We propose heavy ball neural ordinary differential equations (HBNODEs), leveraging the continuous limit of the classical momentum accelerated gradient descent, to improve neural ODEs (NODEs) training and inference. HBNODEs have two properties that imply practical advantages over NODEs: (i) The adjoint state of an HBNODE also satisfies an HBNODE, accelerating both forward and backward ODE solvers, thus significantly reducing the number of function evaluations (NFEs) and improving the utility of the trained models. (ii) The spectrum of HBNODEs is well structured, enabling effective learning of long-term dependencies from complex sequential data. We verify the advantages of HBNODEs over NODEs on benchmark tasks, including image classification, learning complex dynamics, and sequential modeling. Our method requires remarkably fewer forward and backward NFEs, is more accurate, and learns long-term dependencies more effectively than the other ODE-based neural network models. Code is available at https://github.com/hedixia/HeavyBallNODE.

1 Introduction

Neural ordinary differential equations (NODEs) are a family of continuous-depth machine learning (ML) models whose forward and backward propagations rely on solving an ODE and its adjoint equation [Chen et al., 2018]. NODEs model the dynamics of hidden features $h(t) \in \mathbb{R}^N$ using an ODE, which is parametrized by a neural network $f(h(t), t, \theta) \in \mathbb{R}^N$ with learnable parameters $\theta$, i.e.,

$$\frac{dh(t)}{dt} = f(h(t), t, \theta).$$

---

*Co-first author
†Please correspond to: wangbaonj@gmail.com
Starting from the input \( h(t_0) \), NODEs obtain the output \( h(T) \) by solving (1) for \( t_0 \leq t \leq T \) with the initial value \( h(t_0) \), using a black-box numerical ODE solver. The number of function evaluations (NFEs) that the black-box ODE solver requires in a single forward pass is an analogue for the continuous-depth models [Chen et al., 2018] to the depth of networks in ResNets. The loss between NODE prediction \( h(T) \) and the ground truth is denoted by \( \mathcal{L}(h(T)) \); we update parameters \( \theta \) using the following gradient [Pontryagin, 2018]

\[
\frac{d\mathcal{L}(h(T))}{d\theta} = \int_{t_0}^{T} a(t) \frac{\partial f(h(t), t, \theta)}{\partial \theta} dt,
\]

where \( a(t) := \frac{\partial \mathcal{L}}{\partial h(t)} \) is the adjoint state, which satisfies the adjoint equation

\[
\frac{da(t)}{dt} = -a(t) \frac{\partial f(h(t), t, \theta)}{\partial h}.
\]

NODEs are flexible in learning from irregularly-sampled sequential data and particularly suitable for learning complex dynamical systems [Chen et al., 2018; Rubanova et al., 2019; Zhang et al., 2019; Norcliffe et al., 2020; Du et al., 2020; Kidger et al., 2020], which can be trained by efficient algorithms [Quaglino et al., 2020; Daulbæv et al., 2020; Zhuang et al., 2021]. NODE-based continuous generative models have computational advantages over the classical normalizing flows [Chen et al., 2018; Grathwohl et al., 2019; Yildiz et al., 2019; Finlay et al., 2020]. NODEs have also been generalized to neural stochastic differential equations, stochastic processes, and graph NODEs [Jia and Benson, 2019; Li et al., 2020; Poli et al., 2019; Tzen and Raginsky, 2019; Huang et al., 2020; Norcliffe et al., 2021]. The drawback of NODEs is also prominent. In many ML tasks, NODEs require very high NFEs in both training and inference, especially in high accuracy settings where a lower tolerance is needed. The NFEs increase rapidly with training; high NFEs reduce computational speed and accuracy of NODEs and can lead to blow-ups in the worst-case scenario [Grathwohl et al., 2019; Dupont et al., 2019; Massaroli et al., 2020; Norcliffe et al., 2020]. As an illustration, we train NODEs for CIFAR10 classification using the same model and experimental settings as in [Dupont et al., 2019], except using a tolerance of \( 10^{-5} \); Fig. 1 shows both forward and backward NFEs and the training time of different ODE-based models: we see that NFEs and computational times increase very rapidly for NODE, ANODE [Dupont et al., 2019], and SONODE [Norcliffe et al., 2020]. More results on the large NFE and degrading utility issues for different benchmark experiments are available in Sec. 5. Another issue is that NODEs often fail to effectively learn long-term dependencies in sequential data [Lechner and Hasani, 2020], discussed in Sec. 4.

### 1.1 Contribution

We propose heavy ball neural ODEs (HBNODEs), leveraging the continuous limit of the classical momentum accelerated gradient descent, to improve NODE training and inference. At the core of HBNODE is replacing the first-order ODE (1) with a heavy ball ODE (HBODE), i.e., a second-order ODE with an appropriate damping term. HBNODEs have two theoretical properties that imply practical advantages over NODEs:

- The adjoint equation used for training a HBNODE is also a HBNODE (see Prop. 1 and Prop. 2), accelerating both forward and backward propagation, thus significantly reducing both forward and backward NFEs. The reduction in NFE using HBNODE over existing benchmark ODE-based models becomes more aggressive as the error tolerance of the ODE solvers decreases.

- The spectrum of the HBODE is well-structured (see Prop. 4), alleviating the vanishing gradient issue in back-propagation and enabling the model to effectively learn long-term dependencies from sequential data.

To mitigate the potential blow-up problem in training HBNODEs, we further propose generalized HBNODEs (GHBNODEs) by integrating skip connections [He et al., 2016] and gating mechanisms [Hochreiter and Schmidhuber, 1997] into the HBNODE. See Sec. 5 for details.
1.2 Organization

We organize the paper as follows: In Secs. 2 and 3, we present our motivation, algorithm, and analysis of HBNODEs and GHBNODEs, respectively. We analyze the spectrum structure of the adjoint equation of HBNODEs/IGHBNODEs in Sec. 4, which indicates that HBNODEs/IGHBNODEs can learn long-term dependency effectively. We test the performance of HBNODEs and GHBNODEs on benchmark point cloud separation, image classification, learning dynamics, and sequential modeling in Sec. 5. We discuss more related work in Sec. 6, followed by concluding remarks. Technical proofs and more experimental details are provided in the appendix.

2 Heavy Ball Neural Ordinary Differential Equations

2.1 Heavy ball ordinary differential equation

Classical momentum method, a.k.a., the heavy ball method, has achieved remarkable success in accelerating gradient descent [Polyak 1964] and has significantly improved the training of deep neural networks [Sutskever et al. 2013]. As the continuous limit of the classical momentum method, heavy ball ODE (HBODE) has been studied in various settings and has been used to analyze the acceleration phenomenon of the momentum methods. For the ease of reading and completeness, we derive the HBODE from the classical momentum method. Starting from initial points \( x^0 \) and \( x^1 \), gradient descent with classical momentum searches a minimum of the function \( F(x) \) through the following iteration

\[
x^{k+1} = x^k - s \nabla F(x^k) + \beta (x^k - x^{k-1}),
\]

where \( s > 0 \) is the step size and \( 0 \leq \beta < 1 \) is the momentum hyperparameter. For any fixed step size \( s \), let \( m^k := (x^{k+1} - x^k) / \sqrt{s} \), and let \( \beta := 1 - \gamma \sqrt{s} \), where \( \gamma \geq 0 \) is another hyperparameter. Then we can rewrite (4) as

\[
m^{k+1} = (1 - \gamma \sqrt{s}) m^k - \sqrt{s} \nabla F(x^k); \quad x^{k+1} = x^k + \sqrt{s} m^{k+1}.
\]

Let \( s \to 0 \) in (5), we obtain the following system of first-order ODEs,

\[
\frac{dx(t)}{dt} = m(t); \quad \frac{dm(t)}{dt} = -\gamma m(t) - \nabla F(x(t)).
\]

This can be further rewritten as a second-order heavy ball ODE (HBODE), which also models a damped oscillator,

\[
\frac{d^2 x(t)}{dt^2} + \gamma \frac{dx(t)}{dt} = -\nabla F(x(t)).
\]

We compare the dynamics of HBODE (7) and the following ODE limit of the gradient descent (GD)

\[
\frac{dx}{dt} = -\nabla F(x).
\]

In particular, we solve the ODEs (7) and (8) with \( F(x) \) defined as a Rosenbrock [Rosenbrock 1960] or Beale [Gonçalves 1971] function (see Appendix E.6 for experimental details). Fig. 2 shows that with the same numerical ODE solver, HBODE converges to the stationary point (marked by stars) faster than (8). The fact that HBODE can accelerate the dynamics of the ODE for a gradient system motivates us to propose HBNODE to accelerate forward propagation of NODE.

