ABSTRACT

This research was aimed to analyze vitamin E and C supplementation in feed on meat quality, thiobarbituric acid reactive substances (TBARS) and myoglobin level of muscovy duck. This research used 84 Indonesian muscovy duck divided into 7 group of experimental diet, namely E0C0 : basal feed without vitamin E and C supplementation, E400 : basal feed with 400 IU of vitamin E supplementation, E600 : basal feed with 600 IU of vitamin E supplementation, C400 : basal feed with 400 mg of vitamin C supplementation, C600 : basal feed with 600 mg of vitamin C supplementation, E200C200 : basal feed with 200 IU of vitamin E and 200 mg of vitamin C supplementation, E300C300 : basal feed with 300 IU of vitamin E and 300 mg of vitamin C. A completely randomized design was applied and each treatment had 4 replications. The data were analyzed using analysis of variance. Analysis of variance showed that treatments significantly affect (P<0.01) meat quality, myoglobin level and TBARS level. Vitamin E and C was proven able to improve final pH of muscovy duck meat. Supplementation of 300 IU of vitamin E and 300 mg of vitamin C at feed with 21% of protein and 3100 kcal/kg of energy could improve DIA, cooking loss, flavor, and color of muscovy duck meat; however, the highest meat tenderness was resulted from 400 IU vitamin E supplementation.

Keywords: myoglobin, volatile compounds, meat quality

Muscovy Duck Suplemented By Vitamin E and C in Feed (E. Tugiyanti et al.) 37
INTRODUCTION

Indonesian muscovy ducks, widely found in Java Island, are commonly under traditional breeding and unable to produce maximum performance and meat quality (CIVAS and FAO, 2006). Likewise, muscovy meat is less favorable in society due to its tough, dark, and musty meat.

Kim et al. (2008) found only 16% of white muscle fibers in duck breast meat but 100% of white muscle fibers in chicken breast meat. Besides, chicken breast has more protein than duck (22.0% vs 20.1%) but less fat than duck (1.8% vs 1.1%); accordingly, chicken pH is significantly lower than that of duck at 1-3 hour post mortem, but share common final pH at 24 hour. Qiao et al. (2001) reported that muscovy ducks, as well as other ducks, are mostly of red muscle fibers with minor white muscle fibers or 84% and 16%, respectively, which affects meat composition, biochemical and sensory characteristics.

Color still affects psychological response, economical value and consumer preferability toward food product. Meat color is determined by level and status of myoglobin pigment (Mancini and Hunt, 2005) and the appearing color depends on the order, age, sex (Wawro et al., 2004), muscle type, feed, pre-slaughter treatment and stress, slaughtering method and storage condition (Haraf et al., 2009). At 8 weeks old, myoglobin in red meat fowl is 0.4 mg/g, while in white meat fowl is 0.01 mg/g (Stadelman et al., 1988). Myoglobin content increases along with the age. Myoglobin and hemoglobin in meat can speed up fat oxidation that causes pungency and off-flavor because the increase of myoglobin is followed by Fe. Ion Fe is catalyst to speed up oxidation rate and Fe level is affected by species, sex, age, muscle, myoglobin and hemoglobin activity and Fe (in ferrous), because Fe is easily oxidized and causes dark meat color (Meluzzi et al., 2009; Apriyantono and Lingginganrum, 2001; Tang et al., 2000; Barciela et al., 2008; Min et al., 2010; Yoon et al., 2010).

Fat oxidation can be prevented or impeded by antioxidant whose usage to living fowl has to meet some requirements, among which are nontoxic, non-flavoring, non-coloring, effective in small amount, inexpensive, and readily available. Well-known antioxidant is vitamin C and vitamin E. Vitamin C has 2 hydroxyl groups are easily oxidized, so it will easily release electrons and hydrogen to donate to the free radicals so that free radicals are not reactive or unstable (Sediaoetama, 1987) and as a regenerator of vitamin E (Rukmiarsih et al., 2011). Vitamin E protects fatty acid from oxidation by trapping free radicals and is effective in cell membrane, while vitamin C is very efficient in trapping some compounds such as superoxide, hydrogen peroxide, hydroxyl radicals and peroxyl radicals. There is synergic interaction between vitamin E and C, in which the former is lipophilic and the latter is hydrophilic, also vitamin C can degenerate radical-formed vitamin E. (Lavoisier, 1998; Lamid, 1995; Winarsi, 2011). The objective this study was to determine the effect of vitamin E and C supplementation in feed on meet quality, thiobarbituric acid reactive substances (TBARS) and myoglobin level of muscovy duck.

