22} + b_{11}b_{33} + b_{22}b_{33} - b_{12}^2 - b_{13}^2 - b_{23}^2 \right) = 16 \det(B) \ tr \left( B^{-1} \right) .$$

We change integration matrix variables $C_{ij} = (\det B)[B^{-1}]_{ij}$, $dB = (\det C)^{-1} dC$, $\det B = (\det C)^{1/2}$

$$\int_{B>0} dB \ e^{-S_{SU(2)}} \ [\det(B)]^{(D-4)/2} = 2^{-3D} \int_{C>0} dC \ (\det C)^{(D-8)/4} e^{-\tr C} =$$

$$= \frac{\pi^{3/2}}{2^{3D}} \Gamma \left( \frac{D}{4} \right) \Gamma \left( \frac{D-1}{4} \right) \Gamma \left( \frac{D+1}{4} \right)$$

\[2.8\]

Since for the $SU(2)$ case in $D = 10$ the Pfaffian arising from the fermion integration is proportional to $(\det B)^4$, also the supersymmetric $SU(2)$ integral is easily obtained, reproducing the result of \[3\] \[2\].

3 Reduction by iterated projections

A useful technique which avoids the inconvenience of the Jacobian and positivity requirements is the Reduction by iterated projections. The price is a more complicated expression of the action. To put it on general ground, let us consider the integral in $n$ real vector variables of a function which only depends on the scalar products in $D$ dimensions

$$I = \int d^D x_1 d^D x_2 \ldots d^D x_n F \left( (x_i|x_j)_D; i \leq j \right)$$

\[3.1\]

Proposition 3

Case $D \geq n$:

$$I = \Omega_{D-1} \ldots \Omega_{D-n} \int_0^\infty dx_1 x_1^{D-1} \ldots \int_0^\infty dx_n x_n^{D-n} \int_{-\infty}^{\infty} \prod_{i<j} dx_{ij} F(...) \ldots$$

\[3.2\]

$$(x_i|x_j)_D = x_1 x_{ij} + \ldots + x_{i-1} x_{i-1,j} + x_i x_{ij}, \quad i \leq j$$

\[3.3\]
Case $D < n$:

$$I = \Omega_{D-1} \ldots \Omega_0 \int_0^\infty dx_1 x_1^{D-1} \ldots \int_0^\infty dx_D \int_{-\infty}^\infty \prod_{i<j} dx_{ij} F(...)$$

(3.4)

$$(x_i | x_j)_D = x_{i1} x_{j1} + \ldots + x_{iD} x_{jD}, \quad D < i \leq j;$$

$$(x_i | x_j)_D = x_{i1} x_{j1} + \ldots + x_{iD} x_{j1}, \quad i < j, i \leq D$$

(3.5)

Proof: The rotational invariance in the space $R^D$ of all vectors allows us to choose the vector $x_1$ as the polar direction. Any other vector $x_i$ is then described by its component parallel to $x_1$, denoted as $x_{i1}$ living in $R$, and a vector orthogonal to it, which (with abuse of language) we again denote $x_i$, living in the space $R^{D-1}$. Thus we have the first sweep

$$I = \Omega_{D-1} \int_0^\infty dx_1 x_1^{D-1} \int_{-\infty}^\infty dx_{12} \ldots dx_{1n} \int dx_2^{D-1} \ldots dx_n^{D-1} F(...)$$

(3.6)

where the scalar products in $F$ are easily evaluated:

$$(x_1 | x_1)_D = x_1^2, \quad (x_1 | x_i)_D = x_{i1}, \quad (x_i | x_j)_D = x_{i1} x_{j1} + (x_i | x_j)_{D-1}, \quad 1 < i \leq j$$

Next we choose the vector $x_2$ as the polar direction in $R^{D-1}$ and introduce accordingly new real variables $x_{2i}$ and vectors $x_i$ in $R^{D-2}$, $i = 3, \ldots, n$. The integral is now:

$$I = \Omega_{D-1} \Omega_{D-2} \int_0^\infty dx_1 x_1^{D-1} \int_0^\infty dx_2 x_2^{D-2} \int_{-\infty}^\infty dx_{12} \ldots dx_{1n} dx_{23} \ldots dx_{2n}$$

$$\int dx^{D-2} x_3 \ldots dx^{D-2} x_n F(...)$$

(3.7)