2.2 Heavy ball neural ordinary differential equations

Similar to NODE, we parameterize \( -\nabla F \) in (7) using a neural network \( f(h(t), t, \theta) \), resulting in the following HBNODE with initial position \( h(t_0) \) and momentum \( m(t_0) := dh/dt(t_0) \),

\[
\frac{d^2 h(t)}{dt^2} + \gamma \frac{dh(t)}{dt} = f(h(t), t, \theta),
\]

where \( \gamma \geq 0 \) is the damping parameter, which can be set as a tunable or a learnable hyperparameter with positivity constraint. In the trainable case, we use \( \gamma = \epsilon \cdot \text{sigmoid}(\omega) \) for a trainable \( \omega \in \mathbb{R} \) and a fixed tunable upper bound \( \epsilon \) (we set \( \epsilon = 1 \) below). According to (9), HBNODE (9) is equivalent to

\[
\frac{dh(t)}{dt} = m(t); \quad \frac{dm(t)}{dt} = -\gamma m(t) + f(h(t), t, \theta).
\]
Therefore, the adjoint of the HBNODE is also a HBNODE and they have the same damping parameter.

We can also employ (10) and its adjoint for the forward and backward propagations, respectively.

**Proposition 2** (Adjoint equations for the first-order HBNODE system). The adjoint states \( a_h(t) := \partial L / \partial h(t) \) and \( a_m(t) := \partial L / \partial m(t) \) for the first-order HBNODE system (10) satisfy

\[
\frac{da_h(t)}{dt} = -a_m(t) \frac{\partial f}{\partial h}(h(t), t, \theta); \quad \frac{da_m(t)}{dt} = -a_h(t) + \gamma a_m(t).
\]

**Remark 2.** Let \( \tilde{a}_m(t) = da_m(t)/dt \), then \( a_m(t) \) and \( \tilde{a}_m(t) \) satisfies the following first-order heavy ball ODE system

\[
\frac{da_m(t)}{dt} = a_m(t); \quad \frac{d\tilde{a}_m(t)}{dt} = a_m(t) \frac{\partial f}{\partial h}(h(t), t, \theta) + \gamma \tilde{a}_m(t).
\]

Note that we solve this system backward in time in back-propagation. Moreover, we have \( a_h(t) = \gamma a_m(t) - \tilde{a}_m(t) \).

Similar to [Norcliffe et al., 2020], we use the coupled first-order HBNODE system (10) and its adjoint first-order HBNODE system (13) for practical implementation, since the entangled representation permits faster computation [Norcliffe et al., 2020] of the gradients of the coupled ODE systems.

### 3 Generalized Heavy Ball Neural Ordinary Differential Equations

In this section, we propose a generalized version of HBNODE (GHBNODE), see [15], to mitigate the potential blow-up issue in training ODE-based models. In our experiments, we observe that \( h(t) \) of ANODEs [Dupont et al., 2019], SONODEs [Norcliffe et al., 2020], and HBNODEs (11) usually grows much faster than that of NODEs. The fast growth of \( h(t) \) can lead to finite-time blow up. As an illustration, we compare the performance of NODE, ANODE, SONODE, HBNODE, and GHBNODE on the Silverbox task as in [Norcliffe et al., 2020]. The goal of the task is to learn the voltage of an electronic circuit that resembles a Duffing oscillator, where the input voltage \( V_1(t) \) is used to predict the output \( V_2(t) \). Similar to the setting in [Norcliffe et al., 2020], we first augment ANODE by 1 dimension with 0-augmentation and augment SONODE, HBNODE, and GHBNODE with a dense network. We use a simple dense layer to parameterize \( f \) for all five models, with an extra input term for \( V_1(t) \). For both HBNODE and GHBNODE, we set the damping parameter \( \gamma \) to be \( \text{sigmoid}(-3) \). For GHBNODE (15) below, we set \( \sigma(\cdot) \) to be the hardtanh function with bound \([-5, 5]\) and \( \xi = \ln(2) \).

The detailed architecture can be found in Appendix E. As shown in Fig. 3 compared to the vanilla

---

\(^3\)Here, we exclude an \( h^3 \) term that appeared in the original Duffing oscillator model because including it would result in finite-time explosion.
NODE, the ℓ2 norm of \( h(t) \) grows much faster when a higher order NODE is used, which leads to blow-up during training. Similar issues arise in the time series experiments (see Sec. 5.4), where SONODE blows up during long term integration in time, and HBNODE suffers from the same issue with some initialization.

To alleviate the problem above, we propose the following generalized HBNODE

\[
\begin{align*}
\frac{dh(t)}{dt} &= \sigma(m(t)), \\
\frac{dm(t)}{dt} &= -\gamma m(t) + f(h(t), t, \theta) - \xi h(t),
\end{align*}
\]  

(15)

where \( \sigma(\cdot) \) is a nonlinear activation, which is set as tanh in our experiments. The positive hyper-parameters \( \gamma, \xi > 0 \) are tunable or learnable. In the trainable case, we let \( \gamma = \epsilon \cdot \text{sigmoid}(\omega) \) as in HBNODE, and \( \xi = \text{softplus}(\chi) \) to ensure that \( \gamma, \xi \geq 0 \). Here, we integrate two main ideas into the design of GHBNODE: (i) We incorporate the gating mechanism used in LSTM [Hochreiter and Schmidhuber, 1997] and GRU [Cho et al., 2014], which can suppress the aggregation of \( m(t) \); (ii) Following the idea of skip connection [He et al., 2016], we add the term \( \xi h(t) \) into the governing equation of \( m(t) \), which benefits training and generalization of GHBNODEs. Fig. 3 shows that GHBNODE can indeed control the growth of \( h(t) \) effectively.

**Proposition 3** (Adjoint equations for GHBNODEs). The adjoint states \( a_h(t) := \partial L / \partial h(t), a_m(t) := \partial L / \partial m(t) \) for the GHBNODE (15) satisfy the following first-order ODE system

\[
\begin{align*}
\frac{\partial a_h(t)}{\partial t} &= -a_m(t) \left( \frac{\partial f}{\partial h}(h(t), t, \theta) - \xi I \right), \\
\frac{\partial a_m(t)}{\partial t} &= -a_h(t) \sigma'(m(t)) + \gamma a_m(t).
\end{align*}
\]  

(16)

Though the adjoint state of the GHBNODE (16) does not satisfy the exact heavy ball ODE, based on our empirical study, it also significantly reduces the backward NFEs.

### 4 Learning long-term dependencies – Vanishing gradient

It is known that the vanishing and exploding gradients are two bottlenecks for training recurrent neural networks (RNNs) with long-term dependencies [Bengio et al., 1994, Pascanu et al., 2013] (see Appendix C for a brief review on the exploding and vanishing gradient issues in training RNNs). The exploding gradients issue can be effectively resolved via gradient clipping, training loss regularization, etc [Pascanu et al., 2013, Erichson et al., 2021]. Thus in practice the vanishing gradient is the major issue for learning long-term dependencies [Pascanu et al., 2013]. As the continuous analogue of RNN, NODEs as well as their hybrid ODE-RNN models, may also suffer from vanishing in the adjoint state \( a(t) := \partial L / \partial h(t) \) [Lechner and Hasani, 2020]. When the vanishing gradient issue happens, \( a(t) \) goes to 0 quickly as \( T - t \) increases, then \( \partial L / \partial \theta \) in (2) will be independent of these \( a(t) \). We have the following expressions for the adjoint states of the NODE and HBNODE (see Appendix C for detailed derivation):

- For NODE, we have

\[
\frac{\partial L}{\partial h_i} = \frac{\partial L}{\partial h_T} \frac{\partial h_T}{\partial h_i} = \frac{\partial L}{\partial h_T} \exp \left\{ - \int_T^t \frac{\partial f}{\partial h}(h(s), s, \theta) ds \right\}.
\]  

(17)

- For GHBNODE\(^\text{4}\) from (13) we can derive

\[
\left[ \frac{\partial \sigma}{\partial m_T} \frac{\partial \sigma}{\partial m_T} \right] = \left[ \frac{\partial \sigma}{\partial m_T} \frac{\partial \sigma}{\partial m_T} \right] \exp \left\{ - \int_T^t \left( \frac{\partial f}{\partial h} \right)_t \left( \frac{\partial f}{\partial h} \right)_s - \xi I \right\} ds \right\}.
\]  

\[
:= M
\]  

(18)

Note that the matrix exponential is directly related to its eigenvalues. By Schur decomposition, there exists an orthogonal matrix \( Q \) and an upper triangular matrix \( U \), where the diagonal entries of \( U \) are eigenvalues of \( Q \) ordered by their real parts, such that

\[
-M = QUQ^T \implies \exp\{-M\} = Q \exp\{U\}Q^T.
\]  

(19)

\(^4\)HBNODE can be seen as a special GHBNODE with \( \xi = 0 \) and \( \sigma \) be the identity map.
Figure 4: Plot of the $\ell_2$-norm of the adjoint states for ODE-RNN and (G)HBNODE-RNN back-propagated from the last time stamp. The adjoint state of ODE-RNN vanishes quickly when the gap between the final time $T$ and intermediate time $t$ becomes larger, while the adjoint states of (G)HBNODE-RNN decays much more slowly. This implies that (G)HBNODE-RNN is more effective in learning long-term dependency than ODE-RNN.