MATERIALS AND METHODS

The materials used were 84 nine-week-old male muscovy duck weighing 850-1100 g, kept in 28 litter cage compartments each containing three heads. Muscovy ducks were reared for five weeks and at 14 weeks old, two ducks were taken from each compartment and slaughtered to take the meat and to analyze its physical quality, thiobarbituric acid reactive substances (TBARS) level and myoglobin level.

Ducks were given basal feed containing 21% protein, 3100 kcal/kg feed metabolic energy (30% corn, 7% soy bean meal, 38.20% poultry meat meal, 6.10% oil, 0.10 % L-lysine HCl, 0.30 % Dl-methionin, 0.20% topmix, 0.10% NaCl and 1% CaCO3), powdered vitamin E (d-α-tokoferalasetat) and vitamin C (L-ascorbic acid). Ducks were New Castle Diseases (NCD) vaccinated at first week. Drink water was supplied ad libitum and feed was given twice a day in the morning an afternoon.

Completely randomized design was applied, in which treatments were vitamin E and vitamin C supplementations to basal feed containing 21% protein and 3100 kcal/kg metabolic energy administered into seven groups, namely E0 : feed without Vit E and Vit C, E00 : feed plus 400 IU vitamin E, E200 : feed plus 600 IU vitamin E, C600: feed plus 400 mg/kg feed vitamin C, C300: feed plus 600 mg/kg feed vitamin C sebanyak, E200C200: feed plus 200 IU vitamin E and 200 mg /kg feed vitamin C, and E300C300: feedplus300 IU vitamin E and 300 mg /kg feed vitamin C. Each treatment was subject to four replications. The obtained data were then analyzed using...
RESULTS AND DISCUSSION

Meat Quality

The pH of muscovy duck meat in this research was 5.5-5.49 which was relatively similar to 5.7 ± 0.05 of male muscovy by Wawro et al. (2004). Table 1 shows that EₐC₀ was significantly different (P<0.01) from all other treatments; however, Eₓ₂₀₀, Eₓ₆₀₀, Cₓ₄₀₀, Cₓ₆₀₀, dan Eₓ₆₀₀Cₓ₃₀₀ were not different. This is because vitamin C and E function as antioxidant that prevents the forming of free radicals and increases oxidative stability of meat which affects muscle glycogen depletion rate. It was in line with Bou et al.(2006) that 150 mg/kg of α-tokoferol asetat supplementation in broiler ration for 32 days could increase chicken oxidative stability. El-habbak et al. (2011) reported that vitamin E and C have hydroxyl compound and are easy to donor electron and hydrogen to free radicals. Consequently, free radicals formation relatively more slowly and the cattle get healthier. In healthier cattle, muscle glycogen depletion rate is slower than that of stressed or sick animals. Accordingly, meat pH of muscovy EₓC₀ is lower than that of other treatments. It was in accordance with Choi et al. (2010) and Kim et al. (2009) that meat pH depletion rate was affected by antioxidant intake before slaughtering. Antioxidant effectively slow down the glycogen store depletion into lactic acid and prevent oxidative process by free radicals.

WHC of muscovy duck meat in this research ranged from 33.95 ± 0.09 to 36.52 ± 0.30. This values were higher than that of Utami et al. (2011) namely 26.75 -33.77% and 26.13%, respectively. Table 1 shows that feed without vitamin E and C supplementation (EₓC₀) produced different WHC (P>0.01) from all other treatments; Eₓ₂₀₀ was not different (P>0.05) from Cₓ₄₀₀, Cₓ₆₀₀ and Eₓ₂₀₀Cₓ₂₀₀. Also Eₓ₂₀₀Cₓ₃₀₀ was not different from Eₓ₁₀₀Cₓ₃₀₀. It demonstrated that muscovy WHC was affected by level of vitamin E and C administered. Vitamin E effectively maintains cell membrane integrity and meat juice loss that eventually affects WHC (Petraci and Cavani,2012), protects cell from endogenous free radicals (Rahman, 2003) and affects body fat (Rusmana et al., 2008). Vitamin C functions in carnitine synthesis that essentially serves in fatty acid transport from cytosol to mitochondria in fat biosynthesis, therefore WHC in vitamin C treatment is lower than that of vitamin E. The lower intramuscular fat level, the lower is water holding capacity by meat protein.
Table 1. Meat Quality of 14 Weeks old Muscovy Duck Given Vitamin C and E Supplementation

