ABSTRACT Let $\mathcal{R} = \mathbb{F}_{p^m}[u]/\langle u^3 \rangle$ be the finite commutative chain ring, where $p$ is a prime, $m$ is a positive integer and $\mathbb{F}_{p^m}$ is the finite field with $p^m$ elements. In this paper, we determine all repeated-root constacyclic codes of arbitrary lengths over $\mathcal{R}$ and their dual codes. We also determine the number of codewords in each repeated-root constacyclic code over $\mathcal{R}$. We also obtain Hamming distances, RT distances, RT weight distributions and ranks (i.e., cardinalities of minimal generating sets) of some repeated-root constacyclic codes over $\mathcal{R}$. Using these results, we also identify some isodual and maximum distance separable (MDS) constacyclic codes over $\mathcal{R}$ with respect to the Hamming and RT metrics.

INDEX TERMS Cyclic codes, local rings, negacyclic codes, optimal codes.

I. INTRODUCTION

Constructing codes that are easy to encode and decode, can detect and correct many errors and have a sufficiently large number of codewords is the primary aim of coding theory. Several metrics (e.g. Hamming metric, Lee metric, RT metric, etc.) have been introduced to study error-detecting and error-correcting properties of a code with respect to various communication channels. Among the prevalent metrics in coding theory, the Hamming metric is the most studied metric and it is suitable for orthogonal modulated channels. The Singleton bound [31] is an upper bound on the size $M$ of an arbitrary block code with respect to the Hamming metric:

$$M \leq q^{n-d+1},$$

where $q$ is the cardinality of the code alphabet, $n$ is the block length and $d$ is the Hamming distance of the code. Linear codes that attain the Singleton bound are called maximum distance separable (MDS) codes with respect to the Hamming metric. Later, motivated by the problem to transmit messages over several parallel communication channels with some channels not available for transmission, a non-Hamming metric, called the Rosenbloom-Tsfasman metric (or RT metric), was introduced by Rosenbloom and Tsfasman [30]; they also derived Singleton bound for the RT metric. Linear codes that attain the Singleton bound for the RT metric are called MDS codes with respect to the RT metric. MDS codes have the highest possible error-detecting and error-correcting capabilities for given code length, code size and alphabet size, hence they are considered optimal codes in that sense. This has encouraged many coding theorists to further study and construct MDS codes with respect to various metrics (see [20], [23], [39]). Recently, Li and Yue [24] determined Hamming distances of all repeated-root cyclic codes of length $5p^s$ over $\mathbb{F}_{p^m}$ and identified all MDS codes within this class of codes, where $p$ is a prime, $s$, $m$ are positive integers and $\mathbb{F}_{p^m}$ is the finite field of order $p^m$. In this paper, we shall also find MDS codes with respect to Hamming and RT metrics within the family of constacyclic codes over $\mathbb{F}_{p^m}[u]/\langle u^3 \rangle$.

Berlekamp [4] first introduced and studied constacyclic codes over finite fields, which have a rich algebraic structure and are generalizations of cyclic and negacyclic codes. For recent works on constacyclic codes over finite fields, please refer to [32], [33], [37]. Calderbank et al. [6], Hammons et al. [21] and Nechaev [28] related binary non-linear codes (e.g. Kerdock and Preparata codes) to linear codes over the finite commutative chain ring $\mathbb{Z}_4$ of integers modulo 4 with the help of a Gray map. Since then, codes over finite commutative chain rings have received a great deal of attention. However, their algebraic structures are known only in a few cases. Towards this, Dinh and López-Permuth [17] studied algebraic structures of simple-root cyclic and negacyclic codes over finite commutative chain rings and their dual codes. In the same work, they also determined all
negacyclic codes of length $2^l$ over the ring $\mathbb{Z}_{2^m}$ of integers modulo $2^m$ and their dual codes, where $t \geq 1$ and $m \geq 2$ are integers. In a related work, Batoul et al. [3] proved that when $\lambda$ is an $n$th power of a unit in a finite commutative chain ring $R$, repeated-root $\lambda$-constacyclic codes of length $n$ over $R$ are equivalent to cyclic codes of the same length over $R$. Apart from this, many authors [1], [2], [5], [22], [36] investigated algebraic structures of linear and cyclic codes over the finite commutative chain ring $\mathbb{F}_p[v]/\langle v^2 \rangle$.

To describe the recent work, let $p$ be a prime, $s, m$ be positive integers, $\mathbb{F}_{p^m}$ be the finite field of order $p^m$, and let $\mathbb{F}_{p^m}[v]/\langle v^2 \rangle$ be the finite commutative chain ring with unity. Ding [15] determined all constacyclic codes of length $p^s$ over $\mathbb{F}_{p^m}[v]/\langle v^2 \rangle$ and their Hamming distances. Later, Chen et al. [14] and Liu and Xu [25] determined all constacyclic codes of length $2p^s$ over the ring $\mathbb{F}_{p^m}[v]/\langle v^2 \rangle$, where $p$ is an odd prime. Using a technique different from that employed in [14], [15], [25], Cao et al. [8] determined all $\alpha$-constacyclic codes of length $np^s$ over $\mathbb{F}_{p^m}[v]/\langle v^2 \rangle$ and their dual codes by writing a canonical form decomposition for each code, where $\alpha$ is a non-zero element of $\mathbb{F}_{p^m}$ and $n$ is a positive integer with $\gcd(p, n) = 1$. In a recent work, Zhao et al. [38] determined all $(\alpha + \beta v)$-constacyclic codes of length $np^s$ over $\mathbb{F}_{p^m}[v]/\langle v^2 \rangle$ and their dual codes, where $n$ is a positive integer coprime to $p$, and $\alpha, \beta$ are non-zero elements of $\mathbb{F}_{p^m}$. This completely solved the problem of determination of all constacyclic codes of length $np^s$ over $\mathbb{F}_{p^m}[v]/\langle v^2 \rangle$ and their dual codes, where $n$ is a positive integer coprime to $p$. In a recent work [34], we determined all repeated-root constacyclic codes of arbitrary lengths over the finite commutative chain ring $\mathbb{F}_{p^m}[u]/\langle u^2 \rangle$ of characteristic $p^2$ and cardinality $p^{2m}$, their sizes and their dual codes. In the same work, we also listed some isodual repeated-root constacyclic codes over $\mathbb{F}_{p^m}[u]/\langle u^2 \rangle$.

In a related work, Cao [7] established algebraic structures of all $(1 + aw)$-constacyclic codes of arbitrary lengths over a finite commutative chain ring $R$ with the maximal ideal as $\langle w \rangle$, where $a$ is a unit in $R$. Later, Dinh et al. [18] studied repeated-root $(\alpha + aw)$-constacyclic codes of length $p^s$ over a finite commutative chain ring $R$ with the maximal ideal as $\langle w \rangle$, where $p$ is a prime number, $s \geq 1$ is an integer and $\alpha, a$ are units in $R$. The results obtained in Dinh et al. [18] can also be obtained from the work of Cao [7] via the ring isomorphism from $R[x]/\langle x^t - 1 - aw^{-1}w \rangle$ onto $R[x]/\langle x^t - \text{textalpha} - aw \rangle$, denoted as $A(x) \mapsto A(\alpha_0^{-1} x)$ for each $A(x) \in R[x]/\langle x^t - 1 - aw^{-1}w \rangle$, where $\alpha = \alpha_0^p$ (such an element $\alpha_0$ always exists in $\mathbb{F}_{p^m}$). The constraint that $a$ is a unit in $R$ restricts their study to only a few special classes of repeated-root constacyclic codes over $R$. When $a$ is a unit in $R$, codes belonging to these special classes are direct sums of (principal) ideals of certain finite commutative chain rings. However, when $a$ is not a unit in $R$, there are repeated-root constacyclic codes over $R$, which are direct sums of non-principal ideals. In another related work, Sobhani [35] determined all $(\alpha + \gamma v^2)$-constacyclic codes of length $p^s$ over $\mathbb{F}_{p^m}[u]/\langle u^2 \rangle$ and their dual codes, where $\alpha, \gamma$ are non-zero elements of $\mathbb{F}_{p^m}$. For more related works, readers may refer to [9]–[13].

The main goal of this paper is to determine all repeated-root constacyclic codes of arbitrary lengths over the finite commutative chain ring $\mathbb{F}_{p^m}[u]/\langle u^2 \rangle$, their sizes and their dual codes, where $p$ is a prime and $m$ is a positive integer. Hamming distances, RT distances, RT weight distributions and ranks (i.e., cardinalities of minimal generating sets) are also determined for some repeated-root constacyclic codes over $\mathbb{F}_{p^m}[u]/\langle u^2 \rangle$. Some isodual and MDS codes over $\mathbb{F}_{p^m}[u]/\langle u^2 \rangle$ with respect to Hamming and RT metrics are also identified within this class of constacyclic codes.

This paper is organized as follows: In Section II, we state some basic definitions and results that are needed to derive our main results. In Section III, we determine all repeated-root constacyclic codes of arbitrary lengths over $\mathbb{F}_{p^m}[u]/\langle u^2 \rangle$, their dual codes and their sizes (Theorems 13–18). As an application, we also determine some isodual repeated-root constacyclic codes over $\mathbb{F}_{p^m}[u]/\langle u^2 \rangle$ (Corollaries 14–19). In Section IV, we determine Hamming distances, RT distances, RT weight distributions and ranks (i.e., cardinalities of minimal generating sets) of some repeated-root constacyclic codes over $\mathbb{F}_{p^m}[u]/\langle u^2 \rangle$ (Theorems 21, 23, 25, 26, 28, 30). We also list some MDS constacyclic codes over $\mathbb{F}_{p^m}[u]/\langle u^2 \rangle$ with respect to Hamming and RT metrics (Theorems 22, 24, 27 and 29). In Section V, we determine Hamming distances of all repeated-root constacyclic codes of length $2p^s$ over $\mathbb{F}_{p^m}[u]/\langle u^2 \rangle$ (Theorem 33). We also list all MDS repeated-root constacyclic codes of length $2p^s$ over $\mathbb{F}_{p^m}[u]/\langle u^2 \rangle$ with respect to the Hamming metric (Theorem 35). In Section VI, we mention a brief conclusion and discuss some interesting open problems in this direction.

II. SOME PRELIMINARIES

A commutative ring $R$ with unity is called (i) a local ring if it has a unique maximal ideal (consisting of all the non-units of $R$), and (ii) a chain ring if all its ideals form a chain with respect to the inclusion relation. Then the following result is well-known.

**Proposition 1** [17]: For a finite commutative ring $R$ with unity, the following statements are equivalent:

(a) $R$ is a local ring whose maximal ideal $M$ is principal, i.e., $M = \langle w \rangle$ for some $w \in R$.
(b) $R$ is a local principal ideal ring.
(c) $R$ is a chain ring and all its ideals are given by $\langle w^i \rangle$, $0 \leq i \leq e$, where $e$ is the nilpotency index of $w$. Furthermore, we have $|\langle w^i \rangle| = |R/(w)^{e-i}|$ for $0 \leq i \leq e$. (Throughout this paper, $|A|$ denotes the cardinality of the set $A$.)

Now let $R$ be a finite commutative ring with unity, and let $N$ be a positive integer. Let $R^N$ be the $R$-module consisting of all $N$-tuples over $R$. For a unit $\lambda \in R$, a $\lambda$-constacyclic code $C$ of length $N$ over $R$ is defined as an $R$-submodule of
Proof: Working in a similar manner as in Theorem 3.4 of Dinh [15], the desired result follows. □

Theorem 5 [27]: Let \( p \) be an odd prime, and let \( \omega \) be a non-zero square in \( \mathbb{F}_p^{\ast} \). Then there exists \( a_0 \in \mathbb{F}_p^{\ast} \) satisfying \( \omega = a_0^2 \). Further, \( a_0 \) is a square in \( \mathbb{F}_p^{\ast} \), i.e., there exists \( \xi \in \mathbb{F}_p^{\ast} \) such that \( \omega = \xi^2 \).

Now let \( C \) be a non-zero \( \omega \)-constacyclic code of length \( 2p^s \) over \( \mathbb{F}_p^{\ast} \). Then we have \( C = \langle (x + \xi)^{s_1}(x - \xi^{s_2}) \rangle \), where \( 0 \leq s_1, s_2 \leq p^s \).
When $v_1 \geq v_2$, the Hamming distance $d_H(C)$ of the code $C$ over $\mathbb{F}_{p^m}$ is given by
\[
d_H(C) = \begin{cases} 
1 & \text{if } v_1 = v_2 = 0; \\
2 & \text{if } v_1 = 0 \text{ and } 0 < v_2 \leq p^s; \\
\min((\ell + 2)p^k, 2(\ell + 1)p^k) & \text{if } p^s - p^k + (p^{s-k})^{\ell-1} + 1 \leq v_1 \leq p^s - p^{s-k} + (\ell + 1)p^{s-k} + p^s - p^{s-k} + \ell p^{s-k} - 1 \leq v_2 \leq p^s - p^{s-k} + (\ell + 1)p^{s-k} - 1 \text{ with } 0 \leq \ell, \ell_1 \leq p - 2, \\
& \text{and } 0 \leq k \leq s - 1. 
\end{cases}
\]

When $v_2 \geq v_1$, the Hamming distance $d_H(C)$ of the code $C$ over $\mathbb{F}_{p^m}$ is given by
\[
d_H(C) = \begin{cases} 
1 & \text{if } v_1 = v_2 = 0; \\
2 & \text{if } v_1 = 0 \text{ and } 0 < v_2 \leq p^s; \\
\min((\ell + 2)p^k, 2(\ell + 1)p^k) & \text{if } p^s - p^k + (p^{s-k})^{\ell-1} + 1 \leq v_1 \leq p^s - p^{s-k} + (\ell + 1)p^{s-k} + p^s - p^{s-k} + \ell p^{s-k} - 1 \leq v_2 \leq p^s - p^{s-k} + (\ell + 1)p^{s-k} - 1 \text{ with } 0 \leq \ell, \ell_1 \leq p - 2, \\
& \text{and } 0 \leq k \leq s - 1. 
\end{cases}
\]

Moreover, the code $C$ is an MDS code if and only if exactly one of the following conditions is satisfied:
- $v_1 = v_2 = 0$;
- $v_1 = 1$ and $v_2 = 0$;
- $v_1 = 0$ and $v_2 = 0$;
- $v_1 = p^s$ and $v_2 = p^s - 1$;
- $v_1 = p^s - 1$ and $v_2 = p^s$.

Theorem 6 [29]: Let $C$ be a linear code of length $N$ over $\mathcal{R}$. Then $\text{Tor}_2(C) = \{a \in \mathbb{F}_{p^m}^N : u^2 a \in C\}$ is a linear code of length $N$ over $\mathbb{F}_{p^m}$. Furthermore, we have $d_H(C) = d_H(\text{Tor}_2(C))$.

Next we proceed to study algebraic structures of all constacyclic codes of length $n = np^s$ over the ring $\mathcal{R} = \mathbb{F}_{p^m} + u\mathbb{F}_{p^m} + u^2\mathbb{F}_{p^m}$, where $u^2 = 0$, $p$ is a prime and $n, s, m$ are positive integers with $\gcd(n, p) = 1$.