Let $v^T := \left[ \frac{\partial C}{\partial h_T} \frac{\partial C}{\partial m_T} \right] Q$, then (18) can be rewritten as

$$\left[ \frac{\partial C}{\partial h_t} \frac{\partial C}{\partial m_t} \right] = \left[ \frac{\partial C}{\partial h_T} \frac{\partial C}{\partial m_T} \right] \exp(-M) \left[ \frac{\partial C}{\partial h_T} \frac{\partial C}{\partial m_T} \right] = Q \exp(U) Q^T = v^T \exp(U) Q^T. \quad (20)$$

By taking the $\ell_2$ norm in (20) and dividing both sides by $\| \left[ \frac{\partial C}{\partial h_T} \frac{\partial C}{\partial m_T} \right] \|_2$, we arrive at

$$\| \frac{\partial C}{\partial h_t} \frac{\partial C}{\partial m_t} \|_2 = \frac{\| v^T \exp(U) Q^T \|_2}{\| v^T \|_2} = \frac{\| v^T \exp(U) \|_2}{\| v \|_2} = \| e^T \exp(U) \|_2,$$

i.e., $\| \frac{\partial C}{\partial h_t} \frac{\partial C}{\partial m_t} \|_2 = \| e^T \exp(U) \|_2 \| \left[ \frac{\partial C}{\partial h_T} \frac{\partial C}{\partial m_T} \right] \|_2$ where $e = v / \| v \|_2$.

**Proposition 4.** The eigenvalues of $-M$ can be paired so that the sum of each pair equals $(t - T) \gamma$.

For a given constant $a > 0$, we can group the upper triangular matrix $\exp(U)$ as follows

$$\exp(U) := \begin{bmatrix} \exp(U_L) & P \\ 0 & \exp(U_V) \end{bmatrix}, \quad (22)$$

where the diagonal of $U_L (U_V)$ contains eigenvalues of $-M$ that are no less (greater) than $(t - T)a$. Then, we have $\| e^T \exp(U) \|_2 \geq \| e_L^T \exp(U_L) \|_2$ where the vector $e_L$ denotes the first $m$ columns of $e$ with $m$ be the number of columns of $U_L$. By choosing $0 \leq \gamma \leq 2a$, for every pair of eigenvalues of $-M$ there is at least one eigenvalue whose real part is no less than $(t - T)a$. Therefore, $\exp(U_L)$ decays at a rate at most $(t - T)a$, and the dimension of $U_L$ is at least $N \times N$. We avoid exploding gradients by clipping the $\ell_2$ norm of the adjoint states similar to that used for training RNNs.

In contrast, all eigenvalues of the matrix $\int_T^t \partial f / \partial h ds$ in (17) for NODE can be very positive or negative, resulting in exploding or vanishing gradients. As an illustration, we consider the benchmark Walker2D kinematic simulation task that requires learning long-term dependencies effectively [Lechner and Hasani, 2020, Brockman et al., 2016]. We train ODE-RNN [Rubanova et al., 2019] and (G)HBNODE-RNN on this benchmark dataset, and the detailed experimental settings are provided in Sec. 5.4. Figure 4 plots $\| \partial L / \partial h_t \|_2$ for ODE-RNN and $\| [\partial L / \partial h_t, \partial L / \partial m_t] \|_2$ for (G)HBNODE-RNN, showing that the adjoint state of ODE-RNN vanishes quickly, while that of (G)HBNODE-RNN does not vanish even when the gap between $T$ and $t$ is very large.

5 Experimental Results

In this section, we compare the performance of the proposed HBNODE and GHBNODE with existing ODE-based models, including NODE [Chen et al., 2018], ANODE [Dupont et al., 2019], and SONODE [Norcliffe et al., 2020] on the benchmark point cloud separation, image classification, learning dynamical systems, and kinematic simulation. For all the experiments, we use Adam [Kingma and Ba, 2014] as the benchmark optimization solver (the learning rate and batch size for each experiment are listed in Table 1) and Dormand–Prince-45 as the numerical ODE solver. For HBNODE and GHBNODE, we set $\gamma = \text{sigmoid} (\theta)$, where $\theta$ is a trainable weight initialized as $\theta = -3$. The network architecture used to parameterize $f(h(t), t, \theta)$ for each experiment below are described in Appendix E. All experiments are conducted on a server with 2 NVIDIA Titan Xp GPUs.
Table 1: The batch size and learning rate for different datasets.

| Dataset       | Point Cloud | MNIST | CIFAR10 | Plane Vibration | Walker2D |
|---------------|-------------|-------|---------|-----------------|----------|
| Batch Size    | 50          | 64    | 64      | 64              | 256      |
| Learning Rate | 0.01        | 0.001 | 0.001   | 0.0001          | 0.003    |

Figure 5: Comparison between NODE, ANODE, SONODE, HBNODE, and GHBNODE for two-dimensional point cloud separation. HBNODE and GHBNODE converge better and require less NFEs in both forward and backward propagation than the other benchmark models.

5.1 Point cloud separation

In this subsection, we consider the two-dimensional point cloud separation benchmark. A total of 120 points are sampled, in which 40 points are drawn uniformly from the circle $\|r\| < 0.5$, and 80 points are drawn uniformly from the annulus $0.85 < \|r\| < 1.0$. This experiment aims to learn effective features to classify these two point clouds. Following Dupont et al. [2019], we use a three-layer neural network to parameterize the right-hand side of each ODE-based model, integrate the ODE-based model from $t_0 = 0$ to $T = 1$, and pass the integration results to a dense layer to generate the classification results. We set the size of hidden layers so that the models have similar sizes, and the number of parameters of NODE, ANODE, SONODE, HBNODE, and GHBNODE are 525, 567, 528, 568, and 568, respectively. To avoid the effects of numerical error of the black-box ODE solver we set tolerance of ODE solver to be $10^{-7}$. Figure 5 plots a randomly selected evolution of the point cloud separation for each model; we also compare the forward and backward NFEs and the training loss of these models (100 independent runs). HBNODE and GHBNODE improve training as the training loss consistently goes to zero over different runs, while ANODE and SONODE often get stuck at local minima, and NODE cannot separate the point cloud since it preserves the topology [Dupont et al., 2019].

5.2 Image classification

We compare the performance of HBNODE and GHBNODE with the existing ODE-based models on MNIST and CIFAR10 classification tasks using the same setting as in Dupont et al. [2019]. We parameterize $f(h(t), t, \theta)$ using a 3-layer convolutional network for each ODE-based model, and the total number of parameters for each model is listed in Table 2. For a given input image of the size $c \times h \times w$, we first augment the number of channel from $c$ to $c + p$ with the augmentation dimension $p$ dependent on each method. Moreover, for SONODE, HBNODE and GHBNODE, we further include velocity or momentum with the same shape as the augmented state.

Table 2: The number of parameters for each models for image classification.

| Model               | NODE       | ANODE      | SONODE     | HBNODE     | GHBNODE    |
|---------------------|------------|------------|------------|------------|------------|
| #Params (MNIST)     | 85,315     | 85,462     | 86,179     | 85,931     | 85,235     |
| #Params (CIFAR10)   | 173,611    | 172,452    | 171,635    | 172,916    | 172,916    |

We set $p = 0, 5, 4, 4, 5/0, 10, 9, 9, 9$ on MNIST/CIFAR10 for NODE, ANODE, SONODE, HBNODE, and GHBNODE, respectively.
In this subsection, we learn dynamical systems from experimental measurements. In particular, we use the ODE-RNN framework [Chen et al., 2018; Rubanova et al., 2019], with the recognition model being set to different ODE-based models, to study the vibration of an airplane dataset [Noël and Schoukens, 2017]. The dataset was acquired, from time 0 to 73627, by attaching a shaker underneath the right wing to provide input signals, and 5 attributes are recorded per time stamp; these attributes include voltage of input signal, force applied to aircraft, and acceleration at 3 different spots of the airplane. We randomly take out 10% of the data to make the time series irregularly-sampled. We use the first 50% of data as our train set, the next 25% as validation set, and the rest as test set. We divide each set into non-overlapping segments of consecutive 65 time stamps of the irregularly-sampled time series, with each input instance consisting of 64 time stamps of the irregularly-sampled time series, and we aim to forecast 8 consecutive time stamps starting from the last time stamp of the segment. The input is fed through the the hybrid methods in a recurrent fashion; by changing the time duration

Figure 6: Contrasting NODE [Chen et al., 2018], ANODE [Dupont et al., 2019], SONODE [Norcliffe et al., 2020], HBNODE, and GHBNODE for MNIST classification in NFE, training time, and test accuracy. (Tolerance: $10^{-5}$).

