Microwave-assisted synthesis and antioxidant properties of hydrazinyl thiazolyl coumarin derivatives

Hasnah Osman1*, Afsheen Arshad1, Chan Kit Lam2 and Mark C Bagley3*

Abstract

Background: Coumarin derivatives exhibit a wide range of biological properties including promising antioxidant activity. Furthermore, microwave-assisted organic synthesis has delivered rapid routes to N- and O-containing heterocycles, including coumarins and thiazoles. Combining these features, the use of microwave-assisted processes will provide rapid access to a targeted coumarin library bearing a hydrazino pharmacophore for evaluation of antioxidant properties.

Results: Microwave irradiation promoted 3 of the 4 steps in a rapid, convergent synthesis of a small library of hydrazinyl thiazolyl coumarin derivatives, all of which exhibited significant antioxidant activity comparable to that of the natural antioxidant quercetin, as established by DPPH and ABTS radical assays.

Conclusions: Microwave dielectric heating provides a rapid and expedient route to a series of hydrazinyl thiazolyl coumarins to investigate their radical scavenging properties. Given their favourable properties, in comparison with known antioxidants, these coumarin derivatives are promising leads for further development and optimization.

Keywords: Coumarins, Thiazoles, Antioxidant activity, Microwave synthesis

Background

The synthesis and biological activities of coumarin derivatives occupy an important position in heterocyclic chemistry as well as in medicinal chemistry. The compounds containing this heterocyclic motif are widely found as additives in food, in cosmetic products, as pharmaceutical agents [1] and as luminescent materials [2]. They have pronounced medicinal value as anticoagulants [3], free radical scavengers [4,5], and as lipoxygenase [6] and cyclooxygenase inhibitors [7]. Moreover, many coumarins exhibit high antibacterial [8], antifungal [9] and cytotoxic activities [10]. The incorporation of a 3-thiazolyl substituent can further enhance the activity of this pharmacophore: thiazolyl coumarins have been reported to exhibit anticonvulsant [11], anticancer, antimicrobial [12], analgesic and anti-inflammatory properties [13] and display good activity against Mycobacterium tuberculosis [14] and Helicobacter pylori [15]. The pathophysiology of many of the above-mentioned diseases, and others, has been linked with oxidative stress, produced in our body as a result of various oxidation processes essential for life. Although the importance of antioxidants to prevent the progression of age-related diseases, or interfere in the ageing process itself, could be contested [16,17], their role in enzymatic and non-enzymatic defense mechanisms in both the lipid and aqueous phase is well established [18]. Given that coumarin and its derivatives are well-known as antioxidants [19], we set out to access a series of thiazolyl coumarin derivatives, rapidly and in a convergent manner, to explore their antioxidant properties. Previously we have reported the synthesis and crystalline structure of various thiazolyl coumarin derivatives prepared by conventional methods, including the synthesis of a series of hydrazinyl thiazolyl coumarins [20-24]. Given the versatility and capability of microwave-assisted synthesis for rapid delivery of compounds of biological interest [25-28], our previous success in the use of microwave irradiation for the rapid synthesis of thiazoles of biological interest [29,30], and the
previous application of this technology in the synthesis of coumarins, both on small and large scale [31–34], as well as thiazoyl coumarin Schiff bases [35], we set out to investigate a rapid microwave-assisted synthesis of a hydrazinyl thiazolyl coumarin library for evaluation of in vitro antioxidant activity by DPPH radical and ABTS radical cation assays, using the natural antioxidant quercetin and a synthetic antioxidant (butylatedhydroxytoluene) as reference standards.

Results and discussion

3-(Bromoacetyl)coumarin (4), a key precursor of Hantzsch thiazole synthesis for the hydrazinyl thiazolyl coumarin library, was prepared by a two-step sequence (Scheme 1). Firstly Knoevenagel condensation, with spontaneous α-pyrone 3 formation, was investigated by heterocyclocondensation of salicylaldehyde (1) and ethyl acetoacetate (2) under microwave irradiation using a range of conditions (Table 1). It has been reported that the use of microwave heating is beneficial for 3-acetylcoumarin synthesis, allowing for low catalyst loadings and short reaction times to limit the generation of unwanted side products [33,34]. Although solvent-free conditions have been used for α-pyrone 3 formation under microwave irradiation [31,32] and conventional heating [36], in the presence of a catalytic amount of piperidine or L-proline, these give rise to widely varying reaction times, operating temperatures and thus chemical yields [31]. In our hands (entry 1), the solvent-free process resulted in a rapid rise of pressure and so was discarded in favour of the more reliable Leadbeater method, carried out in ethanol solvent, which has been reported to proceed in reasonable yield (67–81%) on multigram scale in sealed vessel microwave apparatus [33] and more recently in a large scale batch reactor [34]. In our modified procedure, on 18 mmol scale, with a small excess of carbonyl compound 2 (1.3 equiv), the use of piperidine base (entries 6–8) seemed superior to the L-proline catalyst (entries 2–5) giving 3-acetylcoumarin (3) in 99% isolated yield in a reaction time of only 5 min (entry 8) following purification by recrystallization.