| Parameters | C_0 | C_400 | C_600 | E_400 | E_600 | E_200 | E_300 |

E_C_0: feed without Vit E and Vit C supplementation; E_400: feed plus 400 IU of vitamin E; E_600: feed plus 600 IU of vitamin E, C_400: feed plus 400 mg/kg feed of vitamin C; C_600: feed plus 600 mg/kg feed of vitamin C, E_200, C_200: feed plus 200 IU vitamin E and 200 mg/kg feed of vitamin C and E_300, C_300: feed plus 300 IU of vitamin E and 3 00 mg/kg feed of vitamin C. ^a-b^ shows highly significant (P<0.01)

Cooking loss of muscovy meat in this research ranged from 27.48 ± 0.74 to 36.60 ± 0.65%. These values were lower than that of Utami et al. (2011) but higher than that of Omojola (2007) on male muscovy namely 40.18% and 25.50%, respectively. E_C_0 was not different (P>0.05) from E_400, and E_600 was not different from C_400 and C_600. Furthermore, E_200 and C_200 was not different from C_400 and C_600 but E_200 and C_200 was different from E_300 (Table 1). Cooking loss process deals with water holding capacity as informed by Soeparno (2005) that the higher water holding capacity, the less juice loss during cooking, besides cooking loss is also affected by meat intramuscular fat. Muscle with high intramuscular fat tends to have high WHC and low cooking loss, because intramuscular fat resists or lessens meat juice extracted during cooking. Prawirokusumo (1990) stated that vitamin E is fat-soluble, effectively prevents fat oxidation that damages tissues; therefore, cooking loss when boiling meat can be reduced. Linder (1992) supported that at molecular level, vitamin C becomes reductive like vitamin E and active form. This characteristics is assumed to be able to defend cell stability from damage so that meat juice loss can be resisted.

Meat tenderness of 14 weeks old male muscovy that supplemented with vitamin C and E in feed have significantly effect (P<0.01). E_C_0 was different from (P<0.01) all treatments. E_400 was not different from (P>0.05) E_300 but E_400 was not different from (P>0.05) C_400, E_200 and E_300. Vitamin E is fat-soluble that maintains plasma membrane integrity (Khan et al., 2011) and eventually lowers meat juice loss so that drip depletes and WHC increases. This was in accordance with Li et al. (2009) that vitamin E supplementation in feed decrease the drip loss and increase tenderness but not significantly affected carcass production, while vitamin C is water-soluble antioxidant that significantly serves in forming intercellular collagen and fat metabolism. Collagen is a type of protein as the main component in connective tissue (Soeparno, 2005), so vitamin C efficacy in tenderness is still unstable. On the other hand, vitamin C synergized vitamin E will effectively increase meat tenderness.

**TBARS and Myoglobin Level**

The effect of vitamin E and C supplemements in feed resulted in 0.43 – 0.86 mg/100 g of TBARS level, or higher than that of muscovy fed with Pluchea indica scoring 0.302 - 0.359 mg/100 g (Rukmisih et al., 2009). Table 2 showed that feed supplemented with vitamin C and E significantly affected (P<0.01) myoglobin of 14 weeks old male muscovy. E_200 and C_200 was not different (P>0.05) from E_300 and C_300, also between E_C_0 and E_400 and between E_400 and C_400. Oxidation process gets faster when in alkali surrounding. Free oxygen in the air will oxidized double chained unsaturated fatty acid in food, and fatty acid oxidation would be followed by H₂O₂ formation that induced pungency. However, if antioxidant exists in feed, the active peroxide formed would react with antioxidant to prevent
free radicals formation and eventually slow down the formation of malonaldehyd (Lukman et al., 2007). Table 2 shows that antioxidant intake either vitamin C or E could impede oxidation and malonaldehyd formation in muscovy meat, those were observed from lower TBARS value compared to muscovy fed without vitamin C and E supplementation. Oxidative rate would differ due to the effect of characteristics and efficacy of antioxidant intake, meat fatty acid and unsaturated fatty acid. Fat level and unsaturated fatty acid of muscovy skinned meat in each treatment was relatively high, in that E₀C₀ was 6.72% and 42.64%, E₄₀₀ was 55.6% and 49.55%, E₆₀₀ was 7.23% and 37.64%, C₄₀₀ was 7.12% and 46.85%, C₆₀₀ was 6.89% and 43.41%, E₂₀₀C₂₀₀ was 7.07% and 32.86%, E₃₀₀C₃₀₀ was 7.11% and 45.01%. Furthermore, peroxide and TBARs scores according to Gheisari (2011) was positively correlated. Critical control point of meat tested by TBA RS was 15 mg/kg sample (Sanger, 2010).