**NFEs.** As shown in Figs. 1 and 6, the NFEs grow rapidly with training of the NODE, resulting in an increasingly complex model with reduced performance and the possibility of blow up. Input augmentation has been verified to effectively reduce the NFEs, as both ANODE and SONODE require fewer forward NFEs than NODE for the MNIST and CIFAR10 classification. However, input augmentation is less effective in controlling their backward NFEs. HBNODE and GHBNODE require much fewer NFEs than the existing benchmarks, especially for backward NFEs. In practice, reducing NFEs implies reducing both training and inference time, as shown in Figs. 1 and 6.

**Accuracy.** We also compare the accuracy of different ODE-based models for MNIST and CIFAR10 classification. As shown in Figs. 1 and 6, HBNODE and GHBNODE have slightly better classification accuracy than the other three models; this resonates with the fact that less NFEs lead to simpler models which generalize better [Dupont et al., 2019; Norcliffe et al., 2020].

Figure 7: NFE vs. tolerance (shown in the colorbar) for training ODE-based models for CIFAR10 classification. Both forward and backward NFEs of HBNODE and GHBNODE grow much more slowly than that of NODE, ANODE, and SONODE; especially the backward NFEs. As the tolerance decreases, the advantage of HBNODE and GHBNODE in reducing NFEs becomes more significant.

**NFEs vs. tolerance.** We further study the NFEs for different ODE-based models under different tolerances of the ODE solver using the same approach as in Chen et al. [2018]. Figure 7 depicts the forward and backward NFEs for different models under different tolerances. We see that (i) both forward and backward NFEs grow quickly when tolerance is decreased, and HBNODE and GHBNODE require much fewer NFEs than other models; (ii) under different tolerances, the backward NFEs of NODE, ANODE, and SONODE are much larger than the forward NFEs, and the difference becomes larger when the tolerance decreases. In contrast, the forward and backward NFEs of HBNODE and GHBNODE scale almost linearly with each other. This reflects that the advantage in NFEs of (G)HBNODE over the benchmarks become more significant when a smaller tolerance is used.

**5.3 Learning dynamical systems from irregularly-sampled time series**

In this subsection, we learn dynamical systems from experimental measurements. In particular, we use the ODE-RNN framework [Chen et al., 2018; Rubanova et al., 2019], with the recognition model being set to different ODE-based models, to study the vibration of an airplane dataset [Noël and Schoukens, 2017]. The dataset was acquired, from time 0 to 73627, by attaching a shaker underneath the right wing to provide input signals, and 5 attributes are recorded per time stamp; these attributes include voltage of input signal, force applied to aircraft, and acceleration at 3 different spots of the airplane. We randomly take out 10% of the data to make the time series irregularly-sampled. We use the first 50% of data as our train set, the next 25% as validation set, and the rest as test set. We divide each set into non-overlapping segments of consecutive 65 time stamps of the irregularly-sampled time series, with each input instance consisting of 64 time stamps of the irregularly-sampled time series, and we aim to forecast 8 consecutive time stamps starting from the last time stamp of the segment. The input is fed through the the hybrid methods in a recurrent fashion; by changing the time duration
of the last step of the ODE integration, we can forecast the output in the different time stamps. The output of the hybrid method is passed to a single dense layer to generate the output time series. In our experiments, we compare different ODE-based models hybrid with RNNs. The ODE of each model is parametrized by a 3-layer network whereas the RNN is parametrized by a simple dense network; the total number of parameters for ODE-RNN, ANODE-RNN, SONODE-RNN, HBNODE-RNN, and GHBNODE-RNN with 16, 22, 14, 15, 15 augmented dimensions are 15,986, 16,730, 16,649, 16,127, and 16,127, respectively. To avoid potential error due to the ODE solver, we use a tolerance of $10^{-7}$.

In training those hybrid models, we regularize the models by penalizing the L2 distance between the RNN output and the values of the next time stamp. Due to the second-order nature of the underlying dynamics [Norcliffe et al., 2020], ODE-RNN and ANODE-RNN learn the dynamics very poorly with much larger training and test losses than the other models even they take smaller NFEs. HBNODE-RNN and GHBNODE-RNN give better prediction than SONODE-RNN using less backward NFEs.

![Figure 8: Contrasting ODE-RNN, ANODE-RNN, SONODE-RNN, HBNODE-RNN, and GHBNODE-RNN for learning a vibrational dynamical system. Left most: The learned curves of each model vs. the ground truth (Time: <66 for training, 66-75 for testing).](image)

### 5.4 Walker2D kinematic simulation

In this subsection, we evaluate the performance of HBNODE-RNN and GHBNODE-RNN on the Walker2D kinematic simulation task, which requires learning long-term dependency effectively [Lechner and Hasani, 2020]. The dataset [Brockman et al., 2016] consists of a dynamical system from kinematic simulation of a person walking from a pre-trained policy, aiming to learn the kinematic simulation of the MuJoCo physics engine [Todorov et al., 2012]. The dataset is irregularly-sampled where 10% of data are removed from the simulation. Each input is consisted of 64 time stamps and fed through the the hybrid methods in a recurrent fashion, and the outputs of hybrid methods is passed to a single dense layer to generate the output time series. The target is to provide auto-regressive forecast so that the output time series is as close as the input sequence shifted 1 time stamp to the right. We compare ODE-RNN (with 7 augmentation), ANODE-RNN (with 7 ANODE style augmentation), HBNODE-RNN (with 7 augmentation), and GHBNODE-RNN (with 7 augmentation)\(^6\) The RNN is parametrized by a 3-layer network whereas the ODE is parametrized by a simple dense network. The number of parameters of the above four models are 8,729, 8,815, 8,899, and 8,899, respectively. In Fig.\(^5\) we compare the performance of the above four models on the Walker2D benchmark; HBNODE-RNN and GHBNODE-RNN not only require significantly less NFEs in both training (forward and backward) and in testing than ODE-RNN and ANODE-RNN, but also have much smaller training and test losses.

### 6 Related Work

**Reducing NFEs in training NODEs.** Several techniques have been developed to reduce the NFEs for the forward solvers in NODEs, including weight decay [Grathwohl et al., 2019], input augmentation [Dupont et al., 2019], regularizing solvers and learning dynamics [Finlay et al., 2020, Kelly et al., 2020, Ghosh et al., 2020, Pal et al., 2021], high-order ODE [Norcliffe et al., 2020], data control [Massaroli et al., 2020], and depth-variance [Massaroli et al., 2020]. HBNODEs can reduce both forward and backward NFEs at the same time.

**Second-order ODE accelerated dynamics.** It has been noticed in both optimization and sampling communities that second-order ODEs with an appropriate damping term, e.g., the classical momentum

---

\(^6\)Here, we do not compare with SONODE-RNN since SONODE has some initialization problem on this dataset, and the ODE solver encounters failure due to exponential growth over time. This issue is originally tackled by re-initialization [Norcliffe et al., 2020]. We re-initialized SONODE 100 times; all failed due to initialization problems.
Learning long-term dependencies. Learning long-term dependency is one of the most important goals for learning from sequential data. Most of the existing works focus on mitigating exploding or vanishing gradient issues in training RNNs, e.g., [Arjovsky et al., 2016; Wisdom et al., 2016; Jing et al., 2017; Vorontsov et al., 2017; Mhammedi et al., 2017; Heilrich et al., 2018; Tan M. Nguyen and Richard G. Baraniuk and Andrea L. Bertozzi and Stanley J. Osher and Bao Wang, 2020]. Attention-based models are proposed for learning on sequential data concurrently with the effective accommodation of learning long-term dependency [Vaswani et al., 2017; Devlin et al., 2018]. Recently, NODEs have been integrated with long-short term memory model [Hochreiter and Schmidhuber, 1997] to learn long-term dependency for irregularly-sampled time series [Lechner and Hasani, 2020]. HBNODEs directly enhance learning long-term dependency from sequential data.

Momentum in neural network design. As a line of orthogonal work, the momentum has also been studied in designing neural network architecture, e.g., [Moreau and Bruna, 2017; Tan M. Nguyen and Richard G. Baraniuk and Andrea L. Bertozzi and Stanley J. Osher and Bao Wang, 2020; Li et al., 2018; Sander et al., 2021], which can also help accelerate training and learn long-term dependencies. These techniques can be considered as changing the neural network $f$ in (1). We leave the synergistic integration of adding momentum to $f$ with our work on changing the left-hand side of (1) as a future work.