The scalar products in $R^{D-1}$ that still appear in $F$ are evaluated:

$$(x_2 | x_2)_{D-1} = x_2^2, \quad (x_2 | x_i)_{D-1} = x_{i2}, \quad (x_i | x_j)_{D-1} = x_{i2} x_{j2} + (x_i | x_j)_{D-2}, \quad 2 < i \leq j$$

The process is iterated and we have two situations: $D \geq n$, $D < n$. In the first case we can iterate the process $n$ times, to obtain an integral in $n$ positive variables $x_1 \ldots x_n$ and $\frac{1}{2} n(n-1)$ real variables $x_{ij}$, $i < j$. When $D < n$ the process can be iterated only $D$ times; we obtain $D$ positive variables $x_1 \ldots x_D$, and $\frac{1}{2} D(2n - D - 1)$ real variables $x_{ij}$, $i < j$, $i = 1 \ldots D$.

4 Y-M integral with $3 \times 3$ real symmetric matrices

The $3 \times 3$ traceless real symmetric matrices of the Yang-Mills integral are parametrized as indicated in eq. (3.5). The partition function

$$Z_{SO(3)} = \int d^D a d^D b d^D u d^D v d^D z e^{S_0}$$

(4.1)
contains the following expression for the action, in terms of scalar products like 
\((a|b) = \sum_{\mu} a_{\mu} b^{\mu}\):

\[
S_0 = -4[a^2 u^2 - (a|u)^2] - [a^2 v^2 - (a|v)^2] - [a^2 z^2 - (a|z)^2] - b^2 u^2 - (b|u)^2, \\
-4[b^2 v^2 - (b|v)^2] - [b^2 v^2 - (b|v)^2] - [u^2 z^2 - (u|z)^2] - [v^2 z^2 - (v|z)^2] \\
-4[u^2 v^2 - (u|v)^2] - 4[(a|b) - (u|a)(a|b)] - 4(z^2 (a|b) - (z|a)(z|b)) \\
+2[v^2 (a|b) - (v|a)(v|b)] + 6(a|z)(u|v) - 6(a|v)(u|z) \\
+6(b|u)(v|z) - 6(b|e)(u|z) \\
\]

(4.2)

The huge invariance of the action can be exploited by reducing to a smaller number of effective variables. We have been able to compute \(Z_{SO(3)}\) by using the technique of successive projections, described in the previous Section.

For \(D \geq 5\) the reduction yields a 15-dimensional integral:

\[
Z_{SO(3)} = \Omega_{D-1} \ldots \Omega_{D-5} \int_{-\infty}^{\infty} dv v^{D-1} \int_{-\infty}^{\infty} dz z^{D-2} \int_{-\infty}^{\infty} du u^{D-3} \int_{-\infty}^{\infty} da a^{D-4} \int_{-\infty}^{\infty} db b^{D-5} \\
\int z_{1} dz_{1} du_{1} da_{1} db_{1} dz_{2} du_{2} da_{2} db_{2} dz_{3} du_{3} da_{3} db_{3} e^{S_{1} + S_{2}} e^{S_{3}} e^{S_{4}} \\
\]

(4.3)

where the action in the reduced variables has been decomposed in terms with the following meaning. \(S_1\) includes all terms in the variables \(a, b, u\) and \(v\) that terminated the reduction procedure and can be integrated immediately:

\[
S_1 = -4a^2 v^2 + (z^2 + z_0^2) + 4(u^2 + u_0^2 + u_0^2) \\
-4(b^2 + b_0^2) v^2 + 4(z^2 + z_0^2) + (u^2 + u_0^2 + u_0^2) \\
+8ab_0 v^2 - 2(z^2 + z_0^2 + u^2 + u_0^2 + u_0^2) \\
\]

(4.4)

