The twisting representation of the
$L$-function of a curve

Francesc Fité and Joan-C. Lario

December 5, 2012

Abstract

Let $C$ be a smooth projective curve defined over a number field and let $C'$ be a twist of $C$. In this article we relate the $\ell$-adic representations attached to the $\ell$-adic Tate modules of the Jacobians of $C$ and $C'$ through an Artin representation. This representation induces global relations between the local factors of the respective Hasse-Weil $L$-functions. We make these relations explicit in a particularly illustrating situation. For every $\mathbb{Q}$-isomorphism class of genus 2 curves defined over $\mathbb{Q}$ with $\text{Aut}(C) \simeq D_8$ or $D_{12}$, except for a finite number, we choose a representative curve $C/\mathbb{Q}$ such that, for every isomorphism $\phi: C' \to C$ satisfying some mild condition, we are able to determine either the local factor $L_p(C'/\mathbb{Q}, T)$ or the product $L_p(C'/\mathbb{Q}, T) \cdot L_p(C'/\mathbb{Q}, -T)$ from the local factor $L_p(C/\mathbb{Q}, T)$.

1 Introduction

Let $C$ and $C'$ be smooth projective curves of genus $g \geq 1$ defined over a number field $k$ that become isomorphic over an algebraic closure of $k$ (that is, they are twisted of each other). The aim of this article is to relate the $\ell$-adic representations attached to the $\mathbb{Q}_\ell$-vector spaces $V_\ell(C)$ and $V_\ell(C')$. Here, for a prime $\ell$, $V_\ell(C)$ stands for $\mathbb{Q}_\ell \otimes T_\ell(C)$, where $T_\ell(C)$ denotes the $\ell$-adic Tate module of the Jacobian variety $J(C)$ attached to $C$ (and analogously for $C'$).

The case of quadratic twists of elliptic curves is well known. If $E$ and $E'$ are elliptic curves defined over $k$ that become isomorphic over a quadratic extension $L/k$, then there exists a character $\chi$ of $\text{Gal}(L/k)$ such that

$$V_\ell(E') \cong \chi \otimes V_\ell(E).$$

(1.1)

This translates into a relation of local factors of the corresponding Hasse-Weil $L$-functions. Indeed, one has that for every prime $\mathfrak{p}$ of $k$ unramified in $L$

$$L_p(E'/k, T) = L_p(E/k, \chi(\text{Frob}_\mathfrak{p})T).$$

(1.2)

So from now on, we will assume that the genus of $C$ (and $C'$) is $g \geq 2$, and we will focus on obtaining a generalization of relation (1.1).

Let us fix some notation. Hereafter, $\overline{\mathbb{Q}}$ denotes a fixed algebraic closure of $\mathbb{Q}$ that is assumed to contain $k$ and all of its algebraic extensions. For any algebraic extension $F/k$, we will write $G_F := \text{Gal}(\overline{\mathbb{Q}}/F)$. For abelian varieties $A$ and $B$ defined over $k$, denote by $\text{Hom}_F(A, B)$ the $\mathbb{Z}$-module of homomorphisms
from $A$ to $B$ defined over $F$, and by $\text{End}_F(A)$ the ring of endomorphisms of $A$ defined over $F$. Write $\text{Hom}_F^0(A, B)$ for the $\mathbb{Q}$-vector space $\mathbb{Q} \otimes \text{Hom}_F(A, B)$, and $\text{End}_F^0(A)$ for the algebra $\mathbb{Q} \otimes \text{End}_F(A)$. We write $A \sim_F B$ to denote that $A$ and $B$ are isogenous over $F$.

### 1.1 Relating $\ell$-adic representations of twisted curves

Let $\text{Aut}(C)$ be the group of automorphisms defined over $\mathbb{Q}$ of $C$, and let $\text{Isom}(C', C)$ be the set of all isomorphisms from $C'$ to $C$. Throughout the paper, $L/k$ (resp., $K/k$) will denote the minimal extension of $k$ where all the elements in $\text{Isom}(C', C)$ (resp., in $\text{Aut}(C)$) are defined. A theorem of Hurwitz asserts that $\text{Aut}(C)$ has order less or equal than $84(g-1)$. Since the isomorphism $\phi$ induces a bijection between $\text{Aut}(C)$ and $\text{Isom}(C', C)$, in particular, we have that these two sets are finite. Thus, the extensions $K/k$ and $L/k$ are finite. Since the curves $C$ and $C'$ are defined over $k$, the extensions $K/k$ and $L/k$ are Galois extensions. Clearly, $K/k$ is a subextension of $L/k$. We can now state the principal result of Section 2.

**Theorem 1.1.** The representation

$$\theta_C : G_C := \text{Aut}(C) \rtimes_\lambda_C \text{Gal}(K/k) \to \text{Aut}(\text{End}_K^0(J(C))),$$

defined by equation (2.2) and called the twisting representation of $C$, satisfies that, for every $\theta_C$-twist $\phi : C' \to C$, there is an inclusion of $\mathbb{Q}_\ell[G_k]$-modules

$$V_\ell(C') \subseteq (\theta_C \circ \lambda_\phi) \otimes V_\ell(C). \quad (1.3)$$

Here $\lambda_\phi : \text{Gal}(L/k) \to G_C$ stands for the monomorphism defined by equation (2.1).

This result encompasses Remark 2.1, Proposition 2.3 and Theorem 2.1, and we refer to the remaining results of Section 2 for proofs of the well-definition of the objects involved in the statement. Requiring a twist $C'$ of $C$ to be a $\theta_C$-twist is a mild condition that we precise in Definition 2.1. In Proposition 2.4, we show that (1.3) indeed generalizes (1.1).

### 1.2 Applications

In the particular cases that we will look at, one can in fact compute the whole decomposition of $(\theta_C \circ \lambda_\phi) \otimes V_\ell(C)$. This leads to a relation between local factors of $C$ and local factors of $C'$ of the style of (1.2), that is, a relation written in terms of an Artin representation. Such kind of global relations have been proved to be most useful when one is interested in the study of the behaviour of the local factor at a varying prime (e.g. generalized Sato-Tate distributions; see Section 4 of [Fit10] and especially [FS12]).

The essential feature of the cases considered in which one can perform the computation of the decomposition of $(\theta_C \circ \lambda_\phi) \otimes V_\ell(C)$ is the splitting of the Jacobian $J(C)$ over $K$ as the power of an elliptic curve $E/K$ (what we call the completely splitted Jacobian case). In this article we restrict to the case in which $E$ does not have complex multiplication (CM), and we refer to [FS12] for a treatment of the case in which $E$ has CM.
After the considerations of general type for the completely split Jacobian case of Section 3, we restrict our attention in Section 4 to the situation in which \( C \) is a genus 2 curve defined over \( \mathbb{Q} \) with \( \text{Aut}(C) \simeq D_8 \) (resp. \( D_{12} \)). Recall that every such a curve is \( \mathbb{Q} \)-isomorphic to a curve \( C_u \) in the family of \((\mathbb{A}_3)\) (resp. in the family of \((\mathbb{B}_3)\)) for some \( u \) in \( \mathbb{Q}^* \setminus \{1/4, 9/100\} \) (resp. in \( \mathbb{Q}^* \setminus \{1/4, -1/50\} \)). We then prove the following result.