ResNet-style models. Interpreting ResNet as an ODE model has been an interesting research direction which has lead to interesting neural network architectures and analysis from the numerical ODE solvers and differential equation theory viewpoints, e.g., [Lu et al., 2018; Li et al., 2019; Wang et al., 2020].

7 Concluding Remarks

We proposed HBNODEs to reduce the NFEs in solving both forward and backward ODEs, which also improve generalization performance over the existing benchmark models. Moreover, HBNODEs alleviate vanishing gradients in training NODEs, making HBNODEs able to learn long-term dependency effectively from sequential data. In the optimization community, Nesterov acceleration [Nesterov, 1983] is also a famous algorithm for accelerating gradient descent, that achieves an optimal convergence rate for general convex optimization problems. The ODE counterpart of the Nesterov’s acceleration corresponds to (9) with $\gamma$ being replaced by a time-dependent damping parameter, e.g., $t/3$ [Su et al., 2014] or with restart [Wang et al., 2020a]. The adjoint equation of the Nesterov’s ODE [Su et al., 2014] is no longer a Nesterov’s ODE. We notice that directly using Nesterov’s ODE cannot improve the performance of the vanilla neural ODE. How to integrate Nesterov’s ODE with neural ODE is an interesting future direction. Another interesting direction is connecting HBNODE with symplectic ODE-net [Zhong et al., 2020] through an appropriate change of variables.

Checklist

1. For all authors...
   (a) Do the main claims made in the abstract and introduction accurately reflect the paper’s contributions and scope? [Yes]
   (b) Did you describe the limitations of your work? [Yes] See Section 4.1.
   (c) Did you discuss any potential negative societal impacts of your work? [N/A]
   (d) Have you read the ethics review guidelines and ensured that your paper conforms to them? [Yes]

2. If you are including theoretical results...
   (a) Did you state the full set of assumptions of all theoretical results? [Yes] See Section 4.1.
   (b) Did you include complete proofs of all theoretical results? [Yes] See Supplementary Materials

3. If you ran experiments...
   (a) Did you include the code, data, and instructions needed to reproduce the main experimental results (either in the supplemental material or as a URL)? [Yes]
   (b) Did you specify all the training details (e.g., data splits, hyperparameters, how they were chosen)? [Yes]
   (c) Did you report error bars (e.g., with respect to the random seed after running experiments multiple times)? [Yes]
   (d) Did you include the total amount of compute and the type of resources used (e.g., type of GPUs, internal cluster, or cloud provider)? [Yes]

4. If you are using existing assets (e.g., code, data, models) or curating/releasing new assets...
   (a) If your work uses existing assets, did you cite the creators? [Yes]
   (b) Did you mention the license of the assets? [Yes]
   (c) Did you include any new assets either in the supplemental material or as a URL? [N/A]
   (d) Did you discuss whether and how consent was obtained from people whose data you’re using/curating? [N/A]
   (e) Did you discuss whether the data you are using/curating contains personally identifiable information or offensive content? [N/A]

5. If you used crowdsourcing or conducted research with human subjects...
   (a) Did you include the full text of instructions given to participants and screenshots, if applicable? [N/A]
   (b) Did you describe any potential participant risks, with links to Institutional Review Board (IRB) approvals, if applicable? [N/A]
   (c) Did you include the estimated hourly wage paid to participants and the total amount spent on participant compensation? [N/A]
A Review of the Adjoint Equation for the First- and Second-order ODEs

The adjoint sensitivity method is the key to assuring constant memory usage in training neural ODEs [Chen et al., 2018]. In this section, we present two different proofs for the first-order adjoint sensitivity equations. The differentiation proof in Appendix A.1.1 is adapted from the proof by Norcliffe et al. [2020]. We provide a new integral proof in Appendix A.1.2 to extend theoretical support for the Lipschitz continuous functions. We also revisit the proof of the second-order adjoint sensitivity equations by Norcliffe et al. [2020].

A.1 First-order Adjoint Sensitivity Equation

A Neural ODE for hidden features \( h(t) \in \mathbb{R}^N \) takes the form

\[
\frac{\partial h}{\partial t} = f(h(t), t, \theta), \quad h(t_0) = h_{t_0}, \quad h(T) = h_T,
\]

where \( f(h(t), t, \theta) \in \mathbb{R}^N \) is a neural network with learnable parameters \( \theta \). The corresponding adjoint equation, with \( L \) being a scalar loss function, is defined by the following ODE,

\[
\frac{\partial A(t)}{\partial t} = -A(t) \frac{\partial f}{\partial h}, \quad A(T) = -I, \quad a(t) = -\frac{dL}{dh_T}A(t).
\]

For gradient-based optimization, we need to compute the following derivatives

\[
\frac{dL}{d\theta} = \frac{dL}{dh_T} \frac{dh_T}{d\theta}, \quad \frac{dL}{dh_{t_0}} = \frac{dL}{dh_T} \frac{dh_T}{dh_{t_0}}.
\]

In the following sections, we show that

\[
\frac{dh_T}{d\theta} = \int_0^T A \frac{\partial f}{\partial \theta} dt, \quad \frac{dh_T}{dh_{t_0}} = -A(t_0).
\]

By linearity, we immediately arrive at the following adjoint sensitivity equations

\[
\frac{dL}{d\theta} = \int_0^T A \frac{\partial f}{\partial \theta} dt, \quad \frac{dL}{dh_{t_0}} = a(t_0).
\]

A.1.1 Proof of the First-Order Adjoint Sensitivity Equation: Differentiation Approach

We adapt the proof of the adjoint sensitivity equations from Norcliffe et al. [2020]. Assume that \( f \in C^1 \), \( \phi \) is either \( \theta \) or \( h_{t_0} \), then the following equations hold

\[
\frac{\partial A(t)}{\partial t} = -A(t) \frac{\partial f}{\partial h}, \quad \frac{\partial^2 h}{\partial \phi \partial t} = \frac{\partial f}{\partial \theta} \frac{\partial h}{\partial \phi} + f \frac{\partial}{\partial t} \frac{\partial h}{\partial \phi}, \quad \frac{\partial}{\partial t} \frac{\partial A}{\partial \phi} = \frac{\partial A}{\partial t} \frac{\partial h}{\partial \phi} + A \frac{\partial^2 h}{\partial \phi \partial t}. \tag{28}
\]

Combining the three equations in (28) yields the differential equation

\[
\frac{\partial}{\partial t} \frac{\partial h}{\partial \phi} + A \frac{\partial}{\partial t} \frac{\partial h}{\partial \phi} = -A(t) \frac{\partial f}{\partial h} \frac{\partial h}{\partial \phi} + f \left( \frac{\partial}{\partial \phi} \frac{\partial h}{\partial \phi} + \frac{\partial}{\partial \phi} \frac{\partial h}{\partial \phi} \right) = A \frac{\partial f}{\partial \phi} \frac{\partial h}{\partial \phi}. \tag{29}
\]

Integrating both sides of (29) in \( t \) from \( T \) to \( t_0 \), we arrive at the integral equation

\[
\left( A \frac{\partial h}{\partial \phi} \right)_{t_0}^T = \int_T^{t_0} A \frac{\partial f}{\partial \phi} dt. \tag{30}
\]

Using the conditions \( A(T) = -I, \ h(t_0) = h_{t_0}, \ h(T) = h_T \), we rewrite the equation (30) as

\[
\frac{dh_T}{d\phi} = -A(t_0) \frac{dh_{t_0}}{d\phi} + \int_T^{t_0} A \frac{\partial f}{\partial \phi} dt. \tag{31}
\]

Substituting \( \phi = h_{t_0} \) and \( \phi = \theta \) respectively in (31) leads to

\[
\frac{dh_T}{dh_{t_0}} = -A(t_0), \quad \frac{dh_T}{d\theta} = \int_T^{t_0} A \frac{\partial f}{\partial \theta} dt. \tag{32}
\]

This proof is adapted from the proof provided by Norcliffe et al. [2020] for general second-order neural ODEs by differentiation and this proof only holds for \( f \in C^1 \).
A.1.2 Proof of the First-Order Adjoint Sensitivity Equations: Integration Approach

The proof in Appendix A.1.1 requires that \( f \in C^1 \). However, with activation functions like ReLU, \( f \) may not be smooth enough to satisfy this requirement. Meanwhile, the adjoint equation (32) guarantees that \( A \) may not have a continuous right hand side, which can fail the Picard-Lindelöf theorem that guarantees the existence and uniqueness of solutions to the adjoint equation.