The integration yields a factor that does not depend on the 6 variables \(a, b, u, v, z\). These variables appear in the action quadratically and linearly. The quadratic terms are collected in \(S_2\) and the linear terms in \(S_3\), in a form suitable for a Gaussian integration:

\[
S_2 = -4X^T MX \quad ; \quad S_3 = 8eX^T Y \\
\]

where \(X = \begin{pmatrix}
    a + 2b \\
    2a + b \\
    a + 2b \\
    2a + b \\
    a + 2b \\
    2a + b \\
\end{pmatrix} \), \(Y = \begin{pmatrix}
    -z_{u_0} \\
    -z_{u_0} \\
    2u_{x_0} - z_{u_0} \\
    -u_{x_0} + 2z_{u_0} \\
    2u_{x_0} \\
    -u_{x_0} \\
\end{pmatrix} \)

\[
M = \begin{pmatrix}
    z^2 & 0 & -z_{u_0} & 0 & 0 & 0 \\
    0 & u^2 + u_0^2 & 0 & -u_z u_{v_0} & 0 & -u u_{v_0} \\
    -z_{u_0} & 0 & v^2 + z^2 & -v^2 & 0 & 0 \\
    0 & -u_z u_{x_0} & -v^2 & v^2 + u^2 + u_0^2 & 0 & -u u_{z_0} \\
    0 & 0 & 0 & 0 & v^2 + z^2 + z_0^2 & -v^2 \\
    0 & -u u_{v_0} & 0 & -u u_{z_0} & -v^2 & v^2 + u_0^2 + u_0^2 \\
\end{pmatrix} \\
\]

7
The remaining part $S_4$ of the action contains terms in the reduced variables originating from the off diagonal matrix elements, namely $v$, $z$, $u_1$, $u_2$ and $u_3$:

$$S_4 = -4z^2(v^2 + u_1^2) - 4u_2^2(v^2 + z_0^2) - 4u_2^2(v^2 + z_0^2) + 8zu_1u_2z_0 \quad (4.6)$$

As we described, the $Z_{SO(3)}$ integral can be done in independent steps. We have a factor coming from the triple integral:

$$I_1 = \int_0^\infty da a^{D-4} \int_0^\infty db b^{D-5} da \int_{-\infty}^\infty db u e^{S_1} =$$

$$= \frac{\sqrt{\pi}}{4} (12)^{-D+3} \frac{\Gamma \left( \frac{D-3}{2} \right) \Gamma \left( \frac{D-4}{2} \right)}{\left[ v^2(u^2 + u_1^2 + u_2^2 + z^2 + z_0^2) + (z^2 + z_0^2)(u^2 + u_1^2 + u_2^2) \right]^{(D-3)/2}} \quad (4.7)$$

At the same time one can do the Gaussian integral

$$I_2 = \int_{-\infty}^\infty da db dz du \, e^{S_2 + S_3} =$$

$$= \frac{1}{12^3} \int d^D \, X \, e^{-X^tX + 4vX^tY} = \frac{\pi^3}{12^3} (\det M)^{-1/2} e^{S_5} \quad (4.8)$$

The computations for inverting the matrix $M$ and evaluating the quadratic form $S_5 = 4v^2Y^tM^{-1}Y$ were done with the aid of Mathematica:

$$S_5 = 4((v^2 + z_0^2)(u^2 + u_1^2) + 4z^2(v^2 + u_1^2) - 8zu_1u_2z_0 - 4 \frac{(uvz)^2}{z^2 + z_0^2} - 4 \frac{(uvz)^2}{u^2 + u_1^2 + u_2^2}, \quad \det M = v^4z^2u^2(z^2 + z_0^2)(u^2 + u_1^2 + u_2^2)$$

In summing the expressions $S_4$ and $S_5$, to obtain the residual action, many terms cancel:

$$S_4 + S_5 = -4z^2u^2 - 4v^2z^2z^2u^2(u^2 + u_1^2 + u_2^2 + z^2 + z_0^2) + \frac{(uvz)^2}{z^2 + z_0^2}(u^2 + u_1^2 + u_2^2) \quad (4.9)$$