**Theorem 1.2.** Let \( \phi : C' \to C \) be a twist of \( C = C_u \) with \( \text{Aut}(C) \simeq D_8 \) (resp. \( \text{Aut}(C) \simeq D_{12} \)). Assume that \( u \) does not belong to the finite list \([(4.1)]\) (resp. \([(4.2)]\)). If \( V_\ell(C') \) is a simple \( \mathbb{Q}_\ell[G_K] \)-module, then for every prime \( p \) unramified in \( L/\mathbb{Q} \), we have

\[
L_p(C/\mathbb{Q}, \theta_C \circ \lambda_\phi, T) = \begin{cases} 
L_p(C'/\mathbb{Q}, T)^4 & \text{if } f = 1 \\
L_p(C'/\mathbb{Q}, T)^{2}L_p(C'/\mathbb{Q}, -T)^2 & \text{if } f = 2,
\end{cases}
\]

where \( f \) denotes the residue class degree of \( p \) in \( K \).

In the statement of the theorem, \( L_p(C/\mathbb{Q}, \theta_C \circ \lambda_\phi, T) \) stands for the Rankin-Selberg polynomial whose roots are all the products of roots of \( L_p(C/\mathbb{Q}, T) \) and roots of \( \det(1 - \theta_C \circ \lambda_\phi(\text{Frob}_p)T) \).

## 2 The twisting representation \( \theta_C \)

For any twist \( C' \) of a smooth projective curve \( C \) defined over \( k \) of genus \( g \geq 2 \), let \( K/k \) and \( L/k \) be as in the Introduction. We will write the natural action of the group \( \text{Gal}(L/k) \) on \( \text{Aut}(C) \), \( \text{Isom}(C', C) \), \( \text{End}_{\mathbb{Q}}^0(J(C)) \), and \( \text{Hom}_{\mathbb{Q}}^0(J(C), J(C')) \) using left exponentiation and we will often avoid writing \( \circ \) for the composition of maps. Then, we have the following monomorphism of groups

\[
\lambda_C : \text{Gal}(K/k) \to \text{Aut}(\text{Aut}(C)), \quad \lambda_C(\sigma) = \sigma \alpha.
\]

Indeed, the minimality of \( K \) guarantees that if \( \sigma \in \text{Gal}(K/k) \) is such that \( \alpha = \sigma \alpha \) for every \( \alpha \in \text{Aut}(C) \), then \( \sigma \) is trivial. We define the twisting group of \( C \) as

\[
G_C := \text{Aut}(C) \rtimes_{\lambda_C} \text{Gal}(K/k),
\]

where \( \rtimes_{\lambda_C} \) denotes the semidirect product through the morphism \( \lambda_C \). We now proceed to somehow justify the name of \( G_C \). First, we fix some notation. Suppose that \( F'/k \) is a Galois extension and that \( F/k \) is a Galois subextension of \( F'/k \). Then, let \( \pi_{F'/F} : \text{Gal}(F'/k) \to \text{Gal}(F/k) \) stand for the canonical projection. For every isomorphism \( \phi : C' \to C \), define the map

\[
\lambda_\phi : \text{Gal}(L/k) \to G_C, \quad \lambda_\phi(\sigma) = (\phi(\sigma \phi)^{-1}, \pi_{L/K}(\sigma)).
\]

**Lemma 2.1.** The map \( \lambda_\phi \) is a monomorphism of groups.

**Proof.** Let \( \sigma \) and \( \tau \) belong to \( \text{Gal}(L/k) \). Then, we have

\[
\lambda_\phi(\sigma \tau) = (\phi(\sigma \tau \phi)^{-1}, \pi_{L/K}(\sigma \tau))
\]

\[
= (\phi(\sigma \phi)^{-1} \circ \sigma(\phi(\tau \phi)^{-1}), \pi_{L/K}(\sigma))
\]

\[
= (\phi(\sigma \phi)^{-1} \lambda_C(\pi_{L/K}(\sigma))(\phi(\tau \phi)^{-1}), \pi_{L/K}(\sigma) \circ \pi_{L/K}(\tau))
\]

\[
= (\phi(\sigma \phi)^{-1}, \pi_{L/K}(\sigma))(\phi(\tau \phi)^{-1}, \pi_{L/K}(\tau)) = \lambda_\phi(\sigma) \circ \lambda_\phi(\tau).
\]
Let $\sigma \in \text{Gal}(L/k)$ be such that $\phi(\sigma)^{-1} = \text{id}$ and $\pi_{L/K}(\sigma)$ is trivial, i.e., $\phi = \sigma \phi$ and $\sigma \in \text{Gal}(L/K)$. Let $\psi$ be any element of $\text{Isom}(C', C)$. Since $\psi \phi^{-1}$ is an element of $\text{Aut}(C)$, it is fixed by $\sigma$. Then, one has
\[\sigma \psi = \sigma (\psi \phi^{-1} \phi) = \sigma (\psi \phi^{-1}) = \psi \phi^{-1} \phi = \psi.\]
The minimality of $L$ guarantees now that $\sigma$ is trivial.

**Proposition 2.1.** A one-to-one correspondence between the elements of the following sets:

i) The set $\text{Twist}(C/k)$ of twists of $C$ up to $k$-isomorphism;

ii) The set of monomorphisms $\lambda: \text{Gal}(F/k) \to G_C$ of the form $\lambda = \xi \lambda_1$, $\pi_{F/K}$, with $\xi$ a map from $\text{Gal}(F/k)$ to $\text{Aut}(C)$, where we identify $\lambda_1: \text{Gal}(F_1/k) \to G_C$ and $\lambda_2: \text{Gal}(F_2/k) \to G_C$

if there exists $\alpha \in \text{Aut}(C)$ such that, for every $\sigma \in \text{Gal}(F_1 F_2/k)$, one has
\[\lambda_1 \circ \pi_{F_1 F_2/F_1}(\sigma)(\alpha, 1) = (\alpha, 1) \lambda_2 \circ \pi_{F_1 F_2/F_1}(\sigma);\]
is given by associating to a twist $C'$ of $C$ the class of the monomorphism $\lambda_\phi$, where $\phi$ is any isomorphism from $C$ to $C'$.