To circumvent these deficiencies, we propose a new proof based on integration. Assume that \( f(h, t, \theta) \) is continuous in \( t \) and Lipschitz continuous in \( h, \theta \), and there exists some open ball around \( h_{t_0} = s_0 \), \( \theta = \theta_0 \) such that for every pair of initial condition and parameters in the open ball, there exists a unique solution for \( t \in [t_0, T] \). We denote the solution starting from \( h_{t_0} = s_0, \theta = \theta_0 \) as \( h_\theta \). In order to avoid difficulties in proving the existence and uniqueness of the solution, we explicitly define the adjoint equation through the following matrix exponential

\[
A(t) = -\exp\left\{-\int_t^T \frac{\partial f}{\partial h}(h_\theta(\tau), \tau, \theta_0) d\tau\right\}. \quad (33)
\]

By definition, \( A \) is Lipschitz continuous and satisfies the differential equation almost everywhere

\[
\frac{dA(t)}{dt} = -A(t) \frac{\partial f}{\partial h}(h_\theta(t), t, \theta_0). \quad (34)
\]

Since \( h \in C^1(t) \) and \( \frac{dA}{dt} \in L^1(t) \), we obtain the following using integration by parts,

\[
A(t) = \int_{t_0}^T A \frac{\partial h}{\partial t} dt + \int_{t_0}^T \frac{dA}{dt} h dt. \quad (35)
\]

Taking partial derivatives with respect to \( \phi \) on both sides of (35), as \( A(t) \) is only a function of \( t \), we have

\[
A \frac{\partial h}{\partial t} \bigg|_{t_0}^T = \frac{\partial}{\partial \phi} \int_{t_0}^T A \frac{\partial h}{\partial t} dt + \frac{\partial}{\partial \phi} \int_{t_0}^T \frac{dA}{dt} h dt. \quad (36)
\]

In order to exchange integral and derivatives, we use the dominated convergence theorem. Because \( f \) is Lipschitz continuous on \( h, \th ) \) is Lipschitz continuous on \( \phi \), and thus \( h_{\phi} \) is Lebesgue integrable. Therefore, by chain rule, the following equation holds almost everywhere,

\[
\frac{\partial h}{\partial t} = \frac{\partial h}{\partial \phi} \frac{\partial \phi}{\partial t} = \frac{\partial f}{\partial h} \frac{\partial h}{\partial \phi} + \frac{\partial f}{\partial \phi} \frac{\partial h}{\partial \phi}. \quad (37)
\]

Because \( t \) is bounded, the right hand side of equation (37) is Lebesgue integrable, and so is the left hand side. Because both \( h_{\phi} \) and \( \frac{\partial f}{\partial \phi} \frac{\partial h}{\partial \phi} \) are Lebesgue integrable, by dominated convergence theorem, we have the following exchange of integrals and derivatives

\[
\frac{\partial}{\partial \phi} \int_{t_0}^T A \frac{\partial h}{\partial t} dt = \int_{t_0}^T A \frac{\partial^2 h}{\partial t \partial \phi} dt, \quad \frac{\partial}{\partial \phi} \int_{t_0}^T \frac{dA}{dt} h dt = \int_{t_0}^T \frac{dA}{dt} \frac{\partial h}{\partial \phi} dt. \quad (38)
\]

Combining equation (36) with (38) gives us

\[
A \frac{\partial h}{\partial t} \bigg|_{t_0}^T = \int_{t_0}^T A \frac{\partial^2 h}{\partial t \partial \phi} dt + \int_{t_0}^T \frac{dA}{dt} \frac{\partial h}{\partial \phi} dt. \quad (39)
\]

By taking Lebesgue integral of equation (37), we have the equation

\[
\int_{t_0}^T A \frac{\partial^2 h}{\partial t \partial \phi} dt = \int_{t_0}^T \left( \frac{\partial f}{\partial h} \frac{\partial h}{\partial \phi} + \frac{\partial f}{\partial \phi} \frac{\partial h}{\partial \phi} \right) dt. \quad (40)
\]

Meanwhile, at \( h_0 \), we can integrate equation (34) to a similar form as

\[
\int_{t_0}^T \frac{dA}{dt} \frac{\partial h}{\partial \phi} dt = - \int_{t_0}^T A \frac{\partial f}{\partial h} \frac{\partial h}{\partial \phi} dt. \quad (41)
\]

Consequently, at \( h_0 \), we can sum up equations (39), (40), and (41) and arrive at

\[
A \frac{\partial h}{\partial t} \bigg|_{t_0}^T = \int_{t_0}^T A \frac{\partial f}{\partial h} \frac{\partial h}{\partial \phi} dt, \quad (42)
\]

which is the same integral equation as equation (30) in the differentiation proof in Appendix A.1.1. Thus, plugging in the initial conditions provides us with the same result.
A.1.3 Corollary of the First-order Gradient Propagation

An immediate corollary of the above proof is that combining equations (26) and (33) results in

\[
\frac{dh_T}{dh_{t_0}} = -A(t_0) = \exp\Bigg\{ - \int_{T}^{t_0} \frac{\partial f}{\partial h}(h_0(\tau), \tau, \theta_0) d\tau \Bigg\}. \tag{43}
\]

As (43) is true for every choice of \( t_0 \), we can also generalize it to

\[
\frac{dh_T}{dh_t} = \exp\Bigg\{ - \int_{T}^{t} \frac{\partial f}{\partial h}(h_0(\tau), \tau, \theta_0) d\tau \Bigg\}, \tag{44}
\]

which shows the relative gradient between different times in integral.

A.2 Second-order Adjoint Sensitivity Equation

A SONODE satisfies the following equations

\[
\begin{align*}
\frac{\partial h}{\partial t} &= v, \\
\frac{\partial v}{\partial t} &= f(h(t), v(t), t, \theta), \quad h(t_0) = h_{t_0}, \quad v(t_0) = v_{t_0},
\end{align*} \tag{45}
\]

which can be viewed as a coupled first-order ODE system of the form

\[
\begin{bmatrix}
\frac{\partial h}{\partial t} \\
\frac{\partial v}{\partial t}
\end{bmatrix} =
\begin{bmatrix}
\frac{\partial f}{\partial h} \\
\frac{\partial f}{\partial v}
\end{bmatrix}, \quad
\begin{bmatrix}
h(t) \\
v(t)
\end{bmatrix}(t_0) =
\begin{bmatrix}
h_{t_0} \\
v_{t_0}
\end{bmatrix}. \tag{46}
\]

Denote \( z = \begin{bmatrix} h \\ v \end{bmatrix} \) and final state as

\[
\begin{bmatrix}
h(T) \\
v(T)
\end{bmatrix} =
\begin{bmatrix}
h_T \\
v_T
\end{bmatrix} = z_T. \tag{47}
\]

Using the conclusions from Appendix A.1 then the adjoint equation is given by

\[
\frac{\partial A(t)}{\partial t} = -A(t) \begin{bmatrix} 0 & I \\ \frac{\partial f}{\partial h} & \frac{\partial f}{\partial v} \end{bmatrix}, \quad A(T) = -I, \quad a(t) = -\frac{dL}{dz_T} A(t). \tag{48}
\]

By rewriting \( A = \begin{bmatrix} A_h & A_v \end{bmatrix} \), we have the following differential equations

\[
\begin{align*}
\frac{\partial A_h(t)}{\partial t} &= -A_v(t) \frac{\partial f}{\partial h}, \\
\frac{\partial A_v(t)}{\partial t} &= -A_h(t) - A_v(t) \frac{\partial f}{\partial v},
\end{align*} \tag{49}
\]

with initial conditions

\[
A_h(T) = - \begin{bmatrix} I \\ 0 \end{bmatrix}, \quad A_v(T) = - \begin{bmatrix} 0 \\ I \end{bmatrix}, \tag{50}
\]

and adjoint states

\[
a_h(t) = \frac{dL}{dz_T} A_h(t), \quad a_v(t) = \frac{dL}{dz_T} A_v(t). \tag{51}
\]

The gradient equations becomes

\[
\frac{dL}{d\theta} = \int_{t_0}^{T} a \begin{bmatrix} 0 & \frac{\partial f}{\partial h} \\ \frac{\partial f}{\partial v} & 0 \end{bmatrix} dt = \int_{t_0}^{T} a_v \frac{\partial f}{\partial h} dt, \quad \frac{dL}{dh_{t_0}} = a_h(t_0), \quad \frac{dL}{dv_{t_0}} = a_v(t_0). \tag{52}
\]

In SONODE, \( h_{t_0} \) is fixed, and thus \( a_h \) disappears in gradient computation. Therefore, we are only interested in \( a_v \). Thus the adjoint \( A_v \) satisfies the following second-order ODE

\[
\frac{\partial^2 A_v(t)}{\partial t^2} = A_v(t) \frac{\partial f}{\partial h} - \partial (A_v(t) \frac{\partial f}{\partial h}) \frac{\partial f}{\partial v} \tag{53}
\]
and thus
\[ \frac{\partial^2 a_v(t)}{\partial t^2} = a_v(t) \frac{\partial f}{\partial h} - \frac{\partial (a_v(t) \frac{\partial f}{\partial v})}{\partial t}, \] (54)
with initial conditions
\[ a_v(T) = -\frac{dL}{dz} A_v(T) = \frac{dL}{dv_T}, \quad \frac{\partial a_v(T)}{\partial t} = -\frac{dL}{dh_T} - a_v(T) \frac{\partial f}{\partial v}(T). \] (55)
This proves the second order adjoint equations for \( a_v \).