Myoglobin is monomeric protein serves as oxygen storage site on skeletal muscle cell (striated muscle). This protein is composed of at least 154 amino acid chains and one heme compound (porphyrin chain with one Fe atom). Myoglobin level of breast meat of muscovy ranged from 4.98 ± 1.61 to 9.07 ± 0.57 mg/g. Myoglobin level in this research was higher than that of Gheisari (2011) stated that chicken myoglobin was 0.31±0.07 mg/g. Feed supplemented with vitamin C and E significantly affected (P<0.01) myoglobin of 14 weeks old male muscovy. E₀C₀ was not different from E₄₀₀C₄₀₀ and E₆₀₀C₆₀₀, E₄₀₀C₄₀₀ and E₃₀₀C₃₀₀. E₂₀₀C₂₀₀ was different from E₀C₀ and E₄₀₀. E₂₀₀C₂₀₀ was different from E₀C₀ (Table 2 and Figure 1). The lowest muscovy myoglobin level was due to feed supplemented with vitamin C, because vitamin C can increase triglyceride and affect muscle glycogen stores. Glycolysis rate became slower causing denaturation of muscle.

Table 2. Myoglobin and TBARS Level of 14 Week old Muscovy Duck Meat Given Vitamin C and E Supplementation

| Parameters | E₀C₀ | E₄₀₀ | E₆₀₀ | C₄₀₀ | C₆₀₀ | E₂₀₀C₂₀₀ | E₃₀₀C₃₀₀ |
|------------|------|------|------|------|------|----------|----------|
| TBARS (mg MA/100 g) | 0.86±0.14<sup>c</sup> | 0.82±0.01<sup>c</sup> | 0.52±0.00<sup>ab</sup> | 0.52±0.01<sup>ab</sup> | 0.62±0.01<sup>b</sup> | 0.44±0.01<sup>a</sup> | 0.43±0.01<sup>a</sup> |

E₀C₀: feed without Vit E and Vit C supplementation; E₄₀₀: feed plus 400 IU of vitamin E; E₆₀₀: feed plus 600 IU of vitamin E, C₄₀₀: feed plus 400 mg/kg feed of vitamin C; C₆₀₀: feed plus 600 mg/kg feed of vitamin C, E₂₀₀C₂₀₀: feed plus 200 IU vitamin E and 200 mg /kg feed of vitamin C and E₃₀₀C₃₀₀: feed plus 300 IU of vitamin E and 3 00 mg /kg feed of vitamin C. <sup>abcd</sup> shows highly significant (P<0.01)

Figures 1. Meat Color of Each Treatment
protein including myoglobin. Nelson and Cox (2008) stated that myoglobin has high oxygen holding capacity, making it easily oxidized, and turning into bright red (Mb) oxidation. Fletcher (2003) and Allen (2009) stated that myoglobin consists of heme and globin compound. Heme compound is hydrophobic consisting of one Fe ion with four nitrogen porphyrin rings. The sixth Fe bond is easily oxidized that turns meat color into dark.

Zouari et al. (2010) mentioned that vitamin E prevents lipid oxidation, is effective to stabilize meat color, but excessive amount will lose the red color in meat because vitamin E can induce metmyoglobin very fast. Besides myoglobin, meat color is also affected by the extracted hemoglobin when slaughtered. Hemoglobin level of each treatment at slaughtering showed that E$_{0}$C$_{0}$ was 11.28 ± 2.88 g/dl; E$_{400}$ was 14.75 ± 3.76 g/dl; E$_{600}$ was 12.55 ± 3.76 g/dl; C$_{400}$ was 16.35 ± 2.06 g/dl; C$_{600}$ was 11.70 ± 1.57 g/dl; E$_{500}$C$_{200}$ was 13.40 ± 2.51 g/dl and E$_{500}$C$_{300}$ was 13.18 ± 2.01 g/dl.

CONCLUSION

Supplementation of 300 IU vitamin E and 300 mg vitamin C into feed with 21% protein and 3100 kcal/mg metabolic energy can recover WHC, cooking loss, flavor and meat color of muscovy duck, however, the highest meat tenderness was resulted from 400 IU vitamin E supplementation.