**Proof.** There is a well-known bijection between the elements of $\text{Twist}(C/k)$ and the elements of the cohomology set $H^1(G_k, \text{Aut}(C))$, given by associating to a twist $C'$ of $C$ the class of the cocycle $\xi(\sigma) = \phi(\sigma \phi)^{-1}$ (see [Sli86], chapter X). Now, associate to the cocycle $\xi$, the morphism $\lambda: G_k \to G_C$, defined by $\lambda = \xi \times \lambda_1 \pi_{F/K}$. Observe that, for $\sigma, \tau$ in $G_k$, one has that $\lambda(\sigma \tau) = \lambda(\sigma) \lambda(\tau)$ if and only if $\xi(\sigma \tau) = \xi(\sigma) \circ \sigma \xi(\tau)$. Let $G_F$ denote the kernel of $\lambda$ and let $\lambda: \text{Gal}(F/k) \to G_C$ satisfy $\lambda = \lambda \circ \pi_{F/F}$. Then $\lambda$ is injective. Moreover, the cocycles $\xi_1$ and $\xi_2$ are cohomologous if and only if there exists $\alpha$ in $\text{Aut}(C)$ such that for all $\sigma$ in $G_k$ it holds $\xi_1(\sigma) \circ \sigma \alpha = \alpha \circ \xi_2(\sigma)$, which is equivalent to $\lambda_1(\sigma)(\alpha, 1) = (\alpha, 1) \lambda_2(\sigma)$. Finally, this amounts to ask that $\lambda_1 \circ \pi_{F_1 F_2/F_1}(\sigma)(\alpha, 1) = (\alpha, 1) \lambda_2 \circ \pi_{F_1 F_2/F_1}(\sigma)$ for every $\sigma \in \text{Gal}(F_1 F_2/k)$.

**Proposition 2.2.** The monomorphism $\lambda_\phi$ is an isomorphism if and only if the action of $\text{Gal}(L/K)$ on $\text{Isom}(C', C)$ has a single orbit.

**Proof.** One has that $\lambda_\phi$ is exhaustive if and only if $|\text{Aut}(C)| = |\text{Gal}(L/K)|$. This is equivalent to the fact that the injective morphism
\[\lambda: \text{Gal}(L/K) \to \text{Aut}(C), \quad \lambda(\sigma) = \phi(\sigma \phi)^{-1}\]
is an isomorphism. This happens if and only if for every $\alpha \in \text{Aut}(C)$ there exists $\sigma \in \text{Gal}(L/K)$ such that $\alpha \phi = \sigma \phi$, that is, if and only if for every $\psi \in \text{Isom}(C', C)$, there exists $\sigma \in \text{Gal}(L/K)$ such that $\psi = \sigma \phi$.

**Remark 2.1.** For any twist $C'$ of $C$, the abelian varieties $J(C)$ and $J(C')$ are defined over $k$ and are isogenous over $L$. Let $F/k$ be a subextension of $L/k$. Denote by $\theta(C, C': L/F)$ the representation afforded by the $\mathbb{Q}[\text{Gal}(L/F)]$-module $\text{Hom}_L(J(C), J(C'))$. We will write $\theta(C, C'): L/F \in \text{Isom}(C', C)$ as $\mathbb{Q}[\text{Gal}(L/F)]$-modules.
Every isomorphism $\phi$ from $C'$ to $C$ induces an isomorphism from $J(C')$ to $J(C)$, that we will also call $\phi$. Consider the map $$\theta_\phi: \text{Gal}(L/k) \to \text{Aut}_\mathbb{Q}(\text{End}^0_L(J(C)))$$, $$\theta_\phi(\sigma)(\psi) = (\sigma \circ \phi)^{-1} \circ \sigma \psi,$$ where $\sigma$ is in $\text{Gal}(L/k)$ and $\psi$ in $\text{End}^0_L(J(C))$.

**Proposition 2.3.** For every isomorphism $\phi: C' \to C$, the map $\theta_\phi$ is a rational representation of $\text{Gal}(L/k)$ isomorphic to $\theta(C,C')$.

**Proof.** It is indeed a representation. For $\sigma$ and $\tau$ in $\text{Gal}(L/k)$, one has $$\theta_\phi(\sigma \tau)(\psi) = (\sigma \tau \circ \phi)^{-1} \circ (\sigma \tau \circ \psi) = (\sigma \circ (\sigma \tau \phi)^{-1} \circ \tau \circ \psi).$$

The map $\tilde{\phi}: \text{Hom}_L^0(J(C),J(C')) \to \text{End}_L^0(J(C))$, defined by $\tilde{\phi}(\varphi) = \phi \circ \varphi$ for $\varphi \in \text{Hom}_L^0(J(C),J(C'))$ is an isomorphism of $\mathbb{Q}$-vector spaces. Now, one deduces that $\theta(C,C')$ and $\theta_\phi$ are isomorphic from the fact that, for every $\sigma$ in $\text{Gal}(L/k)$, the following diagram is commutative

\[
\begin{array}{ccc}
\text{Hom}_L^0(J(C),J(C')) & \xrightarrow{\theta(C,C')(\sigma)} & \text{Hom}_L^0(J(C),J(C')) \\
\downarrow \tilde{\phi} & & \downarrow \tilde{\phi} \\
\text{End}_L^0(J(C)) & \xrightarrow{\theta_\phi(\sigma)} & \text{End}_L^0(J(C)).
\end{array}
\]

Denote also by $\alpha$ the induced endomorphism in $J(C)$ by an automorphism $\alpha$ in $\text{Aut}(C)$. We define the twisting representation of the $L$-function of $C$ as the map $$\theta_C: G_C \to \text{Aut}_\mathbb{Q}(\text{End}^0_K(J(C))), \quad \theta_C((\alpha,\sigma))(\psi) = \alpha \circ \sigma \psi, \quad (2.2)$$ where $\sigma$ in $\text{Gal}(K/k)$ and $\psi$ in $\text{End}^0_K(J(C))$.

**Definition 2.1.** We will say that a twist $C'$ of $C$ is a $\theta_C$-twist of $C$ if $L$ is such that $\text{End}^0_K(J(C')) = \text{End}^0_L(J(C))$.

**Theorem 2.1.** The map $\theta_C$ is a faithful representation of $G_C$. Moreover, for every $\theta_C$-twist $C'$ of $C$ and every isomorphism $\phi: C' \to C$, one has $\theta_C \circ \lambda_\phi = \theta_\phi$, that is, the following diagram is commutative

\[
\begin{array}{ccc}
\text{Gal}(L/k) & \xrightarrow{\lambda_\phi} & G_C \\
\downarrow \theta_\phi & & \downarrow \theta_C \\
\text{Aut}_\mathbb{Q}(\text{End}^0_K(J(C))) & \xrightarrow{\theta_C} & \text{End}^0_K(J(C)).
\end{array}
\]
Proof. For $\psi_1, \psi_2$ in $\text{Aut}(C)$ and $\sigma_1, \sigma_2$ in $\text{Gal}(K/k)$, one has

$$\theta_C((\alpha_1, \sigma_1) (\alpha_2, \sigma_2)) (\psi) = \theta_C((\alpha_1 \circ \sigma_1, \alpha_2, \sigma_1 \sigma_2)) (\psi)$$

$$= \alpha_1 \circ \sigma_1 \circ \alpha_2 \circ \sigma_1 \circ \sigma_2 \psi$$

$$= \alpha_1 \circ \sigma_1 (\alpha_2 \circ \sigma_2 \psi)$$

$$= (\theta_C((\alpha_1, \sigma_1)) \circ \theta_C((\alpha_2, \sigma_2))) (\psi).$$