B Proof of Propositions 1, 2, and 3

B.1 Proof of Adjoint Equation for HBNODE (Proposition 1)
As HBNODE takes the form
\[ \frac{d^2 h(t)}{dt^2} + \gamma \frac{dh(t)}{dt} = f(h(t), t, \theta), \] (56)
which can also be viewed as a SONODE. By applying the adjoint equation of SONODE (54), we arrive at
\[ \frac{\partial^2 a(t)}{\partial t^2} = a(t) \frac{\partial f}{\partial h} + \gamma \frac{\partial a(t)}{\partial t}. \] (57)
As HBNODE only carries its state \( h \) to the loss \( L \), we have \( \frac{dL}{dv_T} = 0 \), and thus the initial conditions in equation (55) become
\[ a(T) = 0, \quad \frac{\partial a(T)}{\partial t} = -\frac{dL}{dh_T}. \] (58)

B.2 Proof of Adjoint Equation for First-order HBNODE (Proposition 2)
The coupled form of HBNODE is a coupled first-order ODE system of the form
\[ \frac{\partial}{\partial t} \begin{bmatrix} h \\ m \end{bmatrix} = \begin{bmatrix} \gamma m + f(h(t), t, \theta) \\ h \\ m \end{bmatrix} \begin{bmatrix} h \\ m \end{bmatrix} (t_0) = \begin{bmatrix} h_{0t} \\ m_{0t} \end{bmatrix}. \] (59)
Denote the final state as
\[ \begin{bmatrix} h(T) \\ m(T) \end{bmatrix} = \begin{bmatrix} h_T \\ m_T \end{bmatrix} = z. \] (60)
Using the conclusions from Appendix A.1 we have the adjoint equation
\[ \frac{\partial A(t)}{\partial t} = -A(t) \begin{bmatrix} 0 & I \\ \frac{\partial f}{\partial h} & -\gamma \frac{\partial f}{\partial h} \end{bmatrix}, \quad A(T) = -I, \quad a(t) = -\frac{dL}{dz} A(t). \] (61)
Let \( [a_h \quad a_m] = a \), by linearity we have
\[ \frac{\partial [a_h \quad a_m]}{\partial t} = -[a_h \quad a_m] \begin{bmatrix} 0 & I \\ \frac{\partial f}{\partial h} & -\gamma \frac{\partial f}{\partial h} \end{bmatrix}, \quad \begin{bmatrix} a_h(T) \\ a_m(T) \end{bmatrix} = \begin{bmatrix} \frac{dL}{dz_T} \\ \frac{dL}{dm_T} \end{bmatrix}, \] (62)
which gives us the initial conditions at \( t = T \), and the simplified first-order ODE system
\[ \frac{\partial a_h}{\partial t} = -a_m \frac{\partial f}{\partial h}, \quad \frac{\partial a_m}{\partial t} = -a_h + \gamma a_m. \] (63)
B.3 Proof of Adjoint Equation for GHBNODE (Proposition 3)

The coupled form of GHBNODE is a first-order ODE system of the form

$$\frac{\partial}{\partial t} \begin{bmatrix} h \\ m \end{bmatrix} = \begin{bmatrix} \sigma(m) \\ -\gamma m + f(h(t), t, \theta) - \xi h(t) \end{bmatrix}, \quad \begin{bmatrix} h \\ m \end{bmatrix}(t_0) = \begin{bmatrix} h_{t_0} \\ m_{t_0} \end{bmatrix}. \quad (64)$$

Denote the final state as

$$\begin{bmatrix} h(T) \\ m(T) \end{bmatrix} = \begin{bmatrix} h_T \\ m_T \end{bmatrix} = z_T. \quad (65)$$

Using the conclusions from Appendix A.1 we have the adjoint equation

$$\frac{\partial A(t)}{\partial t} = -A(t) \begin{bmatrix} 0 \\ \xi I \end{bmatrix}, \quad A(T) = -I, \quad a(t) = -\frac{dL}{dz_T} A(t). \quad (66)$$

Let \([a_h \quad a_m] = a\), by linearity we have

$$\frac{\partial [a_h \quad a_m]}{\partial t} = -[a_h \quad a_m] \begin{bmatrix} 0 \\ \xi I \end{bmatrix}, \quad [a_h(T) \quad a_m(T)] = \begin{bmatrix} \frac{\partial L}{\partial h_T} \\ \frac{\partial L}{\partial m_T} \end{bmatrix}, \quad (67)$$

which gives us the initial conditions at \(t = T\), and the simplified first-order ODE system

$$\frac{\partial a_h}{\partial t} = -a_m \left( \frac{\partial f}{\partial h} - \xi I \right), \quad \frac{\partial a_m}{\partial t} = -a_h \sigma'(m) + \gamma a_m. \quad (68)$$

C Vanishing and Exploding Gradients in Training RNNs

Recurrent cells are the building blocks of RNNs. A recurrent cell can be mathematically written as

$$h_t = \sigma(U h_{t-1} + W x_t + b), \quad x_t \in \mathbb{R}^d, \quad \text{for } t = 1, 2, \cdots, T, \quad (69)$$

where \(h_t \in \mathbb{R}^h\) is the hidden state, \(U \in \mathbb{R}^{h \times h}, W \in \mathbb{R}^{h \times d}\), and \(b \in \mathbb{R}^h\) are trainable parameters; \(\sigma(\cdot)\) is a nonlinear activation function, e.g., sigmoid. Backpropagation through time is a popular algorithm for training RNNs, which usually results in exploding or vanishing gradients [Bengio et al., 1994]. Thus RNNs may fail to learn long term dependencies. As an illustration, let \(h_T\) and \(h_t\) be the state vectors at the timestamps \(T\) and \(t\) \((T \gg t)\), respectively. Assume \(L\) is the loss to minimize, then

$$\frac{\partial L}{\partial h_t} = \frac{\partial L}{\partial h_T} \cdot \frac{\partial h_T}{\partial h_t} = \frac{\partial L}{\partial h_T} \cdot \prod_{k=t}^{T-1} \frac{\partial h_{k+1}}{\partial h_k} = \frac{\partial L}{\partial h_T} \cdot \prod_{k=t}^{T-1} (D_k U^\top), \quad (70)$$

where \(D_k = \text{diag}(\sigma'(U h_k + W x_{k+1}))\) is a diagonal matrix with \(\sigma'(U h_k + W x_{k+1})\) being its diagonal entries. \(\prod_{k=t}^{T-1}(D_k U^\top)\) tends to either vanish or explode [Bengio et al., 1994].

When applying RNNs to sequence applications with \(x = (x_1, \cdots, x_T)\) be an input sequence of length \(T\) and \(y = (y_1, \cdots, y_T)\) be the sequence of labels, we let \(L_t\) be the loss at the timestamp \(t\) and the total loss on the whole sequence be

$$\mathcal{L} = \sum_{t=1}^{T} L_t, \quad (71)$$

the vanishing or exploding issue can be shown following (70).