We arrive at the following stage of computation of the full integral:

$$Z_{SO(3)} = \frac{1}{4} \pi^{7/2} 12^{-D} \Gamma \left( \frac{D}{2} - 2 \right) \Gamma \left( \frac{D}{2} - \frac{3}{2} \right) \Omega_{D-1} \cdots \Omega_{D-5} I_3 \quad (4.10)$$

where we still have to evaluate

$$I_3 = \int_0^\infty dv \nu^{D-3} \int_0^\infty dz \nu^{D-3} \int_0^\infty du \nu^{D-4} \int_{-\infty}^\infty dz \nu \, du \, du \, e^{S_4 + S_5}$$

$$\left[ (u^2 + u_1^2 + u_2^2)(z^2 + z_0^2) \right]^{-1/2} \quad (4.10)$$

Since the variables $u_1$ and $u_2$ always appear in the combination $u_1^2 + u_2^2 = \rho^2$, we introduce polar variables obtaining a factor $2\pi$ from angle integration. It is also convenient to change from the variable $v$ to the variable $x$:

$$x = \nu \frac{u^2 + \rho^2 + z^2 + z_0^2}{(u^2 + \rho^2)(z^2 + z_0^2)}$$
\[ I_3 = 2\pi \int_0^\infty dx \: x^{D-3} (1 + x^2) \frac{D-3}{2} \int_0^\infty dz \: z^{D-3} \int_0^\infty du \: u^{D-4} e^{-4u^2 z^2 (1 + x^2)} \]
\[ \int_0^\infty \rho \: d\rho \int_{-\infty}^\infty dw (u^2 + \rho^2 + z^2 + z_w^2)^{-\frac{D}{2} + 1} \]

(4.11)

The double integral in \( \rho \) and \( z_w \) is elementary, and poses the restriction \( D > 5 \) for convergence,

\[ \int_{-\infty}^\infty dz_w \int_0^\infty \rho \: d\rho \: (u^2 + \rho^2 + z^2 + z_w^2)^{-\frac{D}{2} + 1} = (z^2 + u^2)^{-\frac{D}{2} + \frac{3}{2}} B \left( \frac{D - 5}{2}, \frac{3}{2} \right) \]

The remaining integrals are easily done with the substitution \( u = (1 + x^2)^{-1/4} \cos \theta \) and \( z = (1 + x^2)^{-1/4} r \sin \theta \). We obtain, with the further restriction \( D > 6 \) for convergence,

\[ I_3 = 2\pi B \left( \frac{D - 5}{2}, \frac{3}{2} \right) \int_0^\infty dx \: x^{D-3} (1 + x^2)^{-\frac{D}{2} + \frac{3}{2}} \int_0^{\pi/2} d\theta \: \cos^{D-4} \theta \sin^{D-3} \theta \]
\[ \int_0^\infty dr r^{D-1} e^{-4r^2 \sin^2 \theta \cos^2 \theta} = 4\pi^{5/2} 2^{-\frac{D}{2}} \frac{\Gamma \left( \frac{D}{2} - 1 \right) \Gamma \left( \frac{D}{2} - 3 \right)}{\Gamma \left( \frac{D}{2} - \frac{1}{2} \right)} \]

(4.12)

The final result, for \( D > 6 \) is:

\[ Z_{SO(3)} = \frac{\pi \frac{\Gamma \left( \frac{D}{2} + 1 \right) \Gamma \left( \frac{D}{2} - 1 \right) \Gamma \left( \frac{D}{2} - 3 \right)}{(D - 4)(D - 6) \Gamma \left( \frac{D}{2} - \frac{1}{2} \right) \Gamma \left( \frac{D}{2} - \frac{3}{2} \right)}} \]

(4.13)

In the case \( D = 4 \), one should truncate the reduction by projections, as described in the previous section (since the 5 vectors are not linearly independent). This produces a set of 14 integration variables and an action which, in simple terms, are obtained from eq. (4.3) by suppressing the integral in \( b \) and all terms containing \( b \) in \( S_1 \). We checked that also in this case the integrations lead to a divergent result.

Acknowledgments

One author (G.M.C.) wishes to thank M.Bonini, R.De Pietri, M.P.Manara for useful discussions, another author (G.V.) wishes to thank J.Wheater for stimulating discussions and comments. The work of G.V. is supported by the EU network on “Discrete Random Geometry”, grant HPRN-CT-1999-00161.