Let $\alpha$ in $\text{Aut}(C)$ and $\sigma$ in $\text{Gal}(K/k)$ be such that $\theta_C(\alpha, \sigma) (\psi) = \psi$ for every $\psi$ in $\text{End}_K^0(J(C))$. In particular, for $\psi = \alpha$, one obtains that $\sigma \alpha = \text{id}$, which implies $\alpha = \text{id}$. Then $\psi = \sigma \psi$ for all $\psi$ in $\text{End}_K^0(J(C))$ and the minimality of $K$ implies that $\sigma$ is trivial. Finally, it holds

$$(\theta_C \circ \lambda_\phi)(\sigma)(\psi) = \theta_C(\phi(\sigma \phi)^{-1}, \pi_{L/K}(\sigma))(\psi) = \phi(\sigma \phi)^{-1} \circ \sigma \psi = \theta_\phi(\sigma)(\psi),$$

for $\sigma$ in $\text{Gal}(L/k)$ and $\psi$ in $\text{End}_L^0(J(C))$. \(\Box\)

As a corollary of the previous results one obtains the desired inclusion

$$V_\ell(C') \subseteq (\theta_C \circ \lambda_\phi) \otimes V_\ell(C) \quad (2.3)$$

for every $\theta_C$-twist $C'$ of $C$. This inclusion is a generalization of the identity \((1.1)\).

**Proposition 2.4.** If $C'$ is a nontrivial twist of $C$ such that $\text{End}_L^0(J(C)) \simeq \mathbb{Q}$, then the extension $L/k$ is quadratic, the representation $\theta_C \circ \lambda_\phi$ is the quadratic character of $\text{Gal}(L/k)$, and one has $V_\ell(C') \simeq (\theta_C \circ \lambda_\phi) \otimes V_\ell(C)$.

*Proof.* By the inclusion \((2.3)\), it is enough to prove that $L/k$ is quadratic and that $\theta(C, C')$ is the quadratic character of $L/k$. Since $\text{Aut}(C)$ injects in $\text{End}_L^0(J(C)) = \text{End}_K^0(J(C)) \simeq \mathbb{Q}$, we have that $\text{Aut}(C)$ injects in $C_2$ and that $K = k$. Since $C'$ is nontrivial, then $\text{Aut}(C)$ is nontrivial and, by Lemma \(2.1\), we deduce that $L/k$ is a quadratic extension. Since the 1-dimensional representation $\theta(C, C')$ is faithful, it corresponds to the quadratic character of $\text{Gal}(L/k)$. \(\Box\)

## 3 The completely splitted Jacobian case

In this section we explore the twisting representation $\theta_C$ when the Jacobian $J(C)$ splits over $K$ as the power $E^g$ of an elliptic curve $E$ defined over $K$ without complex multiplication (CM). Note that in this case $\dim \theta_C = g^2$. We will use the notation $H_C = \text{Aut}(C)$ when we see $\text{Aut}(C)$ as a subgroup of the twisting group $G_C$. For future use, we will be interested in the following cases:

(I) $[K : k] = g^2$, the elliptic curve $E$ does not have CM, and $\theta_C$ is absolutely irreducible.

(II) $[K : k] = g^2/2$, the elliptic curve $E$ does not have CM, and $\theta_C \simeq \theta_1 \oplus \theta_2$ for $\theta_1$ and $\theta_2$ absolutely irreducible non-isomorphic representations such that $\text{Res}_{H_C}^G \theta_1 = \text{Res}_{H_C}^G \theta_2$. 

Lemma 3.1. Suppose that \( J(C) \sim_K E^9 \), for \( E \) an elliptic curve defined over \( K \) without CM. One has:

\[
\Res_{H_C}^G \theta_C \simeq g \cdot \varrho,
\]

where \( \varrho \) is a rational representation of \( H_C \) of dimension \( g \).

Proof. Consider the isomorphism

\[
\Phi: \End_K^0(J(C)) \simeq \End_K^0(E^9) \rightarrow \bigoplus_{i=1}^g \Hom_K^0(E, E^9),
\]

defined by \( \Phi(\varphi) = (\varphi \circ \iota_1, \ldots, \varphi \circ \iota_g) \), where \( \iota_i: E \rightarrow E^9 \) is the inclusion of \( E \) to the \( i \)-th component of \( E^9 \). The action of \( H_C = \text{Aut}(C) \), which is by right composition, clearly restricts to each \( \Hom_K^0(E, E^9) \). The rational representation \( \varrho \) afforded by \( \Hom_K^0(E, E^9) \) satisfies \( \Res_{H_C}^G \theta_C \simeq g \cdot \varrho \), and has dimension \( g \) provided that \( E \) has no CM.

Proposition 3.1. Suppose that \( J(C) \sim_K E^9 \), for \( E \) an elliptic curve defined over \( K \). Suppose we are either in case (I) or (II). Let \( \varrho \) be as in Lemma 3.1.

Then, one has

\[
\Ind_{H_C}^G \varrho \simeq \left[ \frac{K}{k} \right] \cdot \theta_C.
\]

Proof. Let \((\cdot, \cdot)_{G_C}\) and \((\cdot, \cdot)_{H_C}\) denote the scalar products on complex-valued functions on \( G_C \) and \( H_C \), respectively. For the case (I), by Frobenius reciprocity, the multiplicity of \( \theta_C \) in \( \Ind_{H_C}^G \varrho \) is

\[
(\Tr \Ind_{H_C}^G \varrho, \Tr \theta_C)_{G_C} = (\Tr \varrho, \Tr \Res_{H_C}^G \theta_C)_{H_C} = g \cdot (\Tr \varrho, \Tr \theta_C)_{H_C} \geq g.
\]

Since \([K : k] = g^2\), the dimensions of \( \Ind_{H_C}^G \varrho \) and \( g \cdot \theta_C \) equal \( g^3 \), and the result follows.

For the case (II), observe that \( \Res_{H_C}^G \theta_1 = \Res_{H_C}^G \theta_2 \) implies that \( \Res_{H_C}^G \theta_1 = g/2 \cdot \varrho \). Then, the multiplicity of \( \theta_1 \) in \( \Ind_{H_C}^G \varrho \) is

\[
(\Tr \Ind_{H_C}^G \varrho, \Tr \theta_1)_{G_C} = (\Tr \varrho, \Tr \Res_{H_C}^G \theta_1)_{H_C} = \frac{g}{2} \cdot (\Tr \varrho, \Tr \theta_C)_{H_C} \geq \frac{g}{2},
\]

from which one sees that \( g/2 \cdot \theta_1 \) is a subrepresentation of \( \Ind_{H_C}^G \varrho \). Analogously, one proves that \( g/2 \cdot \theta_2 \) is a subrepresentation of \( \Ind_{H_C}^G \varrho \). Therefore, \( g/2 \cdot \theta_C \) is a subrepresentation of \( \Ind_{H_C}^G \varrho \) and, since they both have dimension equal to \( g^3/2 \), they are isomorphic.