III. CONSTACYCLIC CODES OF LENGTH $np^s$ OVER $\mathcal{R}$

Throughout this paper, let $p$ be a prime, and let $n, s, m$ be positive integers with $\gcd(n, p) = 1$. Let $\mathbb{F}_{p^m}$ be the finite field of order $p^m$, and let $\mathcal{R} = \mathbb{F}_{p^m}[u]/(u^3)$ be the finite commutative chain ring with unity. Let $\lambda = \alpha + \beta u + \gamma u^2$, where $\alpha, \beta, \gamma \in \mathbb{F}_{p^m}$ and $\alpha$ is non-zero. In this section, we shall provide a method to construct all $\lambda$-constacyclic codes of length $np^s$ over $\mathcal{R}$ for the purpose of error-detection and error-correction. We shall also determine their dual codes and the number of codewords in each code. Apart from this, we shall list some isodual constacyclic codes of length $np^s$ over $\mathcal{R}$. These results are useful in encoding and decoding these codes and in studying their error-detecting and error-correcting capabilities with respect to various communication channels.

To do this, we recall that a $\lambda$-constacyclic code of length $np^s$ over $\mathcal{R}$ is an ideal of the quotient ring $\mathcal{R}_\lambda = \mathcal{R}[x]/(x^{np^s} - \lambda)$. Moreover, by Lemma 7, there exists $\lambda_0' \in \mathbb{F}_{p^m}$ satisfying $\lambda_0' = \alpha$. Now let $x^{-\alpha} - \alpha_0 = f_1(x)f_2(x) \cdots f_s(x)$ be the irreducible factorization of $x^{-\alpha} - \alpha_0$ over $\mathbb{F}_{p^m}$, where $f_1(x), f_2(x), \ldots, f_s(x)$ are monic pairwise coprime polynomials over $\mathbb{F}_{p^m}$. In the following lemma, we factorize the polynomial $x^{np^s} - \lambda$ into pairwise coprime polynomials in $\mathcal{R}[x]$.

Lemma 7: There exist polynomials $g_1(x), g_2(x), \ldots, g_r(x), h_1(x), h_2(x), \ldots, h_r(x) \in \mathbb{F}_{p^m}[x]$ such that
\[
x^{np^s} - \lambda = \prod_{j=1}^{r} \left( f_j(x)^{p^s} + u g_j(x) + u^2 h_j(x) \right),
\]
where for $1 \leq j \leq r$,
- $\gcd(f_j(x), g_j(x)) = 1$ when $\beta \neq 0$.
- $g_j(x) = h_j(x) = 0$ when $\beta = \gamma = 0$.
- $g_j(x) = 0$ and $\gcd(f_j(x), h_j(x)) = 1$ in $\mathbb{F}_{p^m}[x]$ when $\beta = 0$ and $\gamma$ is non-zero.

Moreover, the polynomials $f_1(x)^{p^s} + u g_1(x) + u^2 h_1(x), f_2(x)^{p^s} + u g_2(x) + u^2 h_2(x), \ldots, f_r(x)^{p^s} + u g_r(x) + u^2 h_r(x)$ are pairwise coprime in $\mathcal{R}[x]$. This, by Chinese Remainder Theorem, implies that
\[
\mathcal{R}_\lambda \cong \bigoplus_{j=1}^{r} K_j,
\]
where $K_j = \mathcal{R}[x]/(k_j(x))$ for $1 \leq j \leq r$. Then we observe the following:

Proposition 8: (a) Let $C$ be a $\lambda$-constacyclic code of length $np^s$ over $\mathcal{R}$, i.e., an ideal of the ring $\mathcal{R}_\lambda$. Then $C = C_1 \oplus C_2 \oplus \cdots \oplus C_r$, where $C_j$ is an ideal of $K_j$ for $1 \leq j \leq r$.

(b) If $I_j$ is an ideal of $K_j$ for $1 \leq j \leq r$, then $I = I_1 \oplus I_2 \oplus \cdots \oplus I_r$ is an ideal of $\mathcal{R}_\lambda$, i.e., $I$ is a
λ-constacyclic code of length $np^s$ over $R$. Moreover, we have $|I| = |I_1||I_2|\cdots|I_r|$. 

Proof: Proof is trivial. □

Next if $C$ is a λ-constacyclic code of length $np^s$ over $R$, then its dual code $C^⊥$ is a λ-1-constacyclic code of length $np^s$ over $R$. This implies that $C^⊥$ is an ideal of the ring $R_{λ-1} = R[x]/(x^{np^s} - λ - 1)$. In order to determine $C^⊥$ more explicitly, we observe that $x^{np^s} - λ - 1 = -α^{-1}k^*_j(x)^s \cdots k^*_s(x)$. By applying Chinese Remainder Theorem again, we get $R_{λ-1} \cong \bigoplus_{j=1}^{r} \hat{K}_j$, where $\hat{K}_j = R[x]/(k^*_j(x))$ for $1 \leq j \leq r$.

Then we have the following:

Proposition 9: Let $C$ be a λ-constacyclic code of length $np^s$ over $R$, i.e., an ideal of the ring $R_{λ}$. If $C = C_1 \oplus C_2 \oplus \cdots \oplus C_r$ with $C_j$ an ideal of $K_j$ for each $j$, then the dual code $C^⊥$ of $C$ is given by $C^⊥ = C_1^⊥ \oplus C_2^⊥ \oplus \cdots \oplus C_r^⊥$, where $C_j^⊥ = \langle a_j(x) \in \hat{K}_j : a_j(x)k^*_j(x) = 0 \in \hat{K}_j \rangle$. for all $c_j(x) \in C_j$ is the orthogonal complement of $C_j$ for each $j$. Furthermore, $C^⊥$ is an ideal of $\hat{K}_j = R[x]/(k^*_j(x))$ for each $j$.

Proof: Proof is straightforward. □

In view of Propositions 8 and 9, we see that to determine all λ-constacyclic codes of length $np^s$ over $R$, their sizes and their dual codes, we need to determine all ideals of the ring $K_j$, their cardinalities and their orthogonal complements in $K_j$ for $1 \leq j \leq r$. To do so, throughout this paper, let $1 \leq j \leq r$ be elements of $I$. From now on, we shall represent elements of the rings $K_j$ and $\hat{K}_j$ (resp. $F_{np^s}[x]/(f_j(x)^{p^s})$) by their representatives in $R[x]$ (resp. $F_{np^s}[x]$) of degree less than $dp^s$, and we shall perform their addition and multiplication modulo $k_j(x)$ and $k_j^*(x)$ (resp. $f_j(x)^{p^s}$), respectively. To determine all ideals of the ring $K_j$, we make the following observation.

Lemma 10: Let $1 \leq j \leq r$ be fixed. In the ring $K_j$, the following hold.

(a) Any non-zero polynomial $g(x) \in F_{np^s}[x]$ satisfying $\gcd(g(x), f_j(x)) = 1$ is a unit in $K_j$. As a consequence, any non-zero polynomial in $F_{np^s}[x]$ of degree less than $d_j$ is a unit in $K_j$.

(b) $\langle f_j(x)^{p^s} \rangle = \langle u \rangle$ if $β ≠ 0$; $\langle u^2 \rangle$ if $β = 0$ and $γ ≠ 0$; $\langle 0 \rangle$ if $β = γ = 0$.

As a consequence, $f_j(x)$ is a nilpotent element of $K_j$. The nilpotency index of $f_j(x)$ is $3p^s$ when $β ≠ 0$, the nilpotency index of $f_j(x)$ is $2p^s$ when $β = 0$ and $γ ≠ 0$, while the nilpotency index of $f_j(x)$ is $p^s$ when $β = γ = 0$.

Proof: Proof is straightforward. □

Next for a positive integer $k$, let $P_k(F_{np^s}) = \{g(x) \in F_{np^s}[x] : \text{either } g(x) = 0 \text{ or } \deg g(x) < k\}$. Note that every element $a(x) \in K_j$ can be uniquely expressed as $a(x) = a_0(x) + ua_1(x) + u^2a_2(x)$, where $a_0(x), a_1(x), a_2(x) \in P_{dp^s}(F_{np^s})$. Further, by repeatedly applying the division algorithm in $F_{np^s}[x]$, for $ℓ \in \{0, 1, 2\}$, we can write $a_ℓ(x) = \sum_{i=0}^{p^s-1} A_i(a_ℓ(x))f_j(x)^i$, where $A_i(a_ℓ(x)) \in P_{d_ℓ}(F_{np^s})$ for $0 \leq i \leq p^s - 1$. That is, each element $a(x) \in K_j$ can be uniquely expressed as $a(x) = \sum_{i=0}^{p^s-1} A_i(a_ℓ(x))f_j(x)^i + \sum_{i=0}^{p^s-1} u A_i(a_1(x))f_j(x)^i + u^2 \sum_{i=0}^{p^s-1} A_i(a_2(x))f_j(x)^i$, where $A_i(a_ℓ(x)) \in \mathcal{P}_{d_ℓ}(F_{np^s})$ for each $i$ and $ℓ$. Now to determine cardinalities of all ideals of $K_j$, we observe the following:

Lemma 11: Let $1 \leq j \leq r$ be a fixed integer. For an ideal $I$ of $K_j$, let us define $\text{Tor}_0(I) = \{a_0(x) \in F_{np^s}[x]/(f_j(x)^{p^s}) : a_0(x) + u_0a_1(x) + u^2a_2(x) = 0 \in I\}$ for some $a_1(x), a_2(x) \in F_{np^s}[x]/(f_j(x)^{p^s})$, $\text{Tor}_1(I) = \{a_1(x) \in F_{np^s}[x]/(f_j(x)^{p^s}) : au_1(x) + u^2a_2(x) = 0 \in I\}$ for some $a_1(x) \in F_{np^s}[x]/(f_j(x)^{p^s})$ and $\text{Tor}_2(I) = \{a_2(x) \in F_{np^s}[x]/(f_j(x)^{p^s}) : u^2a_2(x) = 0 \in I\}$. Then $\text{Tor}_0(I), \text{Tor}_1(I)$ and $\text{Tor}_2(I)$ are ideals of $F_{np^s}[x]/(f_j(x)^{p^s})$. Moreover, we have $|I| = |\text{Tor}_0(I)||\text{Tor}_1(I)||\text{Tor}_2(I)|$.

Proof: Proof is trivial. □

To determine orthogonal complements of all ideals of $K_j$, we need the following lemma.

Lemma 12: Let $1 \leq j \leq r$ be a fixed integer. Let $I$ be an ideal of the ring $K_j$ with the orthogonal complement as $I^⊥$.

Then the following hold.

(a) $I^⊥$ is an ideal of $K_j$.

(b) $I^⊥ = \{a(x) \in K_j : a(x) \in \text{ann}(I)\} = \text{ann}(I)^*$. (c) If $I = \langle f(x), ug(x), u^2h(x) \rangle$, then we have $I^⊥ = \langle f^*(x), ug^*(x), u^2h^*(x) \rangle$.

(d) For non-zero $f(x), g(x) \in K_j$, let us define $(fg(x)) = f(x)g(x)$ and $(f + g(x)) = f(x) + g(x)$. If $(fg(x)) ≠ 0$, then we have $f^*(x)(g^*(x) = x^{-\deg f(x) + \deg g(x)} - deg(f(x))(g(x)^*)$. If $(f + g(x)) = 0$, then we have

$$ (f + g)^*(x) = \begin{cases} f^*(x) + x^{deg f(x) - deg g(x)}g^*(x) & \text{if } \deg f(x) > \deg g(x); \\ x^{-deg(f(x) - deg g(x))}(f^*(x) + g^*(x)) & \text{if } \deg f(x) = \deg g(x). \end{cases} $$

Proof: Proof is straightforward. □

From the above lemma, we see that to determine $I^⊥$, it is enough to determine $\text{ann}(I)$ for each ideal $I$ of $K_j$. Further, to write down all ideals of $K_j$, we see, by Lemma 11, that for each ideal $I$ of $K_j$, $\text{Tor}_0(I)$, $\text{Tor}_1(I)$ and $\text{Tor}_2(I)$ all are ideals of the ring $F_{np^s}[x]/(f_j(x)^{p^s})$, which is a finite commutative chain ring with the maximal ideal as $\langle f_j(x) \rangle$. Next by Proposition 1, we see that all the ideals of $F_{np^s}[x]/(f_j(x)^{p^s})$ are given by $\langle f_j(x) \rangle$ with $0 \leq i \leq p^s$ and that $|\langle f_j(x) \rangle| = p^{md_{d_j}/p^s}$ for each $i$. This implies that $\text{Tor}_0(I) = \langle f_j(x) \rangle$, $\text{Tor}_1(I) = \langle f_j(x)^p \rangle$ and $\text{Tor}_2(I) = \langle f_j(x)^{p^s} \rangle$ for some integers $a, b, c$ satisfying $0 \leq c \leq b \leq a \leq p^s$.

First of all, we shall consider the case $β ≠ 0$. Here we see that when $a_0 = μ^a$ for some $μ \in F_{np^s}$, each λ-constacyclic code of length $np^s$ over $R$ can be determined by using the results derived in Cao [7] and by applying the ring isomorphism from $R[x]/(x^{np^s} - 1 - α^{-1}βu - α^{-1}γu^2)$ onto $R[x]/(x^{np^s} - αβ - γu^2)$, defined as $(a(x) + αu_0 + βu_1 + γu^2) \mapsto a(μ^{-1}x)$. This isomorphism allows us to replace the action of $\lambda$ by $α^{-1}μ^{-1}$.
However, when $a_0$ (and hence $\alpha$) is not an $n$th power of an element in $\mathbb{F}_{p^n}$, the same technique can not be employed to determine all $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathcal{R}$. In fact, the problem of determination of all $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathcal{R}$ and their dual codes is not yet completely solved. Propositions 8 and 9 and the following theorem completely solves this problem when $\beta$ is non-zero.

**Theorem 13:** When $\beta \neq 0$, the following hold.

(a) All ideals of the ring $K_j$ are given by $\langle f_j(x)^j \rangle$, where $0 \leq j \leq 3p^s$. Furthermore, for $0 \leq j \leq 3p^s$, we have $|\langle f_j(x)^j \rangle| = p^{mj(3p^s-j)}$ and $\text{ann}(\langle f_j(x)^j \rangle) = \langle f_j(x)^{3p^s-j} \rangle$.

(b) When $kp^s \leq \ell \leq (k + 1)p^s$ with $k \in \{0, 1, 2\}$, the set $\{u^k f_j(x)^{\ell-kp^s}, u^k x f_j(x)^{\ell-kp^s}, \ldots, u^k x^d(k+1)p^s-\ell)f_j(x)^{\ell-kp^s} \} \cup \{u^{k+1}, u^{k+1}x, \ldots, u^{k+1}x^{d(k-p^s-1)} \}$ is a minimal generating set of the ideal $\langle f_j(x)^j \rangle$ when viewed as an $\mathcal{R}$-module.

**Proof:** Proof of part (a) is similar to that of Theorem 3.3 and Corollary 3.5 of Chen et al. [14], while part (b) is an easy exercise.