For neural ODEs, note that the adjoint state \(a(t)\) is defined as \(\partial L / \partial h(t)\), which also tends to explode or vanish during training.
C.1 Derivation of equation (18)

GHBNODE can be viewed as a system of higher dimensional NODE as in equation (64). With \( z = \begin{bmatrix} h \\ m \end{bmatrix} \), \( z \) satisfies NODE equation, and therefore it also satisfies the equation for relative gradient information as in (44),

\[
\frac{dz_T}{dz_t} = \exp \left\{ - \int_{T}^{t} \frac{\partial f}{\partial z} (z_0(\tau), \tau, \theta_0) d\tau \right\}.
\]

(72)

By definition of multivariate derivatives, we have

\[
\frac{dz_T}{dz_t} = \begin{bmatrix}
\frac{\partial h_T}{\partial h_t} & \frac{\partial h_T}{\partial m_t} \\
\frac{\partial m_T}{\partial h_t} & \frac{\partial m_T}{\partial m_t}
\end{bmatrix},
\]

(73)

and

\[
\frac{\partial f}{\partial z} = \begin{bmatrix} 0 \\ \frac{\partial \sigma}{\partial m} \end{bmatrix} - \xi I - \gamma I.
\]

(74)

With equations (73) and (74), we can rewrite equation (72) in terms of \( h \) and \( m \) as

\[
\begin{bmatrix}
\frac{\partial h_T}{\partial h_t} & \frac{\partial h_T}{\partial m_t} \\
\frac{\partial m_T}{\partial h_t} & \frac{\partial m_T}{\partial m_t}
\end{bmatrix} = \exp \left\{ - \int_{T}^{t} \begin{bmatrix} 0 \\ \frac{\partial \sigma}{\partial m} \end{bmatrix} - \xi I - \gamma I \right\} ds.
\]

(75)

In particular, since HBNODEs are GHBNODEs with \( \xi = 0 \) and \( \sigma \) being the identity map, the gradient equation of HBNODEs takes the form

\[
\begin{bmatrix}
\frac{\partial h_T}{\partial h_t} & \frac{\partial h_T}{\partial m_t} \\
\frac{\partial m_T}{\partial h_t} & \frac{\partial m_T}{\partial m_t}
\end{bmatrix} = \exp \left\{ - \int_{T}^{t} \begin{bmatrix} 0 \\ I \end{bmatrix} - \gamma I \right\} ds.
\]

(76)

This concludes the derivation of equation (18).

D Proof of Proposition 4

Proof. Let \( F = \frac{1}{t-T} \int_{T}^{t} \frac{\partial f}{\partial h} (h(s), s, \theta) ds - \xi I \), \( J = \frac{1}{t-T} \int_{T}^{t} \frac{\partial \sigma}{\partial m} (m(s)) ds \), and \( H = \frac{1}{t-T} M \), then we have the following equation

\[
H = \frac{1}{t-T} M = \begin{bmatrix} 0 & J \\ F & -\gamma I \end{bmatrix}.
\]

(77)

As \(( \lambda + \gamma )I \) commutes with any matrix \( F \), the characteristics polynomials of \( H \) and \( JF \) satisfy the relation

\[
ch_H(\lambda) = det(\lambda I - H) = det \begin{bmatrix} \lambda I & -J \\ -F & (\lambda + \gamma)I \end{bmatrix} = det(\lambda(\lambda + \gamma)I - JF) = -ch_{JF}(\lambda(\lambda + \gamma)).
\]

(78)

Since the characteristics polynomial of \( JF \) splits in the field \( \mathbb{C} \) of complex numbers, i.e. \( ch_{JF}(x) = \prod_{i=1}^{n} (x - \lambda_{JF,i}) \), we have

\[
ch_H(\lambda) = -ch_{JF}(\lambda(\lambda + \gamma)) = - \prod_{i=1}^{n} (\lambda(\lambda + \gamma) - \lambda_{JF,i}).
\]

(79)

Therefore, the eigenvalues of \( H \) appear in \( n \) pairs with each pair satisfying the quadratic equation

\[
\lambda(\lambda + \gamma) - \lambda_{JF,i} = 0.
\]

(80)

By Vieta's formulas, the sum of these pairs are all \( -\gamma \). Therefore, the eigenvalues of \( M \) comes in \( n \) pairs and the sum of each pair is \( -(t-T)\gamma \). \( \square \)
E Experimental details

We first list some common settings below:

- NODE and ANODE do not have initial layers.
- For SONODE $n^* = 2n$, and for other ones $n^* = n$.
- Hyper parameters are listed in Table 3.
- HTanh: HardTanh(-5, 5)
- LReLU: LeakyReLU(0.3)
- tpad: Padding with time $t$ within ODE, i.e., transform the shape $c \times x \times y$ to $(c+1) \times x \times y$ by concatenating with a tensor of shape $1 \times x \times y$ filled with all $t$.
- For all tasks, we use learnable $\gamma$ with $\epsilon = 1$ for both HBNODE and GHBNODE, and learnable $\xi$.
- $fc_n$: a fully connected layer with output dimension to be $n$.

| Model       | NODE | ANODE | SONODE | HBNODE | GHBNODE |
|-------------|------|-------|--------|--------|---------|
| $n$ (Initialization) | 1    | 2     | 1      | 1      | 1       |

E.1 Network architecture used in Section 3 Initialization Test

- ODE : $input_{n^*+1} \rightarrow fc_n$

E.2 Experimental details for 5.1

- Initial Velocity : $input_2 \rightarrow fc_h \rightarrow HTanh \rightarrow fc_h \rightarrow HTanh \rightarrow fc_n$
- ODE : $input_{n^*} \rightarrow fc_h \rightarrow ELU \rightarrow fc_h \rightarrow ELU \rightarrow fc_n$
- Output : $input_n \rightarrow fc_1 \rightarrow Tanh$

E.3 Experimental details for 5.2

E.3.1 MNIST

- Initial Velocity : $input_{1 \times 28 \times 28} \rightarrow conv_{h,1} \rightarrow LReLU \rightarrow conv_{h,3} \rightarrow LReLU \rightarrow conv_{2n-1,1}$
- ODE : $input_{n^* \times 28 \times 28} \rightarrow tpad \rightarrow conv_{h,1} \rightarrow RelU \rightarrow tpad \rightarrow conv_{h,3} \rightarrow RelU \rightarrow tpad \rightarrow conv_{n,1}$
- Output : $input_{n \times 28 \times 28} \rightarrow fc_{10}$
E.3.2 CIFAR

• Initial Velocity: \(\text{input}_{3 \times 28 \times 28} \rightarrow \text{conv}_{h,1} \rightarrow \text{LReLU} \rightarrow \text{conv}_{h,3} \rightarrow \text{LReLU} \rightarrow \text{conv}_{2n - 3,1}\)

• ODE: \(\text{input}_{n \times 32 \times 32} \rightarrow \text{tpad} \rightarrow \text{conv}_{h,1} \rightarrow \text{ReLU} \rightarrow \text{tpad} \rightarrow \text{conv}_{h,3} \rightarrow \text{ReLU} \rightarrow \text{tpad} \rightarrow \text{conv}_{n,1}\)

• Output: \(\text{input}_{n \times 32 \times 32} \rightarrow \text{fc}_{10}\)

E.4 Experimental details for 5.3

• ODE: \(\text{input}_{n} \rightarrow \text{fc}_{h,1} \rightarrow \text{ReLU} \rightarrow \text{fc}_{h,2} \rightarrow \text{ReLU} \rightarrow \text{fc}_{n}\)

• RNN: \(\text{input}_{dn + k} \rightarrow \text{fc}_{dn}\)

• Output: \(\text{input}_{n} \rightarrow \text{fc}_{5}\)

E.5 Experimental details for 5.4

• ODE: \(\text{input}_{n} \rightarrow \text{fc}_{n}\)

• RNN: \(\text{input}_{dn + k} \rightarrow \text{fc}_{h,1} \rightarrow \text{Tanh} \rightarrow \text{fc}_{h,2} \rightarrow \text{Tanh} \rightarrow \text{fc}_{dn}\)

• Output: \(\text{input}_{n} \rightarrow \text{fc}_{17}\)

E.6 Experimental details for ODE vs. HBODE on benchmarks

To numerically show that the HBODE\(^{(7)}\) converges faster to the stationary point than the ODE limit of gradient descent\(^{(8)}\), we apply the Dormand–Prince-45 ODE solver, which is the default solver for NODEs, to solve both ODEs. We set \(F(x)\) to be two celebrated functions used in the optimization community, namely, the Rosenbrock and the Beale functions.

Rosenbrock function. The Rosenbrock function is given by
\[
F(x) := F(x, y) = 100(y - x^2)^2 + (1 - x)^2,
\]
which has the minimum \((x, y) = (1, 1)\). Starting from \((0, 0)\), we apply Dormand–Prince-45 solver using a step size \(\Delta t = 0.001\) to solve both ODEs\(^{(7)}\) and \(^{(8)}\) for \(t\) from 0 to 1. For the HBODE, we set \(\gamma = 0.9\) and set the initial value of \(dx/dt = (0, 0)\).

Beale function. The Beale function is given by
\[
F(x, y) = (1.5 - x + xy)^2 + (2.25 - x + xy^2)^2 + (2.625 - x + xy^3)^2
\]
which has the minimum \((x, y) = (3, 0.5)\). Starting from \((0, 0)\), we apply Dormand–Prince-45 solver using a step size 0.01 to solve both ODEs in\(^{(7)}\) and \(^{(8)}\) for \(t\) from 0 to 2. For the HBODE, we set \(\gamma = 0.7\) and set the initial value of \(dx/dt = (0, 0)\).