Corollary 3.1. Suppose that \( J(C) \sim_K E^9 \), for \( E \) an elliptic curve defined over \( K \). Suppose we are either in case (I) or (II). Then, one has

\[
\Ind_{H_C}^G \Res_{H_C}^G \theta_C \simeq [K : k] \cdot \theta_C.
\]

In what follows we will be particularly interested in the structure of \( V_1(C) \) as a \( \mathbb{Q}[G_K] \)-module. First, we settle the following notation. For an isomorphism \( \phi: C' \rightarrow C \), denote by

\[
\Res \lambda_\phi: \Gal(L/K) \rightarrow \Aut(C)
\]

the restriction of the morphism \( \lambda_\phi \) to the subgroup \( \Gal(L/K) \). Observe that

\[
\Res_{H_C}^G \theta_C \circ \Res \lambda_\phi \simeq \theta(C, C'; L/K).
\]
Theorem 3.1. Suppose that $J(C) \sim_K E^3$, for $E$ an elliptic curve defined over $K$. Let $C'$ be a $\theta_C$-twist of $C$. Suppose that $V_\ell(C')$ is a simple $\mathbb{Q}_\ell[G_K]$-module. Then, one has:

$$\theta(C, C') \otimes V_\ell(C) \simeq \begin{cases} 
\mathbb{Q}[\text{Gal}(K/k)] \otimes V_\ell(C') & \text{if (I)}, \\
2 \cdot \mathbb{Q}[\text{Gal}(K/k)] \otimes V_\ell(C') & \text{if (II)}. 
\end{cases}$$

Proof. For the case (I), recall that by Theorem 3.1 in [Fit10] there is an inclusion of $\mathbb{Q}_\ell[G_K]$-modules

$$V_\ell(C') \subseteq \theta(C, C'; L/K) \otimes V_\ell(C) \simeq (\text{Res}_{H_C}^G \theta_C \circ \text{Res} \lambda_\phi) \otimes V_\ell(C) \simeq g^2 \cdot (\varphi \circ \text{Res} \lambda_\phi) \otimes V_\ell(E).$$

Since $V_\ell(C')$ is a simple $\mathbb{Q}_\ell[G_K]$-module, we obtain that

$$V_\ell(C') \simeq (\varphi \circ \text{Res} \lambda_\phi) \otimes V_\ell(E). \quad (3.1)$$

Now, tensoring by $g \cdot \mathbb{Q}[\text{Gal}(K/k)]$ on both sides of the previous isomorphism we get

$$g \cdot \mathbb{Q}[\text{Gal}(K/k)] \otimes V_\ell(C') \simeq g \cdot \text{Ind}_{K}^G (\varphi \circ \text{Res} \lambda_\phi) \otimes V_\ell(E) \simeq \text{Ind}_{K}^G (\varphi \circ \text{Res} \lambda_\phi) \otimes V_\ell(C) \simeq (\text{Ind}_{H_C}^G \varphi \circ \lambda_\phi) \otimes V_\ell(C) \simeq g \cdot (\theta \circ \lambda_\phi) \otimes V_\ell(C) \simeq g \cdot \theta \otimes V_\ell(C) \simeq g \cdot \theta(C, C') \otimes V_\ell(C),$$

where we have used that $\text{Ind}_{H_C}^G \varphi = g \cdot \theta_C$, as seen in Proposition 3.1. For the case (II), everything is analogous to case (I) until equation (3.1). Then, tensoring by $2g \cdot \mathbb{Q}[\text{Gal}(K/k)]$, we get

$$2g \cdot \mathbb{Q}[\text{Gal}(K/k)] \otimes V_\ell(C') \simeq 2g \cdot \text{Ind}_{K}^G (\varphi \circ \text{Res} \lambda_\phi) \otimes V_\ell(E) \simeq 2 \cdot \text{Ind}_{K}^G (\varphi \circ \text{Res} \lambda_\phi) \otimes V_\ell(C) \simeq 2 \cdot (\text{Ind}_{H_C}^G \varphi \circ \lambda_\phi) \otimes V_\ell(C) \simeq g \cdot (\theta \circ \lambda_\phi) \otimes V_\ell(C) \simeq g \cdot \theta(C, C') \otimes V_\ell(C).$$

\[\square\]

Corollary 3.2. Assume the same hypothesis of Theorem 3.1 and that one of the cases (I) or (II) holds. Let $p$ a prime of good reduction for both $C$ and $C'$ unramified in $L/k$. Write $a_p = \text{Tr} \varphi_C(\text{Frob}_p)$ and $a'_p = \text{Tr} \varphi_C'(\text{Frob}_p)$. Then:
i) If $\text{Frob}_p \in G_K$, one has
$$\text{sgn}(a_p \cdot \text{Tr}(\theta(C, C')(\text{Frob}_p))) = \text{sgn}(a'_p).$$

ii) If $\text{Frob}_p \not\in G_K$, one has
$$\text{Tr}(\theta(C, C')(\text{Frob}_p)) = 0.$$

**Proof.** Theorem 3.1 implies
$$\text{Tr}(\theta(C, C')(\text{Frob}_p)) \cdot a_p = a'_p \cdot \text{Tr}(\mathbb{Q}[\text{Gal}(K/k)](\text{Frob}_p)).$$
Part i) follows from the fact that if $\text{Frob}_p \in G_K$, then
$$\text{Tr}(\mathbb{Q}[\text{Gal}(K/k)](\text{Frob}_p)) = |\text{Gal}(K/k)|.$$

For part ii), suppose that $\text{Frob}_p \not\in G_K$. Corollary 3.1 implies that $\text{Tr}(\theta(C, \sigma)) = 0$ for any $\sigma \not\in H_C$. Then, $\text{Tr}(\theta(C, C')(\text{Frob}_p)) = \text{Tr}(\theta_C \circ \lambda_p(\text{Frob}_p)) = 0$. □

### 4 The genus 2 case

Throughout this section, $C$ denotes a genus 2 curve defined over $\mathbb{Q}$. Let us recall some basic facts that may be found in [CGLR99]. It is well known that $C$ admits an affine model given by a hyperelliptic equation $Y^2 = f(X)$, where $f(X) \in \mathbb{Q}[X]$. Any element $\alpha \in \text{Aut}(C)$ can then be written in the form
$$\alpha(X, Y) = (\frac{mX + n}{pX + q}, \frac{mq - np}{(pX + q)^3}Y),$$
for unique $m, n, p, q \in K$. Moreover, the map
$$\text{Aut}(C) \rightarrow \text{GL}_2(K), \quad \alpha \mapsto \begin{pmatrix} m & n \\ p & q \end{pmatrix}$$
defines a 2-dimensional faithful representation of $\text{Aut}(C)$. We will often identify an automorphism of $C$ with its corresponding matrix. Note that $w(X, Y) = (X, -Y)$ is always an automorphism of $C$, called the hyperelliptic involution of $C$, which lies in the center $\text{Z}(\text{Aut}(C))$ of $\text{Aut}(C)$.