As a consequence of the above theorem, we deduce the following:

**Corollary 14:** Let $n \geq 1$ be an integer and $a_0 \in \mathbb{F}_{p^n}$ be such that the binomial $x^n - a_0$ is irreducible over $\mathbb{F}_{p^n}$. Let $\alpha = a_0^\beta$, and $\beta(\neq 0), \gamma \in \mathbb{F}_{p^n}$. Then there exists an isodual $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathcal{R}$ if and only if $p = 2$. Moreover, when $p = 2$, the ideal $(\langle x^n - a_0^\beta \rangle^{3}2^{-1})$ is the only isodual $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $2n^2$ over $\mathcal{R}$.

**Proof:** On taking $f_j(x) = x^n - a_0$ in Theorem 13, we see that all $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathcal{R}$ are given by $\langle (x^n - a_0)^\beta \rangle$, where $0 \leq \beta \leq 3p^s$. Furthermore, for $0 \leq \beta \leq 3p^s$, the code $\langle (x^n - a_0)^\beta \rangle$ has $p^{mn(3p^s-\beta)}$ elements and the annihilator of $\langle (x^n - a_0)^\beta \rangle$ is given by $\langle (x^n - a_0)^{\beta(3p^s-\beta)} \rangle$. Next we see that if the code $\mathcal{C} = \langle (x^n - a_0)^\beta \rangle$ is isodual, then we must have $|\mathcal{C}| = |\mathcal{C}^\perp|$. This gives $p^{mn(3p^s-\beta)} = p^{mn\beta}$. This implies that $3p^s = 2\ell$, which holds if and only if $p = 2$. So when $p$ is an odd prime, there does not exist any isodual $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathcal{R}$. When $p = 2$, we get $\ell = 3 \cdot 2^{-1}$. On the other hand, when $p = 2$, we observe that $(\langle x^n - a_0^\beta \rangle^{3}2^{-1})$ is an isodual $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $n^2$ over $\mathcal{R}$, which completes the proof.

**Remark 15:** By Theorem 3.75 of [26], we see that the binomial $x^n - a_0$ is irreducible over $\mathbb{F}_{p^n}$ if and only if the following two conditions are satisfied: (i) each prime divisor of $n$ divides the multiplicative order $e$ of $a_0$, but not $(p^m-1)/e$ and (ii) $p^m \equiv 1 \pmod{n}$ if $|n| = 0 \pmod{4}$.

In the following theorem, we consider the case $\beta = \gamma = 0$, and we determine all non-trivial ideals of the ring $K_j$, their cardinalities, their annihilators and their minimal generating sets.

**Theorem 16:** Let $\beta = \gamma = 0$, and let $\mathcal{I}$ be a non-trivial ideal of the ring $K_j$ with $\text{Tor}_0(\mathcal{I}) = \langle f_j(x)^j \rangle$, $\text{Tor}_1(\mathcal{I}) = \langle f_j(x)^{j} \rangle$ and $\text{Tor}_2(\mathcal{I}) = \langle f_j(x)^j \rangle$ for some integers $a, b, c$ satisfying $0 \leq c \leq b \leq a \leq p^s$. Suppose that $B_i(x), C_i(x), Q_i(x), W_i(x)$ run over $\mathcal{P}_d(\mathbb{F}_{p^n})$ for each relevant $i, k, \ell$ and $e$. Then the following hold.

- **Type I:** When $a = b = p^s$, we have $\mathcal{I} = \langle u^2 f_j(x)^j \rangle$, where $c < p^s$. Moreover, we have $|\mathcal{I}| = p^{md(p^s-c)}$, $\text{ann}(\mathcal{I}) = \langle f_j(x)^{p^s-c}, u \rangle$, and the set $\{u^2 f_j(x)^j, u^2 x f_j(x)^j, \ldots, u^2 x^{d(p^s-d_j-c-1)} f_j(x)^j \}$ is a minimal generating set of the ideal $\langle f_j(x)^j \rangle$ when viewed as an $\mathcal{R}$-module.

- **Type II:** When $a = p^s$ and $b < p^s$, we have $\mathcal{I} = \langle u f_j(x)^b + u^2 f_j(x)^j G(x), u^2 f_j(x)^j \rangle$, where $\max(0, c - b - p^s) \leq t < \epsilon$ if $G(x) \neq 0$ and $G(x)$ is either 0 or a unit in $K_j$ of the form $\sum_{i=0}^{c-t-1} B_i(x)f_j(x)^i$. Moreover, we have $|\mathcal{I}| = p^{md(2p^s-b-c)}$, $\text{ann}(\mathcal{I}) = \langle f_j(x)^{p^s-c} - u f_j(x)^{p^s-c}, \epsilon \rangle$, and the set $\{u f_j(x)^b + u^2 f_j(x)^j G(x), u x f_j(x)^j G(x), \ldots, x^{d(p^s-d_j-b-1)}(uf_j(x)^b + u^2 f_j(x)^j G(x)) \}$ $\cup \{u^2 f_j(x)^j, u^2 x f_j(x)^j, \ldots, u^2 x^{d_j(b-1)-d_j-1} f_j(x)^j \}$ is a minimal generating set of the ideal $\mathcal{I}$ when viewed as an $\mathcal{R}$-module.

- **Type III:** When $a < p^s$, we have $\mathcal{I} = \langle f_j(x)^b + u f_j(x)^j D_1(x), u^2 f_j(x)^j D_2(x), u^2 f_j(x)^j V(x), u^2 f_j(x)^j \rangle$, where $\max(0, a + b - p^s) \leq t \leq c$ if $D_1(x) \neq 0$, $0 \leq t < c$ if $D_2(x) \neq 0$, $\max(0, b + c - p^s) \leq \theta < c$ if $V(x) \neq 0$. $D_1(x)$ is either 0 or a unit in $K_j$, and $D_2(x)$ is either 0 or a unit in $K_j$ of the form $\sum_{k=0}^{c-\theta-1} C_k(x)f_j(x)^k$. Furthermore, we have $u^2(f_j(x)^{p^s-a+t-1-b+\theta} V(x)D_1(x)) = \langle u^2 f_j(x)^j \rangle$, i.e., there exists $A(x) \in \mathbb{F}_{p^n}[x]/\langle f_j(x)^j \rangle$ such that $u^2(f_j(x)^{p^s-a+t-1-b+\theta} V(x)D_1(x)) = u^2 f_j(x)^j A(x)$. 

\[ \text{VOLUME 8, 2020} \]
Moreover, we have

\[ |I| = p^{md/(3p^t-a-b-c)}, \]

the annihilator of \( I \) is given by

\[
\text{ann}(I) = (f_j(x)^{p^t-c} - uf_j(x)^{p^t-c+a-b}V(x) + u^2 f_j(x)^a - u^2 f_j(x)^a + t D_1(x), u^2 f_j(x)^{p^t-a}),
\]

and the set

\[
\{F_1(x), xF_1(x), \ldots, x^{p^t-a-1}F_1(x) \} \cup \{F_2(x), xF_2(x), \ldots, x^{p^t-a-b-1}F_2(x) \} \cup \{u^2 f_j(x)^c, u^2 x f_j(x)^c, \ldots, u^2 x^{p^t-a-b-1} f_j(x)^c \}
\]
is a minimal generating set of the ideal \( I \) when viewed as an \( R \)-module, where \( F_1(x) = f_j(x)^{p^t} + u f_j(x)^{p^t} D_1(x) + u^2 f_j(x)^2 D_2(x) \) and \( F_2(x) = uf_j(x)^{p^t} + u^2 f_j(x)^2 V(x). \)

\textbf{Proof:} As \( I \) is a non-trivial ideal of \( K_j \), we note that either \( a = 0 \) or \( a = b = c = p^t \) hold. Further, by Lemma 11, we have \( |I| = p^{md/(3p^t-a-b-c)}. \) Now to write down all such non-trivial ideals of \( K_j \) and to determine their annihilators, we shall distinguish the following three cases:

\( i \) \hspace{1em} When \( a = b = p^t \), we have \( I \subseteq \langle u \rangle. \) In this case, we have \( 0 \leq c < p^t. \) Here we observe that \( I = \langle u^2 f_j(x)^c \rangle. \) Now to find \( \text{ann}(I), \) we consider the ideal \( B_1 = \langle f_j(x)^{p^t-c}, u, u^2 \rangle, \) and we see that \( B_1 \subseteq \text{ann}(I) \) and that \( |B_1| = p^{md/(2p^t+a)}. \) As

\[
p^{md/(p^t-c)} = |I| = \frac{|K_j|}{|\text{ann}(I)|} \leq \frac{p^{3md/p^t}}{|B_1|} = p^{md/(p^t-c)},
\]

we get \( \text{ann}(I) = B_1 = \langle f_j(x)^{p^t-c}, u, u^2 \rangle. \)

\( ii \) \hspace{1em} When \( a = p^t \) and \( b < p^t, \) we have \( I \subseteq \langle u \rangle \) and \( I \not\subseteq \langle u \rangle. \) Here we observe that

\[ I = \langle uf_j(x)^{p^t} + u^2 r(x), u^2 f_j(x)^c \rangle \]

for some \( r(x) \in K_j. \) Let us write \( u^2 r(x) = u^2 \sum_{i=0}^{p^t-1} G_i(x) f_j(x)^i \), where \( G_i(x) \in \mathcal{P}_d(F_{p^t}) \) for \( 0 \leq i \leq p^t - 1. \) Note that for all \( i \geq c, \) we have \( u^2 f_j(x)^i = u^2 f_j(x)^i f_j(x)^{-c} \in I, \) which implies that

\[ I = \langle uf_j(x)^{p^t} + u^2 \sum_{i=0}^{p^t-1} G_i(x) f_j(x)^i, u^2 f_j(x)^c \rangle. \]

If \( u^2 \sum_{i=0}^{p^t-1} G_i(x) f_j(x)^i \neq 0 \) in \( K_j, \) then choose the smallest integer \( t (0 \leq t < c) \) satisfying \( G_t(x) \neq 0, \)
which gives \( u^2 \sum_{i=0}^{c-1} G_i(x) f_j(x)^i = u^2 f_j(x)^c G(x), \)
where \( G(x) = \sum_{i=0}^{c-1} G_i(x) f_j(x)^i \) is a unit in \( K_j. \)

On the other hand, when \( u^2 \sum_{i=0}^{p^t-1} G_i(x) f_j(x)^i = 0 \) in \( K_j, \) let us choose \( G(x) = 0. \) From this, it follows that

\[ I = \langle uf_j(x)^{p^t} + u^2 f_j(x)^c V(x) \rangle. \]

Finally, further, as \( f_j(x)^{p^t-b} \cdot \langle uf_j(x)^{p^t-b+c} \rangle \subseteq \langle uf_j(x)^{p^t-b+c} \rangle \), we must have \( p^t-b+c \geq 0 \) when \( G(x) \neq 0. \) Moreover, let \( B_2 \in \langle f_j(x)^{p^t-b} - uf_j(x)^{p^t-b+c} \rangle, \)
which gives \( uf_j(x)^{p^t-b+c} \in I, \) we observe that \( B_2 \subseteq \text{ann}(I) \) and \( |B_2| = p^{md/(p^t+b+c)}. \)

Since \( p^{md/(p^t-b-c)} = |I| = \frac{|K_j|}{|\text{ann}(I)|} \leq \frac{p^{3md/p^t}}{|B_2|} \leq p^{md/(p^t+b+c)}, \)
we obtain \( |\text{ann}(I)| = |B_2| = p^{md/(p^t+b+c)}. \) This implies that

\[ \text{ann}(I) = B_2 = \langle f_j(x)^{p^t-b} - uf_j(x)^{p^t-b+c} \rangle, \]

for some \( r_1(x), r_2(x), q(x) \in K_j. \) Further, working as in the previous case, one can show that

\[ I = \langle f_j(x)^a + uf_j(x)^i D_1(x) + u^2 f_j(x)^c D_2(x), uf_j(x)^b + u^2 f_j(x)^c V(x), u^2 f_j(x)^c \rangle, \]

where \( D_1(x) \) is either 0 or a unit in \( K_j \) of the form \( \sum_{i=1}^{b-1} A_i(x) f_j(x)^{p^t-i} \) and \( D_2(x) \) is either 0 or a unit in \( K_j \)
of the form \( \sum_{k=t}^{c-1} B_k(x)f_j(x)^{p^t-k-t} \) and \( V(x) \) is either 0 or a unit in \( K_j \) of the form \( \sum_{i=0}^{c-1} W_i(x) f_j(x)^{-i} \) with \( A_i(x), B_k(x), W_i(x) \in K_j \) for each \( c, k \) and \( i. \)
In order to determine \( \text{ann}(I), \) we first observe that \( uf_j(x)^{p^t-a+b} D_1(x) + u^2 f_j(x)^{p^t-a+b+c} D_2(x) \in I, \)
which implies that \( p^t-a+b+c \geq 0 \) when \( D_1(x) \neq 0. \) Next we see that \( f_j(x)^{p^t-b} \cdot \langle uf_j(x)^{p^t-b+c} \rangle \subseteq \langle uf_j(x)^{p^t-b+c} \rangle \), which gives \( p^t-b+c \geq 0 \) when \( V(x) \neq 0. \)
Moreover, as \( uf_j(x)^a + u^2 f_j(x)^c V(x) \in I \) and \( f_j(x)^{p^t-b} \cdot \langle uf_j(x)^{p^t-b+c} \rangle \subseteq \langle uf_j(x)^{p^t-b+c} \rangle \), we note that \( u^2 f_j(x)^c D_1(x) - f_j(x)^{a-b+b+c} V(x) \in I, \)
which implies that

\[ u^2 f_j(x)^c D_1(x) = f_j(x)^{a-b+b+c} V(x) \in \langle u^2 f_j(x)^c \rangle. \]
From this, we obtain $u^2 f_1(x)^{p^2 - c} [f_1(x)^4 D_1(x) - f_1(x)^{p^2-b+\theta} V(x)] = 0$. Further, we see that

$$uf_j(x)^{p^2-a+1+t} D_1(x) + u^2 f_j(x)^{p^2-a+1+2t} D_2(x) \in \mathcal{I}$$

can be rewritten as

$$f_j(x)^{p^2-a+1-t} D_1(x) [uf_j(x)^{b} + u^2 f_j(x)^{\theta} V(x)] - u^2 f_j(x)^{p^2-a+1+bt} D_1(x) V(x) + u^2 f_j(x)^{p^2-a+1+2t} D_2(x),$$

which implies that

$$u^2 f_j(x)^{p^2-a+1+b+\theta} D_1(x) V(x) - f_j(x)^{p^2-a+1+2t} D_2(x) \in \mathcal{I}.$$ 

This further implies that

$$u^2 f_j(x)^{p^2-a+1-b+\theta} D_1(x) V(x) - f_j(x)^{p^2-a+1+2t} D_2(x) \in \{u^2 f_j(x)^t\}.$$ 

Let us write $u^2 f_j(x)^{p^2-a+1-b+\theta} D_1(x) V(x) - f_j(x)^{p^2-a+1+2t} D_2(x) = u^2 f_j(x)^t A(x)$, where $A(x) \in \mathbb{F}_{p^n}[x]/(f_j(x)^t)$.