The group $\text{Aut}(C)$ is isomorphic to one of the groups
$$C_2, \ C_2 \times C_2, \ D_8, \ D_{12}, \ 2D_{12}, \ \tilde{S}_4, \ C_2 \times C_5,$$
where $2D_{12}$ and $\tilde{S}_4$ denote certain double covers of the dihedral group of 12 elements $D_{12}$ and the symmetric group on 4 letters $S_4$. Completing the study initiated by Clebsch and Bolza, Igusa [Igu60] computed the 3-dimensional moduli variety $\mathcal{M}_2$ of genus 2 curves defined over $\mathbb{Q}$. Generically, the only non-trivial automorphism of a curve in $\mathcal{M}_2$ is the hyperelliptic involution and, thus, $\text{Aut}(C) \simeq C_2$. The curves with $\text{Aut}(C)$ containing $C_2 \times C_2$ constitute a surface in $\mathcal{M}_2$. The moduli points corresponding to curves such that $\text{Aut}(C)$ contains $D_8$ or $D_{12}$ describe two curves contained in this surface. The curves with $\text{Aut}(C) \simeq 2D_{12}, \tilde{S}_4, \text{or } C_2 \times C_5$ correspond to three isolated points of $\mathcal{M}_2$. 9
In this section, we will explicitly compute the twisting representation $\theta_C$ of $C$ and the decomposition of $\theta(C,C') \otimes V_j(C)$ when $\text{Aut}(C) \simeq D_8$ or $D_{12}$. In both cases, the irreducible characters of $G_C$ will be denoted $\chi_i$, even though they refer to different groups (we will always refer the reader to the corresponding character table in Section 5). We will denote by $g_i$ a representation of character $\chi_i$.

**Lemma 4.1.** If $\text{Aut}(C)$ is non-abelian, then $J(C) \sim_K E^2$, where $E$ is an elliptic curve defined over $K$.

**Proof.** It is straightforward to check that $\text{Aut}(C)$ contains a non-hyperelliptic involution $u$. Then the quotient $E = C/\langle u \rangle$ is an elliptic curve defined over $K$ (see Lemmas 2.1 and 2.2 in [CGLR99]). The injection $E \hookrightarrow J(C)$ is also defined over $K$ and Poincaré Decomposition Theorem ensures the existence of an elliptic curve $E'$ defined over $K$ such that $J(C) \sim_K E \times E'$. Since $\text{End}_K(J(C))$ contains $\text{Aut}(C)$, it is non-abelian and so $\text{End}_K(J(C)) \simeq \mathbb{M}_2(\text{End}_K(E))$, from which $E \sim_K E'$.

**Remark 4.1.** From now on, for the cases $\text{Aut}(C) \simeq D_8$ or $D_{12}$, we will make the assumption that the elliptic quotient $E$ does not have complex multiplication, i.e., $\text{End}^0_K(J(C)) \simeq \mathbb{M}_2(\mathbb{Q})$. This only excludes a finite number of $\mathbb{Q}$-isomorphism classes. Indeed, curves with $\text{Aut}(C) \simeq D_8$ or $D_{12}$ defined over $\mathbb{Q}$ are parameterized by rational values of their absolute invariant $u$ (see subsections 4.1 and 4.2 for the details). According to Proposition 8.2.1 of [Car01] the $j$-invariant of the elliptic quotient $E$ has two possibilities

$$j(E) = \begin{cases} 
\frac{2^{3}(3+10\sqrt{11})^3}{(1+2\sqrt{11})(1+2\sqrt{11})^2} & \text{if } \text{Aut}(C) \simeq D_8, \\
\frac{2^{3}(3+5\sqrt{11})^3}{(1+2\sqrt{11})(1+2\sqrt{11})^2} & \text{if } \text{Aut}(C) \simeq D_{12}.
\end{cases}$$

Since the degree of the extension $\mathbb{Q}(j(E))/\mathbb{Q}$ is 1 or 2 and the number of quadratic imaginary fields of class number 1 or 2 is finite, we deduce that there exists only a finite number of rational absolute invariants $u$ for which $E$ has CM. According to the table on page 112 of [Car01], for $\text{Aut}(C) \simeq D_8$ these values of $u$ are:

$$\begin{array}{cccccccc}
81 & 3969 & -81 & 1 & 9 & 12 & 81 & 81 \\
196 & 16900 & 700 & 52 & 32 & 9 & 32 & 325 \\
2401 & 9801 & 6480 & 194481 & 96059601 \\
9600 & 39200 & 25920 & 777925 & 384238400
\end{array}$$

(4.1)

For $\text{Aut}(C) \simeq D_{12}$ the values of $u$ for which $E$ has CM are:

$$\begin{array}{cccccccc}
\frac{4}{25} & -4 & 1 & 1 & 27 & 4 & 125 & 20 \\
\frac{11}{11} & 20 & 2 & 100 & 17 & 484 & 81 & 1025 \\
3025 & 3025 & 2500001
\end{array}$$

(4.2)

**Remark 4.2.** By Lemma 4.1, if $\text{Aut}(C) \simeq D_8$ or $D_{12}$, then for every twist $C'$ of $C$, one has that

$$\text{End}^0_K(J(C')) = \text{End}^0_K(J(C)) \simeq \mathbb{M}_2(\text{End}_K(E)).$$

In other words, every twist $C'$ of $C$ is a $\theta_C$-twist of $C$. 

10
4.1 Aut(C) \simeq D_8

Proposition 4.1 (Proposition 2.1 of [CQ07]). There is a bijection between the \( \overline{Q} \)-isomorphism classes of genus 2 curves defined over \( Q \) with \( \text{Aut}(C) \simeq D_8 \) and the open set of the affine line \( Q^* \setminus \{ 1/4, 9/100 \} \), given by associating to each \( u \in Q^* \setminus \{ 1/4, 9/100 \} \) the projective curve of equation

\[
Y^2Z^3 = X^5 + X^3Z^2 + uXZ^4.
\]

As follows from Proposition 4.4 of [CQ07], the curve in the previous proposition is \( \overline{Q} \)-isomorphic to

\[
C = C_u: Y^2Z^4 = X^6 - 8X^5Z + \frac{3}{u}X^4Z^2 + \frac{3}{u^2}X^2Z^4 + \frac{8}{u^2}XZ^6 + \frac{1}{u^3}Z^6. \tag{4.3}
\]

where we have chosen parameters \( z = 0, s = 1 \) and \( v = 1/u \). Its group of automorphisms is computed loc. cit. in Proposition 3.3, and it is generated by

\[
U = \begin{pmatrix} 1/\sqrt{2} & 1/\sqrt{2u} \\ \sqrt{u}/2 & -1/\sqrt{2} \end{pmatrix}, \quad V = \begin{pmatrix} 0 & -1/\sqrt{u} \\ \sqrt{u} & 0 \end{pmatrix},
\]

from which we see that \( K = Q(\sqrt{u}, \sqrt{2}) \). Note that \( U \) and \( V \) satisfy the relations \( U^2 = 1, V^4 = 1 \) and \( UV = VU \). For the character table of the group \( G_C \), see in Section 5 Table 1 if \( u \) and \( 2u \notin Q^* \); Table 2 if \( u \in Q^* \) and Table 3 if \( 2u \notin Q^* \).

Proposition 4.2. One has

\[
\text{Tr} \theta_C = \begin{cases} 
\chi_{11} & \text{if } u \text{ and } 2u \notin Q^*, \\
\chi_9 + \chi_{10} & \text{if } u \in Q^*, \\
\chi_6 + \chi_7 & \text{if } 2u \in Q^*.
\end{cases}
\]

Moreover, \( \text{Res}_{H_C}^{G_C} \chi_9 = \text{Res}_{H_C}^{G_C} \chi_{10} \) in the second case, and \( \text{Res}_{H_C}^{G_C} \chi_6 = \text{Res}_{H_C}^{G_C} \chi_7 \) in the third case.

Proof. The dimension of \( \theta_C \) is 4. Suppose that \( u \) and \( 2u \notin Q^* \). By looking at the column of the conjugacy class 2A in Table 1 one sees that \( \rho_{11} \) is the only faithful representation of dimension 4 of \( G_C \).

One can also directly compute the representation \( \theta_C \). Denote by \( \alpha^* \) the image of \( \alpha \in \text{Aut}(C) \) by the inclusion \( \text{Aut}(C) \to \text{End}_{\overline{Q}}^c(J(C)) \). We will prove that \( \text{End}_{\overline{Q}}^c(J(C)) = (1^*, U^*, V^*, U^*V^*)_Q \). Indeed, it is enough to see that \( 1^*, U^*, V^* \) and \( U^*V^* \) are linearly independent. Suppose that for certain \( \lambda_i \) in \( Q \), one has \( \lambda_11^* + \lambda_2U^* + \lambda_3V^* + \lambda_4U^*V^* = 0 \). Conjugating by \( V^* \) one obtains \( \lambda_11^* - \lambda_2U^* + \lambda_3V^* - \lambda_4U^*V^* = 0 \), which implies \( \lambda_11^* + \lambda_3V^* = 0 \) and thus \( \lambda_1 = \lambda_3 = 0 \). Analogously, one has \( \lambda_2U^* + \lambda_4U^*V^* = 0 \), which implies \( \lambda_2 = \lambda_4 = 0 \) and \( \tau(\sqrt{2}) = -\sqrt{u} \).

Now, \( H_C \) can be computed by observing that \( vU = UV, V^4 = V^3, U^2 = UV, V^2 = V \).

Suppose that \( u \in Q^* \). By looking at the column of the conjugacy class 2A in Table 2 one sees that either \( \rho_9 \) or \( \rho_{10} \) is a constituent of \( \theta_C \), since otherwise \( \theta_C \) would not be faithful. Since \( \rho_9 = \rho_{10} \), we deduce that \( \theta_C = \rho_9 + \rho_{10} \). Moreover, by Lemma 3.1 \( \text{Res}_{H_C}^{G_C} \theta_C = 2 \cdot \rho \), where \( \rho \) is a representation of \( H_C \simeq D_8 \). Since the only faithful representation of \( D_8 \) is irreducible, it follows that \( \text{Res}_{H_C}^{G_C} \rho_9 = \text{Res}_{H_C}^{G_C} \rho_{10} = \rho \). The case \( 2u \in Q^* \) is analogous. \( \Box \)
Proposition 4.2 and Theorem 3.1 imply the following result.

Corollary 4.1. If $C'$ is a twist of $C$ such that $V_{t}(C')$ is a simple $\mathbb{Q}[G_{K}]$-module, then

$$
\theta(C, C') \otimes V_{t}(C') \simeq \begin{cases} 
\mathbb{Q}[\text{Gal}(K/\mathbb{Q})] \otimes V_{t}(C') & \text{if } u \text{ and } 2u \not\in \mathbb{Q}^{*}2, \\
2 \cdot \mathbb{Q}[\text{Gal}(K/\mathbb{Q})] \otimes V_{t}(C') & \text{if } u \text{ or } 2u \in \mathbb{Q}^{*}2.
\end{cases}
$$

Proof. If $u \in \mathbb{Q}^{*}2$, the fact that $\text{Tr} \theta_{C} = x_{9} + x_{10}$ together with $g^{2}/2 = [K: \mathbb{Q}] = 2$, guarantees that we are in case (II) of Theorem 3.1. The case $2u \in \mathbb{Q}^{*}2$ is analogous. If $u$ and $2u \not\in \mathbb{Q}^{*}2$, then we are in case (I). \[\square\]

4.2 \quad \text{Aut}(C) \simeq D_{12}

Proposition 4.3 (Proposition 2.2 of [CQ07]). There is a bijection between the $\mathbb{Q}$-isomorphism classes of genus 2 curves defined over $\mathbb{Q}$ with $\text{Aut}(C) \simeq D_{12}$ and the open set of the affine line $\mathbb{Q}^{*} \times \{1/4, -1/50\}$, given by associating to each $u \in \mathbb{Q}^{*} \setminus \{1/4, -1/50\}$ the projective curve of equation

$$
Y^{2}Z^{4} = X^{6} + X^{3}Z^{3} + uZ^{6}.
$$

As follows from Proposition 4.9 of [CQ07], the curve of the previous proposition is $\mathbb{Q}$-isomorphic to

$$
C = C_{u} : Y^{2}Z^{4} = 27uX^{6} - 2916u^{2}X^{5}Z + 243u^{2}X^{4}Z^{2} + 29160u^{3}X^{3}Z^{3} + 729u^{3}X^{2}Z^{4} - 26244u^{4}XZ^{5} + 729u^{4}Z^{6}.
$$

This curve corresponds to the curve appearing in Proposition 4.9 of [CQ07], with choice of parameters $z = 0$, $s = u$ and $v = u/3$. Its group of automorphisms is computed loc. cit. in Proposition 3.5, and is generated by

$$
U = \left( \begin{array}{cc} 0 & \sqrt{u}/3 \\ 3/\sqrt{u} & 0 \end{array} \right), \quad V = \left( \begin{array}{cc} 1/2 & -\sqrt{u}/12 \\ 3\sqrt{3}/\sqrt{4u} & 1/2 \end{array} \right),
$$

from which we see that $K = \mathbb{Q}(\sqrt{u}, \sqrt{3})$ (observe the change of two signs in the matrix $V$ with respect to [CQ07]). Note that $U$ and $V$ satisfy the relations $U^{2} = 1$, $V^{6} = 1$ and $UV = V^{5}U$. For the character table of the group $G_{C}$, see in Section 5 Table 4 if $u$ and $3u \not\in \mathbb{Q}^{*}2$; Table 5 if $u \in \mathbb{Q}^{*}2$; and Table 6 if $3u \in \mathbb{Q}^{*}2$.

Proposition 4.4. One has

$$
\text{Tr} \theta_{C} = \begin{cases} 
\chi_{15} & \text{if } u \text{ and } 3u \not\in \mathbb{Q}^{*}2, \\
\chi_{i} + \chi_{j} \text{ for } i \neq j \in \{10, 11, 12\} & \text{if } u \in \mathbb{Q}^{*}2, \\
\chi_{8} + \chi_{9} & \text{if } 3u \in \mathbb{Q}^{*}2.
\end{cases}
$$

Moreover, $\text{Res}_{H_{C}}^{G_{C}} \chi_{i} = \text{Res}_{H_{C}}^{G_{C}} \chi_{j}$ in the second case, and $\text{Res}_{H_{C}}^{G_{C}} \chi_{8} = \text{Res}_{H_{C}}^{G_{C}} \chi_{9}$ in the third case.