Next consider the ideal

$$B_3 = \{f_j(x)^{p^2-c} - u^2 f_j(x)^{p^2-c+\theta} V(x) + u^2 A(x), u^2 f_j(x)^{p^2-b} - u^2 f_j(x)^{p^2-a+1-b} D_1(x), u^2 f_j(x)^{p^2-a}\}.$$ 

Here we note that $|B_3| \geq p^{|\mathcal{J}|} (a+b+c)$ and $B_3 \subseteq \text{ann}(\mathcal{I})$. Further, as

$$p^{|\mathcal{J}|} (a+b+c) \leq p^{3|\mathcal{J}|} (a+b+c),$$

we get $|\text{ann}(\mathcal{I})| = |B_3| = p^{md(a+b+c)}$ and

$$|\text{ann}(\mathcal{I})| = B_3.$$ 

The determination of minimal generating sets of non-trivial ideals of $K_j$ is a straightforward exercise.

In the following corollary, we obtain some isodual $\alpha$-constacyclic codes of length $np^n$ over $\mathcal{R}$ when the binomial $x^n - \alpha_0$ is irreducible over $\mathbb{F}_{p^n}$.

**Corollary 17:** Let $n \geq 1$ be an integer and $\alpha_0 \in \mathbb{F}_{p^n} \setminus \{0\}$ be such that the binomial $x^n - \alpha_0$ is irreducible over $\mathbb{F}_{p^n}$. Let $\alpha = \alpha_0^p$. Following the same notations as in Theorem 16, we have the following:

(a) There does not exist any isodual $\alpha$-constacyclic code of Type I over $\mathcal{R}$.

(b) There exists an isodual $\alpha$-constacyclic code of Type II over $\mathcal{R}$ if and only if $p = 2$. In fact, when $p = 2$, the code $\langle x^n - \alpha_0 \rangle^{2r-1}, u^2 \rangle$ is the only isodual $\alpha$-constacyclic code of Type II over $\mathcal{R}$.

(c) There exists an isodual $\alpha$-constacyclic code of Type III over $\mathcal{R}$ if and only if $p = 2$. Moreover, when $p = 2$, the codes $C = \langle x^n - \alpha_0 \rangle^{2r-1}, u^2 \rangle$ satisfies $C = \text{ann}(C)$, from which part (c) follows.

In the following theorem, we consider the case $\beta = 0$ and $\gamma \neq 0$, and we determine all non-trivial ideals of the ring $K_j$, their orthogonal complements, their cardinalities and their minimal generating sets.

**Theorem 18:** Let $\beta = 0$ and $\gamma$ be a non-zero element of $\mathbb{F}_{p^n}$. Let $I$ be a non-trivial ideal of the ring $K_j$ with $\text{Tor}_0(I) = (f_j(x)^t \rangle, \text{Tor}_1(I) = (f_j(x)^t \rangle$ and $\text{Tor}_2(I) = (f_j(x)^t \rangle$ for some integers $a, b, c$ satisfying $0 \leq a \leq b \leq a \leq p^t$. Suppose that $B_1(x), C_0(x), Q_0(x), W_1(x)$ run over $\mathcal{P}_1(\mathbb{F}_{p^n})$ for each relevant $i, k, \ell$ and $e$. Then the following hold:

- **Type I:** When $a = b = p^t$, we have $I \subseteq (u^2 f_j(x)^t \rangle,$
where $0 \leq c < p^\beta$. Furthermore, we have

$$|\mathcal{I}| = p^{md(p^\beta-c)}, \quad \text{ann}(\mathcal{I}) = \langle f_j(x)^{p^\beta-c}, u \rangle$$

and the set

$$\{u^2 f_j(x)^{\alpha}, u^2 x f_j(x)^{\alpha}, \ldots, u^2 x^{dp^\beta-dc-1} f_j(x)^{\alpha}\}$$

is a minimal generating set of the ideal $\mathcal{I}$ when viewed as an $R$-module.

**Type II:** When $a = p^\beta$ and $b < p^\beta$, we have

$$|\mathcal{I}| = \langle uf_j(x)^{\alpha} + u^2 f_j(x)^{\alpha} G(x), u^2 f_j(x)^{\alpha}\rangle,$$

where $\max\{0, c + b - p^\beta\} \leq t < c$ if $G(x) \neq 0$ and $G(x)$ is either 0 or a unit in $K_j$ of the form $\sum_{i=0}^{m-1} B_i(x)f_j(x)^i$. Furthermore, we have

$$\text{ann}(\mathcal{I}) = \langle f_j(x)^{p^\beta-c} - uf_j(x)^{p^\beta-c+1-b} G(x), uf_j(x)^{p^\beta-b}, u^2 \rangle,$$

and the set

$$\{uf_j(x)^{\alpha} + u^2 f_j(x)^{\alpha} G(x), uf_j(x)^{\alpha} + u^2 f_j(x)^{\alpha} G(x), \ldots, x^{dp^\beta-db-1} uf_j(x)^{\alpha} + u^2 f_j(x)^{\alpha} G(x)\}$$

$$\cup \{u^2 f_j(x)^{\alpha}, u^2 x f_j(x)^{\alpha}, \ldots, u^2 x^{db-db-dc-1} f_j(x)^{\alpha}\}$$

is a minimal generating set of the ideal $\mathcal{I}$ when viewed as an $R$-module.

**Type III:** When $a < p^\beta$, we have

$$|\mathcal{I}| = \langle uf_j(x)^{\alpha} + uf_j(x)^{\alpha} D_1(x) + u^2 f_j(x)^{\alpha} D_2(x), uf_j(x)^{\alpha} + u^2 f_j(x)^{\alpha} V(x), u^2 f_j(x)^{\alpha}\rangle,$$

where $\max\{0, a + b - p^\beta\} \leq t < b$ if $D_1(x) \neq 0$, $0 \leq t_2 < c$ if $D_2(x) \neq 0$, $N_{x \to a} = b + c - p^\beta \geq 0$, and $V(x)$ is either 0 or a unit in $K_j$ of the form

$$\sum_{k=0}^{c-t_2-1} C_k(x)f_j(x)^k; \quad D_2(x) = \text{either 0 or a unit in } K_j\text{ of the form}$$

$$\sum_{k=0}^{c-1} \sum_{l=0}^{c-2 \cdot g-1} Q_{k,l}(x)f_j(x)^l\text{ and } V(x) = \text{either 0 or a unit in } K_j\text{ of the form}$$

$$\sum_{l=0}^{c-2 \cdot g-1} W_{l}(x)f_j(x)^l.$$ Further, we have

$$u^2(h_j(x) + uf_j(x)^{p^\beta-a+t_1-b} V(x)D_1(x)) - f_j(x)^{p^\beta-a+t_2} D_2(x) \in \langle u^2 f_j(x)^{\alpha}\rangle,$$

i.e., there exists $B(x) \in \mathbb{F}_{p^m}[x] / \langle f_j(x)^{\alpha}\rangle$ such that

$$u^2(h_j(x) + uf_j(x)^{p^\beta-a+t_1-b} V(x)D_1(x) - f_j(x)^{p^\beta-a+t_2} D_2(x)) = u^2 f_j(x)^{\alpha} B(x).$$

Moreover, we have

$$|\mathcal{I}| = p^{md(3p^\beta-a-b-c)},$$

the annihilator of $\mathcal{I}$ is given by

$$\text{ann}(\mathcal{I}) = \langle f_j(x)^{p^\beta-c} - uf_j(x)^{p^\beta-c+b} V(x)\rangle$$

$$+ u^2 B(x), uf_j(x)^{p^\beta-b} - u^2 f_j(x)^{p^\beta-a+t_1-b} D_1(x),$$

and the set

$$\{F_1(x), xF_2(x), \ldots, x^{dp^\beta-dc-1} F_1(x)\} \cup \{F_2(x), x^F_1(x), \ldots, x^{dp^\beta-dc-1} F_1(x)\}$$

is a minimal generating set of the ideal $\mathcal{I}$ when viewed as an $R$-module, where $F_1(x) = f_j(x)^{\alpha} + uf_j(x)^{\alpha} D_1(x) + u^2 f_j(x)^{\alpha} D_2(x)$ and $F_2(x) = uf_j(x)^{\alpha} + u^2 f_j(x)^{\alpha} V(x)$.

**Proof:** Working as in Theorem 16 and by applying Lemmas 10(c) and 11, the desired result follows.

In the following corollary, we list some isodual $(\alpha + \gamma u^2)$-constacyclic codes of length $n p^\beta$ over $\mathcal{R}$ when $\gamma \neq 0$ and the binomial $x^n - \alpha_0$ is irreducible over $\mathbb{F}_{p^m}$.

**Corollary 19:** Let $n \geq 1$ be an integer and $\alpha_0 \in \mathbb{F}_{p^m} \setminus \{0\}$ be such that the binomial $x^n - \alpha_0$ is irreducible over $\mathbb{F}_{p^m}$. Let $\alpha = \alpha_0^\gamma \in \mathbb{F}_{p^m}$, and let $\gamma$ be a non-zero element of $\mathbb{F}_{p^m}$. Following the same notations as in Theorem 18, we have the following:

(a) There does not exist any isodual $(\alpha + \gamma u^2)$-constacyclic code of Type I over $\mathcal{R}$.

(b) There exists an isodual $(\alpha + \gamma u^2)$-constacyclic code of Type II over $\mathcal{R}$ if and only if $p = 2$. Furthermore, when $p = 2$, the code $(u(x^n - \alpha_0)^2 - \gamma, u^n)$ is the only isodual $(\alpha + \gamma u^2)$-constacyclic code of Type II over $\mathcal{R}$.

(c) There exists an isodual $(\alpha + \gamma u^2)$-constacyclic code of Type III over $\mathcal{R}$ if and only if $p = 2$. Furthermore, when $p = 2$, the codes $C = \langle (x^n - \alpha_0)^2 + u(x^n - \alpha_0)^{2-\gamma} + u^2(x^n - \alpha_0)^2 D_2(x), u(x^n - \alpha_0)^{2-\gamma} + u^2 \gamma^{2-\alpha}, u^2(x^n - \alpha_0)^{2-\gamma}, \rangle$ are isodual $(\alpha + \gamma u^2)$-constacyclic codes of Type III over $\mathcal{R}$.

**Proof:** Working in a similar manner as in Corollary 17 and by applying Theorem 18, the desired result follows.

**IV. RANKS, HAMMING DISTANCES, RT DISTANCES AND RT WEIGHT DISTRIBUTIONS**

Let $\alpha, \beta, \gamma \in \mathbb{F}_{p^m}$ be such that $\alpha$ is non-zero. By Lemma 3(b), we see that there exists $\alpha_0 \in \mathbb{F}_{p^m}$ such that $\alpha = \alpha_0^\gamma$. Throughout this section, we assume that $n \geq 1$ is an integer and $\alpha_0 \in \mathbb{F}_{p^m} \setminus \{0\}$ is such that the binomial $x^n - \alpha_0$ is irreducible over $\mathbb{F}_{p^m}$. In this section, we shall determine ranks, Hamming distances, RT distances and RT weight distributions of all $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $n p^\beta$ over $\mathcal{R}$. We shall also list all MDS $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $n p^\beta$ over $\mathcal{R}$ with respect to the Hamming and RT metrics.

In the following theorem, ranks of all non-zero $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $n p^\beta$ over $\mathcal{R}$ are determined.

**Theorem 20:** The following hold.

(a) Let $\beta \in \mathbb{F}_{p^m} \setminus \{0\}$, and let $C = \langle (x^n - \alpha_0)^a \rangle$ be an $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $n p^\beta$ over $\mathcal{R}$, where $0 \leq v \leq 5 p^\beta - 1$. Then the rank of $C$ is given by

$$\text{rank}(C) = \begin{cases} n p^\beta & \text{if } 0 \leq v \leq 2 p^\beta - 1; \\
\text{or } (3 p^\beta - v) & \text{if } 2 p^\beta \leq v \leq 3 p^\beta - 1. \end{cases}$$
(b) Let $C$ be an $(\alpha + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathcal{R}$ with $\text{Tor}_3(C) = \langle (x^n - \alpha_0)^{v_1} \rangle$, where $0 \leq c \leq p^s - 1$. Then we have $\text{rank}(C) = np^s - nc$.

Proof: It follows immediately from Theorems 13(b), 16 and 18.

In the following theorem, Hamming distances of all non-zero $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathcal{R}$ are determined when $\beta$ is non-zero.

Theorem 21: Let $\beta \in \mathbb{F}_{p^s} \setminus \{0\}$, and let $C = \langle (x^n - \alpha_0)^v \rangle$ be an $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathcal{R}$, where $0 \leq v \leq 3p^s - 1$. Then with respect to the Hamming metric, the following hold.

(a) When $0 \leq v \leq 2p^s$, the code $C$ is an $[np^s, np^s, 1]$-code over $\mathcal{R}$.
(b) When $2p^s + 1 \leq v \leq 3p^s - 1$, the code $C$ is an $[np^s, n(3p^s - v), d_H(C)]$-code over $\mathcal{R}$, where

$$d_H(C) = \begin{cases} \ell + 2 & \text{if } 2p^s + \ell p^{s-1} + 1 \leq v \leq 2p^s + (\ell + 1)p^{s-1} \text{ with } 0 \leq \ell \leq p - 2; \\
(\ell + 1)p^k & \text{if } 3p^s - p^k - (i-1)p^{s-1} - 1 \leq v \leq 3p^s - p^k - ip^{s-1} - 1 \text{ with } 1 \leq i \leq p - 1 \text{ and } 1 \leq k \leq s - 1. \end{cases}$$

Proof: The Hamming distance of the code $C$ can be determined by applying Theorems 4 and 6, while Theorem 20(a) gives the rank of the code $C$. □

In the following theorem, we show that there does not exist any non-trivial MDS $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathcal{R}$ when $\beta \neq 0$.

Theorem 22: Let $\beta \in \mathbb{F}_{p^s} \setminus \{0\}$. With respect to the Hamming metric, the code $C = \langle 1 \rangle$ is the only MDS $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathcal{R}$.

Proof: Let $C$ be a non-zero $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathcal{R}$. Then by Theorem 13, we see that $C = \langle (x^n - \alpha_0)^v \rangle$, where $0 \leq v \leq 3p^s - 1$. By Theorem 13 again, we see that $|C| = p^{mn(3p^s-v)}$.

Now by (1), the code $C$ is MDS if and only if $p^{mn(3p^s-v)} = |C| = p^{3mn(p^s-d_H(C)+1)}$, which holds if and only if

$$nv = 3d_H(C) - 1.$$  \hspace{1cm} (2)

When $0 \leq v \leq 2p^s$, we see, by Theorem 21, that $d_H(C) = 1$. This, by (2), implies that the code $C$ is MDS if and only if $v = 0$.

Next let $2p^s + 1 \leq v \leq 3p^s - 1$. Here working as in Theorem 21, we see that $d_H(C)$ is equal to the Hamming distance of the $\alpha$-constacyclic code $D = \langle (x^n - \alpha_0)^v - 2p^s \rangle$ of length $np^s$ over $\mathbb{F}_{p^s}$. Proposition 1, we see that $|D| = p^{mn(p^s-v)+2p^s}$. By (1), we have $|D| \leq p^{mn(p^s-v)+d_H(D)+1}$. This implies that $nv = 3d_H(C) - 1$. This, and using the fact that $np^s \geq d_H(C) > d_H(C) - 1$, we get $nv > 3d_H(C) - 1$. This, by (2), implies that the code $C$ is not MDS when $2p^s + 1 \leq v \leq 3p^s - 1$.

This shows that $C = \langle 1 \rangle$ is the only MDS $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathcal{R}$ with respect to the Hamming metric. □

In the following theorem, we determine RT distances of all non-zero $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathcal{R}$ when $\beta$ is non-zero.

Theorem 23: Let $\beta \in \mathbb{F}_{p^s} \setminus \{0\}$, and let $C = \langle (x^n - \alpha_0)^v \rangle$ be an $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathcal{R}$, where $0 \leq v \leq 3p^s - 1$. With respect to the RT metric, the following hold.

(a) When $0 \leq v \leq 2p^s$, the code $C$ is an $[np^s, np^s, 1]$-code over $\mathcal{R}$.
(b) When $2p^s + 1 \leq v \leq 3p^s - 1$, the code $C$ is an $[np^s, n(3p^s - v), nv - 2np^s + 1]$-code over $\mathcal{R}$.

Proof: By Lemma 10(b), we have $\langle (x^n - \alpha_0)^v \rangle = \langle u \rangle$, which implies that $u^{2n} = \langle (x^n - \alpha_0)^v \rangle$ for $1 \leq v \leq 2p^s$. This implies that $d_{RT}(C) = 1$ for $1 \leq v \leq 2p^s$.

Next for $2p^s + 1 \leq v \leq 3p^s - 1$, we note that $C = \langle (x^n - \alpha_0)^v \rangle = \langle u^2(x^n - \alpha_0)^{v-2p^s} \rangle = \langle u^2(x^n - \alpha_0)^{v-2p^s} f(x) : f(x) \in \mathbb{F}_{p^s}[x] \rangle$. From this, it follows that $w_{RT}(Q(x)) = w_{RT}(u^2(x^n - \alpha_0)^{v-2p^s}) = nv - 2np^s + 1$ for each $Q(x) \in C \setminus \{0\}$. Moreover, we see that $w_{RT}(u^2(x^n - \alpha_0)^{v-2p^s}) = w_{RT}(u^2(x^n - \alpha_0)^{v-2p^s}) + nv - 2np^s + 1$, which gives $d_{RT}(C) = nv - 2np^s + 1$.

From this and by Theorem 20(a), we get the desired result. □

In the following theorem, we show that there does not exist any non-trivial MDS $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathcal{R}$ with respect to the RT metric when $\beta \neq 0$.

Theorem 24: Let $\beta \in \mathbb{F}_{p^s} \setminus \{0\}$. Then the code $C = \langle 1 \rangle$ is the only MDS $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathcal{R}$ with respect to the RT metric.

Proof: Let $C$ be a non-zero $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathcal{R}$. Then by Theorem 13, we have $C = \langle (x^n - \alpha_0)^v \rangle$, where $0 \leq v \leq 3p^s - 1$. By Theorem 13 again, we see that $|C| = p^{mn(3p^s-v)}$. Further, the code $C$ is MDS with respect to the RT metric if and only if $p^{mn(3p^s-v)} = |C| = p^{3mn(p^s-d_{RT}(C)+1)}$, which holds if and only if

$$nv = 3d_{RT}(C) - 1.$$  \hspace{1cm} (3)

Now for $0 \leq v \leq 2p^s$, by Theorem 23, we see that $d_{RT}(C) = 1$. By (3), we note that the code $C$ is MDS if and only if $v = 0$.

On the other hand, when $2p^s + 1 \leq v \leq 3p^s - 1$, by Theorem 23, we see that $d_{RT}(C) = nv - 2np^s + 1$. One can easily verify that (3) does not hold in this case. This shows that the code $C$ is not MDS when $2p^s + 1 \leq v \leq 3p^s - 1$. □

In the following theorem, we determine RT weight distributions of all $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathcal{R}$ when $\beta$ is non-zero.

Theorem 25: Let $\beta \in \mathbb{F}_{p^s} \setminus \{0\}$, and let $C = \langle (x^n - \alpha_0)^v \rangle$ be an $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathcal{R}$, where $0 \leq v \leq 3p^s$. For $0 \leq \rho \leq np^s$, let $A_\rho$ denote the number of codewords in $C$ having the RT weight as $\rho$.

(a) For $v = 3p^s$, we have

$$A_\rho = \begin{cases} 1 & \text{if } \rho = 0; \\
0 & \text{otherwise.} \end{cases}$$
(b) For $2p^s + 1 \leq v \leq 3p^s - 1$, we have

$$A_\rho = \begin{cases} 1 & \text{if } \rho = 0; \\ (p^m(3-\gamma)-1)p^{m(3-\gamma)(\rho-1)} & \text{if } 1 \leq \rho \leq np^s; \\ p^m(\rho-nv+2np^s-1) & \text{if } nv-2np^s+1 \leq \rho \leq np^s. \end{cases}$$

(c) For $v = yp^s$ with $y \in \{0, 1, 2\}$, we have

$$A_\rho = \begin{cases} 1 & \text{if } \rho = 0; \\ (p^m(3-\gamma)-1)p^{m(3-\gamma)(\rho-1)} & \text{if } 1 \leq \rho \leq np^s. \end{cases}$$

(d) For $(k-1)p^s + 1 \leq v \leq kp^s - 1$ with $k \in \{1, 2\}$, we have

$$A_\rho = \begin{cases} 1 & \text{if } \rho = 0; \\ (p^m(k-1)-1)p^{m(k-1)(\rho-1)} & \text{if } 1 \leq \rho \leq \nu(v-knp^s); \\ p^m(k-1)p^{m(\nu(v-knp^s)-2np^s)}(p^{m-k}\rho-1)p^{m(\rho-k)p} & \text{if } nv-(k-1)p^s+1 \leq \rho \leq np^s. \end{cases}$$

Proof: It is easy to see that $A_0 = 1$. So from now onwards, throughout the proof, we assume that $1 \leq \rho \leq np^s$.

(a) When $v = 3p^s$, we have $C = \{0\}$. This gives $A_\rho = 0$ for $1 \leq \rho \leq np^s$.

(b) Let $2p^s + 1 \leq v \leq 3p^s - 1$. Here by Theorem 23, we see that $d_{RT}(C) = nv - 2np^s + 1$, which gives $A_\rho = 0$ for $1 \leq \rho \leq nv - 2np^s$. Next let $nv - 2np^s + 1 \leq \rho \leq np^s$. Here by Lemma 10(b), we see that $(x^n - \alpha \lambda_0^{yp^s}) = \langle u \rangle$. This implies that $C = \langle u^2(x^n - \alpha \lambda_0^{yp^s}) - 2p^s \rangle = \langle u^2(x^n - \alpha \lambda_0^{yp^s}) - 2p^s \rangle$. If $F(x) \in \mathbb{F}_{p^m}[x]$, then we see that the RT weight of the codeword $u^2(x^n - \alpha \lambda_0^{yp^s}) - 2p^s F(x)$ is $C$ if and only if $\deg F(x) = \rho - nv + 2np^s - 1$. This gives $A_\rho = (p^m(3-\gamma)-1)p^{m(3-\gamma)(\rho-1)}$.

(c) Next let $v = yp^s$, where $y \in \{0, 1, 2\}$. Here by Lemma 10(b), we see that $C = \langle (x^n - \alpha \lambda_0^{yp^s}) \rangle = \langle u^2 \rangle$. This implies that $A_\rho = 0$ for $1 \leq \rho \leq np^s$. Here by Lemma 10(b), we have $(x^n - \alpha \lambda_0^{yp^s}) = \langle u \rangle$, which implies that $u^k \in C$ and $C = \langle (x^n - \alpha \lambda_0^{yp^s}) \rangle$. Furthermore, we see that any codeword $Q(x) \in C$ can be uniquely written as $Q(x) = u^k(x^n - \alpha \lambda_0^{yp^s}) - 1p^{m-k}H_\rho(x)$, where $H_\rho(x) \in \mathcal{P}_{np^s}(\mathbb{F}_{p^m})$ and $F_\rho(x) \in \mathcal{P}_{np^s}(\mathbb{F}_{p^m})$. When $1 \leq \rho \leq nv - (k-1)p^s$, we see that the RT weight of the codeword $Q(x) \in C$ is $\rho$ if and only if $F_\rho(x) = 0$ and $\deg H_\rho(x) = \rho - 1$. From this, we obtain $A_\rho = (p^m(k-1)-1)p^{m(k-1)(\rho-1)}$ for $1 \leq \rho \leq np^s$. Next let $nv - (k-1)p^s + 1 \leq \rho \leq np^s$. In this case, we see that the RT weight of the codeword $Q(x) \in C$ is $\rho$ if and only if exactly one of the following two conditions is satisfied: (i) $\deg F_\rho(x) = \rho - nv + (k-1)p^s - 1$ and $H_\rho(x) \in \mathcal{P}_{p^s}(\mathbb{F}_{p^m})$, and (ii) $F_\rho(x) \in \mathcal{P}_{np^s}, np^s - \nu(v-knp^s - 1)(\mathbb{F}_{p^m})$ and $\deg H_\rho(x) = \rho - 1$. From this, we obtain

$$A_\rho = (p^m(3-\gamma)-1)p^{m(3-\gamma)(\rho-1)} + p^m(k-1)p^{m(\nu(v-knp^s)-2np^s)}(p^{m-k}\rho-1)p^{m(\rho-k)p}.$$ 

This completes the proof of the theorem.

In the following theorem, Hamming distances of all non-trivial $(\alpha + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathbb{R}$ are determined.

Theorem 26: Let $C$ be a non-trivial $(\alpha + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathbb{R}$ with $\mathcal{R}_2(C) = \langle (x^n - \alpha \lambda_0^{yp^s}) \rangle$ for some integer $c$ satisfying $0 \leq c < p^s$ (as determined in Theorems 16 and 18). Then with respect to the Hamming metric, the code $C$ is an $[np^s, n(p-s^c), d_H(C)]$-code over $\mathbb{R}$, where

$$d_H(C) = \begin{cases} 1 & \text{if } c = 0; \\ \ell + 1 & \text{if } \ell \leq 1 \leq c \leq \ell + 1 \end{cases}$$

Accordingly, by Theorem 20(b), we see that $\text{rank}(C) = np^s - nc$. Furthermore, by applying Theorems 4 and 6, one can determine the Hamming distance of the code $C$.

One can easily observe that the $(\alpha + \gamma u^2)$-constacyclic code $C = \langle 1 \rangle$ of length $np^s$ over $\mathbb{R}$ is MDS with respect to both Hamming and RT metrics. In the following theorem, we list all non-trivial MDS $(\alpha + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathbb{R}$ with respect to the Hamming metric.

Theorem 27: With respect to the Hamming metric, we have the following:

(a) When $\gamma \neq 0$, there exists a non-trivial MDS $(\alpha + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathbb{R}$ if and only if $p = 2$ and $n = s = 1$. Furthermore, when $p = 2$ and $n = s = 1$, all the distinct non-trivial MDS $(\alpha + \gamma u^2)$-constacyclic codes of length 2 over $\mathbb{R}$ are given by $\langle x - \alpha \lambda_0^{yp^s} - u^2D_2 \rangle$, where $D_2 \in \mathbb{F}_{2^m}$.

(b) When $\gamma = 0$, there exists a non-trivial MDS $\alpha$-constacyclic code of length $np^s$ over $\mathbb{R}$ if and only if $n = 1$. Furthermore, when $n = 1$, all the distinct non-trivial $\alpha$-constacyclic codes of length $p^s$ over $\mathbb{R}$ are given by

$$\langle (x - \alpha \lambda_0^{yp^s} - u(x - \alpha \lambda_0^{yp^s})D_1(x) + u^2(x - \alpha \lambda_0^{yp^s})D_2(x) \rangle,$$

where $1 \leq a \leq p - 1$ if $s = 1$ while $a \in \{1, p^s - 1\}$ if $s \geq 2$, $\max(0, 2a - p^s) \leq t_1 < a$ if $D_1(x) \neq 0$, $0 \leq t_2 < a$ if $D_2(x) \neq 0$, $D_1(x)$ is either 0 or a unit in $\mathcal{R}_a$ of the form $\sum_{k=0}^{a-1-t_1} C_k(x - \alpha \lambda_0^{p^s})$ and $D_2(x)$ is either 0 or a unit in $\mathcal{R}_a$ of the form $\sum_{k=0}^{a-t_2-1} Q_k(x - \alpha \lambda_0^{p^s})$.
\( C_k, Q_k \in \mathbb{F}_{p^m} \) for each relevant \( k \) and \( \ell \), satisfying the following:
\[
u^2(x - \alpha_0)^{p^k-a+2t}D_2(x) - u^2(x - \alpha_0)^{p^k-2a+2t}D_1(x)^2 \in \langle u^2(x - \alpha_0)^a \rangle.
\]

**Proof:** Let \( \mathcal{C} \) be a non-trivial \( (\alpha + \gamma \nu^2, \alpha - \nu^2) \)-constacyclic code of length \( np^s \) over \( \mathcal{R} \) with \( \text{Tor}_2(\mathcal{C}) = \langle (x^n - \alpha_0)^{\gamma} \rangle \), where \( 0 \leq c < p^s \) (as determined in Theorems 16 and 18). Here, by Theorem 26, we note that \( d_H(\mathcal{C}) = d_H(\text{Tor}_2(\mathcal{C})) \). By (1), we have \( p^{mn(p^s-c)} = |\text{Tor}_2(\mathcal{C})| \leq p^{mn(p^s-d_H(\text{Tor}_2(\mathcal{C})))} \). This gives
\[
nc \geq d_H(\text{Tor}_2(\mathcal{C})) - 1 = d_H(\mathcal{C}) - 1.
\]

(i) First let \( \mathcal{C} \) be of Type I. Here by Theorems 16 and 18, we have \( \mathcal{C} = \langle u^n(x^n - \alpha_0)^\gamma \rangle \). By Theorems 16 and 18 again, we see that \( |\mathcal{C}| = p^{mn(p^s-c)} \). Now by (1), the code \( \mathcal{C} \) is MDS if and only if \( p^{mn(p^s-c)} = |\mathcal{C}| = p^{mn(np^s-d_H(\mathcal{C})))} \), which holds if and only if
\[
2np^s + nc \geq 3(d_H(\mathcal{C}) - 1).
\]