Proof. The dimension of $\theta_{C}$ is 4. Suppose that $u$ and $3u \not\in \mathbb{Q}^{*}2$. By Lemma 4.2 below, and by looking at the column of the conjugacy class 2A in Table 4 one sees that $\varrho_{13}$, $\varrho_{14}$ and $\varrho_{15}$ are the only possible constituents of $\theta_{C}$. We deduce
that \( \theta_C \simeq \varrho_{15} \) from the fact that none of the representations \( 2 \cdot \varrho_{13}, 2 \cdot \varrho_{14} \) and \( \varrho_{13} \oplus \varrho_{14} \) is faithful.

One can also directly compute the representation \( \theta_C \). Analogously to the case \( \text{Aut}(C) \simeq D_4 \) one has \( \text{End}_K^0(J(C)) = \langle 1^*, U^*, V^*, U^*V^* \rangle \). Moreover, since the algebra \( \langle 1^*, V^* \rangle \) has no zero divisors, one deduces that \( V^* = V^* - 1 \).

Let \( \sigma, \tau \in \text{Gal}(K/\mathbb{Q}) \) be such that \( \sigma(\sqrt{u}) = -\sqrt{u} \) and \( \tau(\sqrt{3}) = -\sqrt{3} \). Then \( \sigma U = UV^3, \sigma V = V^5, \tau U = U, \tau V = V^5 \).

Suppose that \( u \in \mathbb{Q}^{*2} \). By Lemma 4.1, \( \text{Res}_{H_C}^{\mathbb{Q}C} \varrho_2 = 2 \cdot \varrho \). The only faithful representation of \( H_C \simeq D_{12} \) is irreducible. This, together with the fact that the dimension of the irreducible representations of \( G_C \) is at most 2 (see Table 5), implies that \( \theta_C \) is the sum of two irreducible representations of dimension 2. The only sums of two irreducible representations of dimension 2 of \( G_C \), which are faithful are \( \chi_{10} + \chi_{11}, \chi_{11} + \chi_{12}, \) or \( \chi_{10} + \chi_{12} \). The case \( 3u \in \mathbb{Q}^{*2} \) is analogous.

**Lemma 4.2.** Let \( C \) be a smooth projective hyperelliptic curve. Let \( \psi \) be the hyperelliptic involution of \( C \). Then, one has

\[
\text{Tr} \theta_C((w, \text{id})) = -\dim \text{End}_K^0(J(C)).
\]

**Proof.** Observe that for \( \psi \in \text{End}_K^0(J(C)) \), one has \( \theta_C((w, \text{id})) = -\psi \).

Proposition 4.1 and Theorem 5.1 imply the following result.

**Corollary 4.2.** If \( C' \) is a twist of \( C \) such that \( V_0(C') \) is a simple \( \mathbb{Q}L[G_K]-\)module, then

\[
\theta(C, C') \otimes V_0(C) \cong \begin{cases} 
\mathbb{Q}[\text{Gal}(K/\mathbb{Q})] \otimes V_0(C') & \text{if } u \text{ and } 3u \notin \mathbb{Q}^{*2} \\
2 \cdot \mathbb{Q}[\text{Gal}(K/\mathbb{Q})] \otimes V_0(C') & \text{if } u \text{ or } 3u \in \mathbb{Q}^{*2}.
\end{cases}
\]

**Proof.** If \( u \) and \( 3u \notin \mathbb{Q}^{*2} \), the fact that \( \text{Tr} \theta_C = \chi_{15} \) together with \( g^2 = [K : \mathbb{Q}] = 4 \), guarantees that we are in case (I) of Theorem 5.1. If \( u \) or \( 3u \in \mathbb{Q}^{*2} \), then we are in case (II).

### 4.3 L-functions of twisted genus 2 curves

Now the proof of Theorem 4.2 is immediate. If \( p \) is an unramified prime in \( L/\mathbb{Q} \), then the reciprocal of the characteristic polynomial of \( \text{Frob}_p \) acting on the \( \mathbb{Q}L[G_C]-\)module at the left-hand side of the isomorphism of Corollary 4.1 or Corollary 4.2 is \( L_p(C/\mathbb{Q}, \theta_C \circ \lambda_G, T) \). Recall that \( f \) denotes the residue class degree of \( p \) in \( K/\mathbb{Q} \). The result follows from the fact that the right-hand side of the isomorphism of Corollary 4.1 or Corollary 4.2 is of the form \( g \otimes V_0(C') \), where \( g \) is a 4-dimensional representation of \( \text{Gal}(K/\mathbb{Q}) \) such that \( g(\text{Frob}_p) \) has four eigenvalues equal to 1 if \( f = 1 \), and two eigenvalues equal to 1, and two equal to -1 if \( f = 2 \).

Observe that thanks to Theorem 1.2 from the local factor \( L_p(C/\mathbb{Q}, T) \) and the representation \( \theta(C, C') \simeq \theta_C \circ \lambda_G \), either the polynomial \( L_p(C'/\mathbb{Q}, T) \) or the product \( L_p(C'/\mathbb{Q}, T) \cdot L_p(C'/\mathbb{Q}, -T) \) can be determined. The indeterminacy of the sign of \( a'_p \) follows from the product \( L_p(C'/\mathbb{Q}, T) \cdot L_p(C'/\mathbb{Q}, -T) \), can not be handled with the relation

\[
\text{sgn}(\text{Tr}(\theta(C, C')(\text{Frob}_p))) = \text{sgn}(a_p \cdot a'_p).
\]

from Proposition 5.2 since this relation only holds for \( f = 1 \).
5 Appendix: Character tables of twisting groups

In the following tables, the notation GAP\((n, m)\) indicates the \(m\)-th group of order \(n\) in the ordered list of finite groups of GAP.

| Class | 1A | 2A | 2B | 2C | 2D | 2E | 4A | 4B | 4C | 8A | 8B |
|-------|----|----|----|----|----|----|----|----|----|----|----|
| Size  | 1  | 1  | 4  | 4  | 2  | 2  | 2  | 2  | 2  | 2  | 2  |
| \(\chi_1\) | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  |
| \(\chi_2\) | 1  | 1  | -1 | -1 | -1 | -1 | -1 | -1 | -1 | -1 | -1 |
| \(\chi_3\) | 1  | 1  | -1 | -1 | -1 | -1 | -1 | -1 | -1 | -1 | -1 |
| \(\chi_4\) | 1  | 1  | -1 | -1 | -1 | -1 | -1 | -1 | -1 | -1 | -1 |
| \(\chi_5\) | 1  | 1  | -1 | -1 | 1  | 1  | -1 | 1  | -1 | 1  | -1 |
| \(\chi_6\) | 1  | 1  | -1 | -1 | -1 | -1 | 1  | 1  | -1 | -1 | -1 |