(ii) Now let \( \mathcal{C} \) be of Type II. Here by Theorems 16 and 18, we have \( \mathcal{C} = \langle u^n(x^n - \alpha_0)^\gamma \rangle G(x), u^n(x^n - \alpha_0)^\gamma \rangle \), where \( 0 \leq c \leq d < p^s \), max\( \{a, b+c-p^s\} \leq t < c \) if \( G(x) \neq 0 \) and \( G(x) = 0 \) is either a unit or a unit in \( \mathcal{R}_{\alpha+\gamma \nu^2} \). Now the code \( \mathcal{C} \) is MDS if and only if \( p^{mn(2p^s-b-c)} = |\mathcal{C}| = p^{mn(np^s-d_H(\mathcal{C})))} \), which holds if and only if
\[
np^s + nb + nc \geq 3(d_H(\mathcal{C}) - 1).
\]

(iii) Next let \( \mathcal{C} \) be of Type III. Here by Theorems 16 and 18, we have \( \mathcal{C} = \langle u^n(x^n - \alpha_0)^\gamma + u^n(x^n - \alpha_0)^\gamma D_1(x) + u^n(x^n - \alpha_0)^\gamma \rangle \), where \( a > 0, 0 \leq c \leq b \leq p^s \), max\( \{0, a + b - p^s\} \leq t < c \) if \( D_1(x) \neq 0 \), \( 0 \leq t < c \) if \( D_2(x) \neq 0 \), max\( \{0, b + c - p^s\} \leq \theta < c \) if \( V(x) \neq 0 \), \( D_1(x) \) is either 0 or a unit in \( \mathcal{R}_{\alpha+\gamma \nu^2} \) or the form \( \sum_{k=0}^{c-\theta-1} \sum_{l=0}^{c-\theta-1} C_k(x^n - \alpha_0)^\gamma \), where \( C_k \in \mathcal{R}_{\alpha+\gamma \nu^2} \) and \( V(x) \) is either 0 or a unit in \( \mathcal{R}_{\alpha+\gamma \nu^2} \) of the form \( \sum_{l=0}^{c-\theta-1} W_l(x^n - \alpha_0)^\gamma \) with \( C_k \), \( Q_k \), \( W_l \in \mathcal{P}(\mathbb{F}_{p^m}) \) for each relevant \( k, \ell, l \). Furthermore, by Theorems 16 and 18 again, we see that
\[
u^2\{(x^n - \alpha_0)^{p^k-a-t_1-b+\theta} V(x) D_1(x) - (x^n - \alpha_0)^{p^k-a-t_1} D_2(x) - (x^n - \alpha_0)^{p^k-a-t_2}\} \in \langle u^n(x^n - \alpha_0)^\gamma \rangle,
\]
and that \( |\mathcal{C}| = p^{mn(3p^s-a-b-\theta)} \). Now the code \( \mathcal{C} \) is MDS if and only if \( p^{mn(3p^s-a-b-\theta)} = |\mathcal{C}| = p^{mn(np^s-d_H(\mathcal{C})}) \), which holds if and only if
\[
n + nb + nc \geq 3(d_H(\mathcal{C}) - 1).
\]

By (4) and using the fact that \( a \geq b \geq c \), we have \( na + nb + nc \geq 3(d_H(\mathcal{C}) - 1) \) and equality holds if and only if \( na = nb = nc = d_H(\mathcal{C}) - 1 = d_H(\text{Tor}_2(\mathcal{C})) - 1 \). Now when \( a = b = c \), we see that \( u^n\{(x^n - \alpha_0)^\gamma D_1(x) - (x^n - \alpha_0)^\gamma V(x) \in \langle u^n(x^n - \alpha_0)^\gamma \rangle \}, \) which implies that \( t_1 = \theta \) and \( D_1(x) = V(x) \). From this and using (7), we see that
\[
u^2\{(x^n - \alpha_0)^{p^k-a-t_1-b+\theta} V(x) D_1(x) - (x^n - \alpha_0)^{p^k-a-t_1} D_2(x) - (x^n - \alpha_0)^{p^k-a-t_2}\} \in \langle u^n(x^n - \alpha_0)^\gamma \rangle,
\]
This holds if and only if \( t_1 = 0, p = 2, a = 2^\omega - 1 \) and \( D_1(x) \neq 0 \) in the case when \( \gamma \neq 0 \).

Using this, the desired result follows immediately.

\[\square\]

In the following theorem, we determine RT distances of all non-trivial \((\alpha + \gamma \nu^2)-\text{constacyclic codes of length } np^s \) over \( \mathcal{R} \).

**Theorem 28:** Let \( \mathcal{C} \) be a non-trivial \((\alpha + \gamma \nu^2)-\text{constacyclic code of length } np^s \) over \( \mathcal{R} \) with \( \text{Tor}_2(\mathcal{C}) = \langle (x^n - \alpha_0)^\gamma \rangle \) for some integer \( c \) satisfying \( 0 \leq c < p^s \) (as determined in Theorems 16 and 18). Then the code \( \mathcal{C} \) is an \([np^s, n(p^s-c), nc+1]\)-code with respect to the RT metric.

**Proof:** To prove the result, we first observe that
\[w_{RT}(Q(x)) \geq w_{RT}(uQ(x)) \text{ for each } Q(x) \in \mathcal{R}_{\alpha+\gamma \nu^2}.
\]

(i) When \( \mathcal{C} \) is of Type I, we have \( \mathcal{C} = \langle u^n(x^n - \alpha_0)^\gamma \rangle \). Here we note that \( \mathcal{C} = \langle u^n(x^n - \alpha_0)^\gamma \rangle = \langle u^n(x^n - \alpha_0)^\gamma f(x) \rangle : f(x) \in \mathbb{F}_{p^m}[x] \rangle. \) Now for each non-zero \( Q(x) \in \mathcal{C} \), by (9), we see that \( w_{RT}(Q(x)) \geq w_{RT}(u^n(x^n - \alpha_0)^\gamma f(x)) = nc + 1 \), which implies that \( d_{RT}(\mathcal{C}) \geq nc + 1 \). Since \( u^n(x^n - \alpha_0)^\gamma f(x) \in \mathcal{C} \), we obtain \( d_{RT}(\mathcal{C}) = nc + 1 \).

(ii) When \( \mathcal{C} \) is of Type II, we have \( \mathcal{C} = \langle u^n(x^n - \alpha_0)^\gamma + u^n(x^n - \alpha_0)^\gamma D_1(x) + u^n(x^n - \alpha_0)^\gamma \rangle \), where \( c \leq b < p^s \), max\( \{0, a + b - p^s\} \leq t < c \) if \( G(x) \neq 0 \) and \( G(x) \) is either 0 or a unit in \( \mathbb{F}_{p^m}[x]/\langle f(x) \rangle \). Here by (9),
we note that \( w_{\text{RT}}(Q(x)) \geq w_{\text{RT}}(uQ(x)) \) for each \( Q(x) \in C \setminus \{u^2\} \), which implies that \( w_{\text{RT}}(Q(x)) \geq d_{\text{RT}}(u(x^2 - \alpha_0)^0) \) for each \( Q(x) \in C \setminus \{u^2\} \). From this, we get \( d_{\text{RT}}(C) \geq d_{\text{RT}}(u(x^2 - \alpha_0)^0) \).

(iii) When \( C \) is of Type III, we have \( C = \langle (x^a - \alpha_0)^b \rangle \) and \( D_2(x) = \langle u(x^2 - \alpha_0)^0 \rangle \). Since \( (x^a - \alpha_0)^b \subseteq C \), we have \( d_{\text{RT}}((x^a - \alpha_0)^b) \geq d_{\text{RT}}(C) \). This implies that \( d_{\text{RT}}(C) = d_{\text{RT}}((x^a - \alpha_0)^b) \). From this and by case (i), we get \( d_{\text{RT}}(C) = nc + 1 \).

From this and by Theorem 20(b), the desired result follows. □

In the following theorem, we determine all non-trivial MDS \((\alpha + \gamma u)^2\)-constacyclic codes of length \( np^s \) over \( \mathbb{R} \) with respect to the RT metric.

**Theorem 29:** With respect to the RT metric, we have the following:

(a) When \( \gamma \neq 0 \), there exists a non-trivial MDS \((\alpha + \gamma u^2)^2\)-constacyclic code of length \( np^s \) over \( \mathbb{R} \) if and only if \( p \equiv 2 \). Furthermore, when \( p = 2 \), all the distinct \((\alpha + \gamma u^2)^2\)-constacyclic codes of length \( 2n \) over \( \mathbb{R} \) are given by

\[
\langle (x^a - \alpha_0)^{2i-1} + uD_1(x) + u^2(x^a - \alpha_0)^2D_2(x) \rangle,
\]

where \( 0 \leq t_2 < 2^{-i-1} \) if \( D_2(x) \neq 0 \), \( D_1(x) \) is a unit in \( \mathbb{R}_{\alpha + \gamma u^2} \) of the form \( \sum_{i=0}^{2i-1} B_i(x)(x^a - \alpha_0)^i \) and \( D_2(x) \) is either 0 or a unit in \( \mathbb{R}_{\alpha + \gamma u^2} \) of the form \( \sum_{i=0}^{2i-1} C_i(x)(x^a - \alpha_0)^i \) with \( B_i(x), C_i(x) \in \mathbb{P}_n(\mathbb{F}_{2^m}) \) for each relevant \( k \) and \( \ell \), satisfying the following:

\[
u^2(\gamma - D_1(x)^2) \in \langle u^2(x^a - \alpha_0)^{2i-1} \rangle.
\]

(b) When \( \gamma = 0 \), all the distinct non-trivial MDS \( \alpha \)-constacyclic codes of length \( np^s \) over \( \mathbb{R} \) are given by

\[
\langle (x^a - \alpha_0)^b + u(x^a - \alpha_0)^bD_1(x) + u^2(x^a - \alpha_0)^2D_2(x) \rangle,
\]

where \( 1 \leq \alpha \leq p^s - 1 \), \( \max(0, 2a - p^s) \leq t_1 < a \) if \( D_1(x) \neq 0 \), \( 0 \leq t_2 < a \) if \( D_2(x) \neq 0 \), \( D_1(x) \) is either 0 or a unit in \( \mathbb{R}_{\alpha + \gamma u^2} \) of the form \( \sum_{i=0}^{t_2-1} Q_i(x)(x^a - \alpha_0)^i \) and \( V(x) \) is either 0 or a unit in \( \mathbb{R}_{\alpha + \gamma u^2} \) of the form \( \sum_{i=0}^{t_2-1} W_i(x)(x^a - \alpha_0)^i \) with \( C_i(x), Q_i(x), W_i(x) \in \mathbb{P}_n(\mathbb{F}_{2^m}) \) for each relevant
that $|C| = p^{\text{nn}(3p^r-a-b-c)}$. Now the code $C$ is MDS with respect to the RT metric if and only if $p^{\text{nn}(3p^r-a-b-c)} = |C| = p^{3n(np^d-\deg(C)+1)},$ which holds if and only if

$$na + nb + nc = 3(d_{RT}(C) - 1) = 3nc. \tag{13}$$

Using the fact that $a \geq b \geq c$, we obtain $na + nb + nc \geq 3nc$, and the equality holds if and only if $a = b = c$. Now when $a = b = c$, we see that $u^2[(x^n - \alpha_0)^{3p^r}D_1(x) - (x^n - \alpha_0)^{3p^r}V(x)] \in \langle u^2(x^n - \alpha_0)^c \rangle$, which implies that $t_1 = \theta$ and $D_1(x) = V(x)$. From this and using (12), we get $u^2[(x^n - \alpha_0)^{3p^r-a}D_1(x)^2 - (x^n - \alpha_0)^{3p^r-a}V(x)] \in \langle u^2(x^n - \alpha_0)^c \rangle$. This holds if and only if $t_1 = 0$, $p = 2$, $a = 2^{e-1}$ and $D_1(x) \neq 0$ in the case when $\gamma \neq 0$.

From this, the desired result follows.

In the following theorem, we determine RT weight distributions of all $(a + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathcal{R}$.

**Theorem 30:** Let $C$ be an $(a + \gamma u^2)$-constacyclic code of length $np^s$ over $\mathcal{R}$ with $\text{Tor}_0(C) = (x^n - \alpha_0)^b$, $\text{Tor}_1(C) = (x^n - \alpha_0)^b$ and $\text{Tor}_2(C) = (x^n - \alpha_0)^c$ for some integers $a, b, c$ satisfying $0 \leq c \leq b \leq a \leq p^s$ (as determined in Theorems 16 and 18). For $0 \leq \rho \leq np^s$, let $A_\rho$ denote the number of codewords in $C$ having the RT weight as $\rho$.

(a) If $C = \{0\}$, then we have $A_0 = 1$ and $A_\rho = 0$ for $1 \leq \rho \leq np^s$.

(b) If $C = \{1\}$, then we have $A_0 = 1$ and $A_\rho = (p^3m - 1)p^{3m(\rho-1)}$ for $1 \leq \rho \leq np^s$.

(c) If $C = \langle u^2(x^n - \alpha_0)^c \rangle$ is of Type I, then we have

$$A_\rho = \begin{cases} 1 & \text{if } \rho = 0; \\ 0 & \text{if } 1 \leq \rho \leq nc; \\ (p^m - 1)p^{m(\rho-nc-1)} & \text{if } nc + 1 \leq \rho \leq np^s. \end{cases}$$

(d) If $C = \langle u(x^n - \alpha_0)^b + u^2(x^n - \alpha_0)^c \rangle$ is of Type II, then we have

$$A_\rho = \begin{cases} 1 & \text{if } \rho = 0; \\ 0 & \text{if } 1 \leq \rho \leq nc; \\ (p^m - 1)p^{m(\rho-nc-1)} & \text{if } nc + 1 \leq \rho \leq nb; \\ (p^m - 1)p^{m(2\rho-nb-nc-2)} & \text{if } nb + 1 \leq \rho \leq np^s. \end{cases}$$

(e) If $C = \langle (x^n - \alpha_0)^a + u(x^n - \alpha_0)^bD_1(x) + u^2(x^n - \alpha_0)^cD_2(x), u(x^n - \alpha_0)^b + u^2(x^n - \alpha_0)^cV(x), u^2(x^n - \alpha_0)^c \rangle$ is of Type III, then we have

$$A_\rho = \begin{cases} 1 & \text{if } \rho = 0; \\ 0 & \text{if } 1 \leq \rho \leq nc; \\ (p^m - 1)p^{m(\rho-nc-1)} & \text{if } nc + 1 \leq \rho \leq nb; \\ (p^m - 1)p^{m(2\rho-nb-nc-2)} & \text{if } nb + 1 \leq \rho \leq na; \\ (p^m - 1)p^{m(3\rho-na-nb-nc-3)} & \text{if } na + 1 \leq \rho \leq np^s. \end{cases}$$

Proof: Proofs of parts (a) and (b) are trivial. To prove parts (c)-(e), by Theorem 28(c), we see that $d_{RT}(C) = nc + 1$, which implies that $A_0 = 0$ for $1 \leq \rho \leq nc$. So from now on, we assume that $nc + 1 \leq \rho \leq np^s$.

(c) Let $C = \langle u^2(x^n - \alpha_0)^c \rangle$. Here we see that $C = \langle u^2(x^n - \alpha_0)^c \rangle = \langle u^2(x^n - \alpha_0)^cF(x) : F(x) \in \mathbb{F}_{p^m}[x] \rangle$. This implies that the codeword $u^2(x^n - \alpha_0)^cF(x) \in C$ has RT weight $\rho$ if and only if $\deg F(x) = \rho - nc - 1$. From this, we obtain $A_\rho = (p^m - 1)p^{m(\rho-nc-1)}$.

(d) Let $C = \langle u(x^n - \alpha_0)^b + u^2(x^n - \alpha_0)^c \rangle$. Here we observe that each codeword $Q(x) \in C$ can be uniquely expressed as $Q(x) = (u(x^n - \alpha_0)^b + u^2(x^n - \alpha_0)^c)A_0(x) + u^2(x^n - \alpha_0)^cB_0(x)$, where $A_0(x), B_0(x) \in \mathbb{F}_{p^m}[x]$ satisfy $\deg A_0(x) \leq n(p^s - b - 1)$ if $A_0(x) \neq 0$ and $\deg B_0(x) \leq n(p^s - c - 1)$ if $B_0(x) \neq 0$. From this, we see that if $nc + 1 \leq \rho \leq nb$, then the RT weight of the codeword $Q(x) \in C$ is $\rho$ if and only if $A_0(x) = 0$ or $B_0(x) = 0$. This implies that $A_\rho = (p^m - 1)p^{m(\rho-nc-1)}$ for $nc + 1 \leq \rho \leq nb$. Further, if $nb + 1 \leq \rho \leq np^s$, then the RT weight of the codeword $Q(x) \in C$ is $\rho$ if and only if one of the following two conditions are satisfied:

(i) $\deg A_0(x) = \rho - nb - 1$ and $B_0(x)$ is either 0 or $\deg B_0(x) \leq \rho - nc - 1$ and (ii) $A_0(x)$ is either 0 or $\deg A_0(x) \leq \text{textrho} - nb - 2$ and $\deg B_0(x) = \rho - nc - 1$. From this, we get $A_\rho = (p^m - 1)p^{m(\rho-nc-2)}$ for $nb + 1 \leq \rho \leq np^s$.

(e) Let $C = \langle (x^n - \alpha_0)^a + u(x^n - \alpha_0)^bD_1(x) + u^2(x^n - \alpha_0)^cD_2(x), u(x^n - \alpha_0)^b + u^2(x^n - \alpha_0)^cV(x), u^2(x^n - \alpha_0)^c \rangle$. Here we see that each codeword $Q(x) \in C$ can be uniquely expressed as $Q(x) = ((x^n - \alpha_0)^a + u(x^n - \alpha_0)^bD_1(x) + u^2(x^n - \alpha_0)^cD_2(x))M_0(x) + (ux^n - \alpha_0)^b + u^2(x^n - \alpha_0)^cV(x)N_0(x) + u^2(x^n - \alpha_0)^cW_0(x)$, where $M_0(x), N_0(x), W_0(x) \in \mathbb{F}_{p^m}[x]$ satisfy $\deg M_0(x) \leq n(p^s - a - 1)$ if $M_0(x) \neq 0$, $\deg N_0(x) \leq n(p^s - b - 1)$ if $N_0(x) \neq 0$, and $\deg W_0(x) \leq n(p^s - c - 1)$ if $W_0(x) \neq 0$. If $nc + 1 \leq \rho \leq nb$, then the codeword $Q(x) \in C$ has RT weight $\rho$ if and only if $M_0(x) = N_0(x) = 0$ and $\deg W_0(x) = \rho - nc - 1$. This implies that $A_\rho = (p^m - 1)p^{m(\rho-nc-1)}$.
(i) deg $N_Q(x) = \rho - nb - 1$ and $W_Q(x)$ is either 0 or deg $W_Q(x) \leq \rho - 1 - nc$; and (ii) $N_Q(x)$ is either 0 or deg $N_Q(x) \leq \rho - nb - 2$ and deg $W_Q(x) = \rho - nc - 1$. This implies that $A_\rho = (p^{2m} - 1)p^{m(2p^{\rho m - n_1} - 2)}$.

Next let $na + 1 \leq \rho \leq np^4$. Here the RT weight of the codeword $Q(x) \in C$ is $\rho$ if and only if exactly one of the following three conditions is satisfied: (i) deg $M_Q(x) = \rho - na - 1$, $N_Q(x)$ is either 0 or deg $N_Q(x) \leq \rho - nb - 1$ and $W_Q(x)$ is either 0 or deg $W_Q(x) \leq \rho - nc - 1$; (ii) $M_Q(x)$ is either 0 or deg $M_Q(x) \leq \rho - na - 2$, deg $N_Q(x) = \rho - nb - 1$ and $W_Q(x)$ is either 0 or deg $W_Q(x) \leq \rho - nc - 1$; and (iii) $M_Q(x)$ is either 0 or deg $M_Q(x) \leq \rho - na - 2$, deg $N_Q(x) \leq \rho - nb - 2$ and deg $W_Q(x) = \rho - nc - 1$. This implies that $A_\rho = (p^{3m} - 1)p^{m(3p^{\rho m - na - nb - nc} - 3)}$ for $na + 1 \leq \rho \leq np^4$.

This completes the proof of the theorem. □

V. HAMMING DISTANCES OF CONSTACYCLIC CODES OF LENGTH $2p^s$ OVER $R$ AND DETERMINATION OF MDS CODES

Throughout this section, let $p$ be an odd prime. Here we will determine Hamming distances of all constacyclic codes of length $2p^s$ over $R$, and we will also identify all MDS constacyclic codes of length $2p^s$ over $R$ with respect to the Hamming metric. For this, we recall that $\lambda = \alpha + \beta u + \gamma u^2$, where $\alpha, \beta, \gamma$ are elements of $\mathbb{F}_{p^m}$ and $\alpha$ is non-zero. By Lemma 3(b), we see that there exists $a_0(\neq 0) \in \mathbb{F}_{p^m}$ such that $\alpha = a_0^2$. Here we have $R_{\lambda} = R[x]/(x^{2p^s} - \lambda)$.

When $a_0 \in \mathbb{F}_{p^m}$ is not a square in $\mathbb{F}_{p^m}$, the binomial $x^2 - a_0$ is irreducible over $\mathbb{F}_{p^m}$, and one can determine Hamming distances of all $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $2p^s$ over $R$ and identify all MDS codes within this class of codes on taking $n = 2$ in Theorems 21, 22, 26 and 27.

So from now on, throughout this section, we assume that $a_0(\neq 0) \in \mathbb{F}_{p^m}$ is a square in $\mathbb{F}_{p^m}$, i.e., there exists $\xi(\neq 0) \in \mathbb{F}_{p^m}$ such that $\alpha = \xi^2$. This implies that $x^2 - a_0 = (x - \xi)(x - \xi)$. From this and working as in Section III, we get

$$R_{\lambda} \simeq K_1 \oplus K_2,$$

where $K_1 = R[x]/(x + \xi)^d + u(g_1(x) + u^2 h_1(x))$ and $K_2 = R[x]/(x - \xi)^d + u(g_2(x) + u^2 h_2(x))$, where for $j \in \{1, 2\}$, the polynomials $g_j(x), h_j(\in \mathbb{F}_{p^m}[x]$ satisfy $gcd(x + \xi, g_j(x)) = gcd(x - \xi, g_j(x)) = 1$ when $\beta \neq 0$, $g_j(x) = h_j(x) = 0$ when $\beta = \gamma = 0$, and $g_j(x)$ is 0 and $gcd(x + \xi, h_j(x)) = gcd(x - \xi, h_j(x)) = 1$ when $\beta = 0$ and $\gamma \neq 0$.

Now let $C$ be an $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $2p^s$ over $R$, i.e., an ideal of the ring $R_{\lambda}$. Then by Proposition 8, we have

$$C = C_1 \oplus C_2,$$

where $C_j$ is an ideal of $K_j$ for $j \in \{1, 2\}$. Further, we note that an element $a(x) \in R_{\lambda}$ can be written as $a(x) = a_0(x) + u a_1(x) + u^2 a_2(x)$, where $a_0(x), a_1(x), a_2(x) \in \mathbb{F}_{p^m}[x]/(x^2 - a_0^\rho)$.

Let us define $Tor_0(C) = \{c_0(x) \in \mathbb{F}_{p^m}[x]/(x^2 - a_0^\rho) : c_0(x) + c_1(x) + u^2 c_2(x) \in C$ for some $c_1(x), c_2(x) \in \mathbb{F}_{p^m}[x]/(x^2 - a_0^\rho)\}$, $Tor_1(C) = \{c_1(x) \in \mathbb{F}_{p^m}[x]/(x^2 - a_0^\rho) : u c_1(x) + u^2 c_2(x) \in C$ for some $c_1(x), c_2(x) \in \mathbb{F}_{p^m}[x]/(x^2 - a_0^\rho)\}$ and $Tor_2(C) = \{c_2(x) \in \mathbb{F}_{p^m}[x]/(x^2 - a_0^\rho) : u^2 c_2(x) \in C\}$. Then we make the following observation.

**Proposition 31:** Let $C = C_1 \oplus C_2$ be an $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $2p^s$ over $R$ (i.e., an ideal of the ring $R_{\lambda}$), where $C_j$ is an ideal of $K_j$ for $j \in \{1, 2\}$. Then $Tor_0(C), Tor_1(C)$ and $Tor_2(C)$ are ideals of $\mathbb{F}_{p^m}[x]/(x^2 - a_0^\rho)$. Moreover, we have $Tor_0(C) = Tor_1(C) \oplus Tor_2(C)$ for $0 \leq i \leq 2$, where for $i \in \{0, 1, 2\}$, $Tor_1(C)$ and $Tor_2(C)$ are ideals of $\mathbb{F}_{p^m}[x]/(x + \xi)^i$ and $\mathbb{F}_{p^m}[x]/(x - \xi)^i$, respectively. Further, as $\mathbb{F}_{p^m}[x]/(x + \xi)^i$ and $\mathbb{F}_{p^m}[x]/(x - \xi)^i$ are finite commutative chain rings with the respective maximal ideals as $(x + \xi)$ and $(x - \xi)$, we have $Tor_0(C_1) = \{(x + \xi)^a \}$, $Tor_0(C_2) = \{(x - \xi)^a \}$, $Tor_1(C_1) = \{(x + \xi)^a \}$, $Tor_1(C_2) = \{(x - \xi)^a \}$, $Tor_2(C_1) = \{(x + \xi)^a \}$ and $Tor_2(C_2) = \{(x - \xi)^a \}$ for some integers $a_1, b_1, a_2, b_2, c_1, c_2$ satisfying $0 \leq a \leq b_1 \leq a_1 \leq p^s$ and $0 \leq c_2 \leq b_2 \leq a_2 \leq p^s$. Now by applying the Chinese Remainder Theorem, we get $Tor_0(C) = \{(x + \xi)^a \} (x - \xi)^b$ and $Tor_1(C) = \{(x + \xi)^a \} (x - \xi)^b$ and $Tor_2(C) = \{(x + \xi)^a \} (x - \xi)^b$.

In the following theorem, Hamming distances of all non-zero $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $2p^s$ over $R$ are determined.

**Theorem 33:** Let $C$ be a non-zero $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $2p^s$ over $R$ with $Tor_2(C) = \{(x + \xi)^a \} (x - \xi)^b$ for some integers $c_1, c_2$ satisfying $0 \leq c_1, c_2 \leq p^s$.

(a) When $c_1 \geq c_2$, the Hamming distance $d_H(C)$ of the code $C$ is given by

$$d_H(C) = \begin{cases} 1 & \text{if } c_1 = c_2 = 0; \\ 2 & \text{if } c_2 = 0 \text{ and } 0 < c_1 \leq p^s; \\ \min(\ell + 2p^s, 2(\ell + 2p^s)) & \text{if } p^{s-\ell} - p^{s-k} + p^{\ell - k - 1} + 1 \leq c_1 \leq p^{s-k} + (\ell + 1)p^{s-k} - k \text{ and } p^{s-k} + k \leq c_2 \leq p^{s-k} + (\ell + 1)p^{s-k} - k \text{ with } 0 \leq \ell, k \leq p - 2, \\ 2(p^s - 1) & \text{if } c_1 = p^{s-k} \text{ and } p^{s-k} - k \leq c_2 \leq p^{s-k} - 1 \text{ and } 0 \leq k \leq s - 1; \\ 2(p^s - 1) & \text{if } c_1 = p^{s-k} \text{ and } p^{s-k} - k \leq c_2 \leq p^{s-k} - 1 \text{ and } 0 \leq k \leq s - 1. \end{cases}$$
When \( c_2 \geq c_1 \), the Hamming distance \( d_H(C) \) of the code \( C \) is given by

\[
d_H(C) = \begin{cases}
1 & \text{if } c_1 = c_2 = 0; \\
2 & \text{if } c_1 = 0 \text{ and } 0 < c_2 \leq p^s; \\
\min((\ell + 2)p^k, 2(\ell + 1)p^k) & \text{if } p^s - p^{s-k} + \ell p^{s-k-1} + 1 \leq c_2 \leq p^s - p^{s-k} + (\ell + 1)p^{s-k-1} \text{ and } p^s - p^{s-k} + \ell p^{s-k-1} + 1 \leq c_1 \leq p^s - p^{s-k} + (\ell + 1)p^{s-k-1} \text{ with } 0 \leq \ell, \ell \leq p - 2, \text{ and } 0 \leq k' \leq k \leq s - 1; \\
2(\ell + 1)p^k & \text{if } c_2 = p^s \text{ and } p^s - p^{s-k'} + \ell p^{s-k'-1} + 1 \leq c_1 \leq p^s - p^{s-k'} + (\ell + 1)p^{s-k'-1} \text{ with } 0 \leq \ell \leq p - 2, \text{ and } 0 \leq k' \leq s - 1.
\end{cases}
\]

Proof: It follows immediately by applying Theorems 5 and 6.

In the following theorem, we derive a necessary and sufficient conditions for an \((\alpha + \beta u + \gamma u^2)\)-constacyclic code of length \( 2p^s \) over \( \mathbb{R} \) to be an MDS code with respect to the Hamming metric.

Theorem 34: Let \( C \) be an \((\alpha + \beta u + \gamma u^2)\)-constacyclic code of length \( 2p^s \) over \( \mathbb{R} \) with \( \text{Tor}_0(C) = \langle (x + \xi)^j (x - \xi)^2 \rangle \), \( \text{Tor}_1(C) = \langle (x + \xi)^j (x - \xi)^2 \rangle \) and \( \text{Tor}_2(C) = \langle (x + \xi)^j (x - \xi)^2 \rangle \) for some integers \( a_1, b_1, c_1, a_2, b_2, c_2 \) satisfying \( 0 \leq c_1 \leq b_1 \leq a_1 \leq p^s \) and \( 0 \leq c_2 \leq b_2 \leq a_2 \leq p^s \). Then the code \( C \) is an MDS code with respect to the Hamming metric if and only if \( a_1 = b_1 = c_1, a_2 = b_2 = c_2 \) and \( \text{Tor}_2(C) \) is an MDS \( \alpha \)-constacyclic code of length \( 2p^s \) over \( \mathbb{F}_{p^m} \) with respect to the Hamming metric.

Proof: To prove this, see, by (14), that \( C = C_1 \oplus C_2 \), where \( C_j \) is an ideal of \( K_j \) for \( j \in \{1, 2\} \). Further, by applying Proposition 31 and the Chinese Remainder Theorem, we get \( \text{Tor}_0(C_1) = \langle (x + \xi)^j \rangle, \text{Tor}_0(C_2) = \langle (x - \xi)^2 \rangle, \text{Tor}_1(C_1) = \langle (x + \xi)^j \rangle, \text{Tor}_1(C_2) = \langle (x - \xi)^2 \rangle, \text{Tor}_2(C_1) = \langle (x + \xi)^j \rangle \) and \( \text{Tor}_2(C_2) = \langle (x - \xi)^2 \rangle \).

Now since \( C = C_1 \oplus C_2 \), by Lemma 11, we have

\[
|C| = |C_1||C_2| = |\text{Tor}_0(C_1)||\text{Tor}_1(C_1)||\text{Tor}_2(C_1)||\text{Tor}_0(C_2)||\text{Tor}_1(C_2)||\text{Tor}_2(C_2)| = p^{6m(6p^d-a_1-a_2-b_1-b_2-c_1-c_2)}.
\]

From this, we observe that the code \( C \) is MDS with respect to the Hamming metric if and only if

\[
p^{6m(6p^d-a_1-a_2-b_1-b_2-c_1-c_2)} = |C| = p^{3m(2p^d-d_H(C)+1)},
\]

which holds if and only if

\[
a_1 + a_2 + b_1 + b_2 + c_1 + c_2 + 3 = 3d_H(C).
\]

Next by Theorem 6, we see that the Hamming distance \( d_H(C) \) of the code \( C \) is equal to the Hamming distance \( d_H(\text{Tor}_2(C)) \) of the \( \alpha \)-constacyclic code \( \text{Tor}_2(C) = \langle (x + \xi)^j (x - \xi)^2 \rangle \) of length \( 2p^d \) over \( \mathbb{F}_{p^m} \). Now by the Singleton bound (1) for \( \text{Tor}_2(C) \), we have \( p^{6m(2p^d-c_1-c_2)} \leq p^{6m(2p^d-d_H(\text{Tor}_2(C))+1)}, \) which implies that \( c_1 + c_2 + 1 \geq d_H(\text{Tor}_2(C)) = d_H(C). \) From this and using the fact that \( p^s \geq a_1 \geq b_1 \geq c_1 \geq 0 \) and \( p^s \geq a_2 \geq b_2 \geq c_2 \geq 0 \), we obtain \( a_1 + a_2 + b_1 + b_2 + c_1 + c_2 + 3 \geq 3d_H(C) \), with the equality holds if and only if \( a_1 = b_1 = c_1, a_2 = b_2 = c_2 \) and \( \text{Tor}_2(C) \) is an MDS code of length \( 2p^d \) over \( \mathbb{F}_{p^m} \) with respect to the Hamming metric. This completes the proof of the theorem.

In the following theorem, we list all non-trivial MDS \((\alpha + \beta u + \gamma u^2)\)-constacyclic codes of length \( 2p^s \) over \( \mathbb{R} \) with respect to the Hamming metric.

Theorem 35: With respect to the Hamming metric, we have the following:

(a) When either \( \beta \) is non-zero or \( \gamma \) is non-zero, there does not exist any non-trivial MDS \((\alpha + \beta u + \gamma u^2)\)-constacyclic code of length \( 2p^s \) over \( \mathbb{R} \).

(b) When \( \beta = \gamma = 0 \), all the distinct non-trivial \( \alpha \)-constacyclic codes of length \( 2p^s \) over \( \mathbb{R} \) are as listed below:

\[
\langle (x + \xi)^j + a(x + \xi)^j D_1(x) + a^2(x + \xi)^j D_2(x) \rangle \oplus C_2,
\]

where either \( a_1 = p^s - 1 \) and \( C_2 = \{0\} \) or \( a_1 = 1 \) and \( C_2 = \{1\} \) with \( \max(0, 2a_2 - p^s) \leq k_1 < a_1 \), if \( D_1(x) \neq 0, 0 \leq t_2 < a_1 \) if \( D_2(x) \neq 0, D_1(x) \) is either 0 or a unit in \( K_1 \) of the form \( \sum_{k=0}^{n-1} C_k (x + \xi)^j \) and \( D_2(x) \) is either 0 or a unit in \( K_2 \) of the form \( \sum_{k=0}^{n-1} Q_k (x - \xi)^j \) with \( C_k, Q_k \in \mathbb{F}_{p^m} \) for each relevant \( k \) and \( \ell \), satisfying the following:

\[
u^2(x + \xi)^{p^s - 1} D_2(x) = u^2(x + \xi)^{p^s - 2a_1 + 2a_2} D_1(x) \xi^2 \in \langle \xi^2 (x + \xi)^{p^s} \rangle.
\]

Proof: To prove the result, let \( C \) be a non-zero \((\alpha + \beta u + \gamma u^2)\)-constacyclic code of length \( 2p^s \) over \( \mathbb{R} \) with \( \text{Tor}_0(C) = \langle (x + \xi)^j (x - \xi)^2 \rangle, \text{Tor}_1(C) = \langle (x + \xi)^j (x - \xi)^2 \rangle \) and \( \text{Tor}_2(C) = \langle (x + \xi)^j (x - \xi)^2 \rangle \) for some integers \( a_1, b_1, c_1, a_2, b_2, c_2 \) satisfying \( 0 \leq c_1 \leq b_1 \leq a_1 \leq p^s \) and \( 0 \leq c_2 \leq b_2 \leq a_2 \leq p^s \). Then by (14), we have \( C = C_1 \oplus C_2 \), where \( C_j \) is an ideal of \( K_j \) for \( j \in \{1, 2\} \). Further, by applying Proposition 31 and the Chinese Remainder Theorem, we have \( \text{Tor}_0(C_1) = \langle (x + \xi)^j \rangle, \text{Tor}_0(C_2) = \langle (x - \xi)^2 \rangle, \text{Tor}_1(C_1) = \langle (x + \xi)^j \rangle, \text{Tor}_1(C_2) = \langle (x - \xi)^2 \rangle, \text{Tor}_2(C_1) = \langle (x + \xi)^j \rangle \) and \( \text{Tor}_2(C_2) = \langle (x - \xi)^2 \rangle \).

\[
V_1(x) = \langle \xi^2 (x + \xi)^{p^s} \rangle.
\]
By Theorem 34, we see that the code $C$ is MDS with respect to the Hamming metric if and only if $a_1 = b_1 = c_1$, $a_2 = b_2 = c_2$ and $\text{Tor}_2(C)$ is an MDS $\alpha$-constacyclic code of length $2p^s$ over $\mathbb{F}_{p^m}$ with respect to the Hamming metric. Now we shall distinguish the following two cases: (i) $\beta \neq 0$ and (ii) $\beta = 0$.

(i) First let $\beta \neq 0$. Here by Lemma 10(b), we note that $(x + \zeta)^{p^s} = (u)$ in $K_1$ and $(x - \zeta)^{p^s} = (u)$ in $K_2$. This implies that when $1 \leq a_1, a_2 \leq p^s - 1$, we have $u \in C_1$ and $u \in C_2$, which implies that $b_1 = c_1 = 0$ and $b_2 = c_2 = 0$. In view of this and by applying Theorems 34 and 5, we observe that the code $C$ is MDS if and only if $a_1 = b_1 = c_1 = 0$ and $a_2 = b_2 = c_2 = 0$. So the code $C = (1)$ is the only MDS $(\alpha + \beta u + \gamma u^2)$-constacyclic code of length $2p^s$ over $R$ with respect to the Hamming metric.

(ii) Next let $\beta = 0$. Here we see that $$(x + \zeta)^{p^s} - (x - \zeta)^{p^s} = 1,$$ which gives $$x^{2p^s} - \alpha - \gamma u^2 = \left((x + \zeta)^{p^s} + u^2\gamma(2\zeta^{p^s})^{-1}\right) \times \left((x - \zeta)^{p^s} - u^2\gamma(2\zeta^{p^s})^{-1}\right).$$

From this, we have $g_1(x) = g_2(x) = 0$, $h_1(x) = \gamma(2\zeta^{p^s})^{-1}$ and $h_2(x) = -\gamma(2\zeta^{p^s})^{-1}$. Now we proceed to determine all MDS codes in this case.

To do this, by Theorems 34 and 5, we observe that the code $C$ is an MDS code if and only if exactly one of the following conditions is satisfied:

- $a_1 = b_1 = c_1 = p^s - 1$ and $a_2 = b_2 = c_2 = p^s$.
- $a_1 = b_1 = c_1 = p^s$ and $a_2 = b_2 = c_2 = p^s - 1$.
- $a_1 = c_1 = 0$ and $a_2 = b_2 = c_2 = 0$.
- $a_1 = b_1 = c_1 = 0$ and $a_2 = b_2 = c_2 = 1$; and
- $a_1 = b_1 = c_2 = b_2 = c_2 = 0$.

Let us first consider the case $a_1 = b_1 = c_1 = p^s - 1$ and $a_2 = b_2 = c_2 = p^s$. In this case, we must have $C_2 = [0]$. As $a_1 = b_1 = c_1$, by Theorems 16 and 18, we observe that the code $C_1$ must be of Type III. So we have $C = \langle (x + \zeta)^{p^s} + u(x + \zeta)^{m}D_1(x) + u^2(x + \zeta)^{m}D_2(x), u(x + \zeta)^{m} + u^2(x + \zeta)^{m}V(x), u^2(x + \zeta)^{m}\rangle$, where $\min \{0, 2a_1 - p^s\} \leq t_1 < 1$ if $D_1(x) \neq 0$, $0 \leq t_2 < a_1$ if $D_2(x) \neq 0$, $\min \{0, 2a_1 - p^s\} \leq \theta < a_1$ if $V(x) \neq 0$. $D_1(x)$ is either 0 or a unit in $K_1$ of the form $\sum_{k=0}^{a_1-t_1-1} C_k(x + \zeta)^k$, $D_2(x)$ is either 0 or a unit in $K_1$ of the form $\sum_{k=0}^{a_1-t_1-1} Q_l(x + \zeta)^k$ and $V(x)$ is either 0 or a unit in $K_1$ of the form $\sum_{k=0}^{a_1-t_1-1} W_j(x + \zeta)^k$ with $C_k, Q_l, W_j \in \mathbb{F}_{p^m}$ for each relevant $k, l$ and $i$.

Furthermore, by Theorems 16 and 18, again we see that $$u^2\gamma(2\zeta^{p^s})^{-1} + (x + \zeta)^{-2a_1+\theta}V(x)D_1(x) - (x + \zeta)^{-a_1+2}D_2(x) \in \langle u^2(x + \zeta)^{a_1}\rangle.$$ We also note that $u^2\gamma(2\zeta^{p^s})^{-1} + (x + \zeta)^{-2a_1+\theta}V(x)D_1(x) - (x + \zeta)^{-a_1+2}D_2(x) \in \langle u^2(x + \zeta)^{a_1}\rangle$, which implies that $t_1 = \theta$ and $D_1(x) = V(x)$. From this and by (15), we get $$u^2\gamma(2\zeta^{p^s})^{-1} + (x + \zeta)^{-2a_1+\theta}V(x)D_1(x) - (x + \zeta)^{-a_1+2}D_2(x) \in \langle u^2(x + \zeta)^{a_1}\rangle.$$ This holds if and only if $t_1 = 0, p = 2, a = 2s-1$ and $D_1(x) \neq 0$ in the case when $\gamma \neq 0$. Hence we get a contradiction in this case when $\gamma$ is non-zero.

VI. CONCLUSION AND FUTURE WORK

Let $p$ be a prime, $n, s, m$ be positive integers with $\gcd(n, p) = 1$, $\mathbb{F}_{p^m}$ be the finite field of order $p^m$, and let $\mathbb{R} = \mathbb{F}_{p^m}[u]/(u^2)$ be the finite commutative chain ring with unity. Let $\alpha, \beta, \gamma \in \mathbb{F}_{p^m}$ and $\alpha \neq 0$. When $\alpha$ is an nth power of an element in $\mathbb{F}_{p^m}$ and $\beta = 0$, one can determine all $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathbb{R}$ by applying the results derived in Cao [7] and by establishing a ring isomorphism from $\mathbb{R}[x]/(x^{np^s} - 1 - \alpha^{-1}\beta u - \alpha^{-1}u^2)$ onto $\mathbb{R}[x]/(x^{np^s} - \alpha - \beta u - u^2)$. However, when $\alpha$ is not an nth power of an element in $\mathbb{F}_{p^m}$, algebraic structures of all $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathbb{R}$ and their dual codes were not established. In this paper, we determined all $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathbb{R}$ and their dual codes. We also listed some isodual $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathbb{R}$ when the binomial $x^s - \alpha_0$ is irreducible over $\mathbb{F}_{p^m}$. We also obtained Hamming distances, RT distances and RT weight distributions of all $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathbb{R}$ and determined all MDS $(\alpha + \beta u + \gamma u^2)$-constacyclic codes of length $np^s$ over $\mathbb{R}$ with respect to the Hamming and RT metrics when the binomial $x^s - \alpha_0$ is irreducible over $\mathbb{F}_{p^m}$. Besides this, we obtained Hamming distances of all constacyclic codes of length $2p^s$ over $\mathbb{R}$ and identified all MDS codes within this class of constacyclic codes with respect to the Hamming metric.

It would be interesting to determine their Hamming distances, RT distances and RT weight distributions in the case when $n \geq 3$ and the binomial $x^s - \alpha_0$ is irreducible over $\mathbb{F}_{p^m}$. Another interesting problem would be to study their duality properties and to determine their homogeneous distances.

S. Zhu, X. Kai, and P. Li, “Negacyclic MDS codes over $GR(2^m)$,” in *Proc. IEEE Int. Symp. Inform. Theory*, Jul. 2009, pp. 1730–1733.

**TANIA SIDANA** received the M.Sc. degree in mathematics from the Centre for Advanced Study in Mathematics, Panjab University, Chandigarh, India, in 2015. She is currently pursuing the Ph.D. degree with the Department of Mathematics, Indraprastha Institute of Information Technology, Delhi (IIIT-Delhi), New Delhi, India. Her research interests include coding theory, number theory, and group algebras.

**ANURADHA SHARMA** received the B.Sc. degree (Hons.) in mathematics and the M.Sc. and Ph.D. degrees in mathematics from the Centre for Advanced Study in Mathematics, Panjab University, Chandigarh, India, in 2000, 2002, and 2006, respectively. She is currently an Associate Professor with the Department of Mathematics, Indraprastha Institute of Information Technology, Delhi (IIIT-Delhi), New Delhi, India. Prior to joining IIIT-Delhi, she has worked as an Assistant Professor with the Department of Mathematics, IIT Delhi, for around five and a half years and an Assistant Professor with the Centre for Advanced Study in Mathematics, Panjab University, for around three years. She is also working in algebraic coding theory. Her other research interests include number theory and algebra. At IIT Delhi, she received the Kusuma Outstanding Young Faculty Fellowship. She was awarded the University Gold Medal for standing first in M.Sc.