With a rapid and highly efficient route to acetylcoumarin 3 established, the first of the building blocks for Hantzsch thiazole synthesis, bromoacetylcoumarin 4, was prepared in 68% yield by the electrophilic bromination of acetylcoumarin 3, in CHCl₃, according to the method of Gursoy and Karali [14] (Scheme 1). Furthermore the second, thioamide, component was provided by the condensation of thiosemicarbazide 5 and one member of a subset of benzaldehydes 6 or naphthaldehydes 8 in a microwave-assisted condensation. Microwave irradiation of a methanolic solution of a range of these precursors at 120°C for 10 min (Scheme 2) gave thiosemicabazones 7 or 9, respectively, in excellent isolated yield (70–92%) after purification by recrystallization (Table 2). The efficiency of the microwave-assisted procedure compared highly favourably, in terms of isolated yield and reaction time, with the condensation carried out using more traditional methods, at reflux in MeOH in the presence of AcOH for 1–4 h, using the same isolation and purification regime.

Given that microwave irradiation has been used before in the synthesis of thiazole derivatives of biological interest [29,30,37–39] and that, in particular, Hantzsch thiazole synthesis conducted in ethanol was successful in generating thiazoles in good yields for evaluation of antiproliferative activity [40], the Hantzsch synthesis of thiazolyl coumarins 10a–h from corresponding building blocks was investigated under related conditions (Scheme 3). Microwave irradiation of semicarbazone 7,9 and bromoketone 4 in ethanol at 60°C for 10 min (hold time) followed by treatment with ammonium hydroxide (5%) gave coumarin derivatives 10a–h in very good yield (71–80%) (Table 3). In all cases, the isolated yield after purification by recrystallization was closely comparable with traditional

conductive heating methods (see Table 3). The identity and purity was confirmed by analysis of spectroscopic and mass spectrometric data and by comparing the melting point with literature values [20]. The use of microwave irradiation had facilitated and accelerated 3 out of the 4 steps in the convergent synthesis of thiazolyl coumarins 10a-h, including two heterocyclocondensations (α-pyrone formation and Hantzsch thiazole synthesis) and semicarbazone formation, to provide an extremely rapid route to a focused library for examination of antioxidant properties.

Hydrazino-thiazole derivatives have been shown recently to possess radical scavenging ability and some simple structure-activity relationships have been described for a small library of compounds [41]. The antioxidant properties of this motif were evaluated quickly and efficiently using a small library of compounds [41]. The antioxidant properties of this motif were evaluated quickly and efficiently using a small library of compounds [41]. model [42] in which the decrease in the strong absorption band at \(\nu = 517\) nm due to the unpaired electron in DPPH decreased stoichiometrically on scavenging an electron or hydrogen atom. Using the DPPH free radical assay, according to a modification of our previously reported procedure [43], the radical scavenging activity of this new series of thiazolyl coumarins 10a-h was determined and expressed as IC₅₀ values [41,43], which is the concentration of tested compound required to scavenge 50% of the DPPH radical concentration (0.11 mM in this case on dilution). All of the DPPH assays were conducted in triplicate and both a synthetic antioxidant, 2,6-di-tert-butyl-4-methylphenol (BHT), and the natural antioxidant quercetin were used as reference standards. The results from the DPPH radical scavenging assay were validated by 2,2′-azinobis (3-ethylbenzothiazoline-6-sulfonate) (ABTS) assay [42,44], which established IC₅₀ values for each tested compound to trap the ABTS⁺ radical. For consistency, IC₅₀ values in ABTS assay were established in triplicate and compared with quercetin, again, and Trolox, which is a common reference antioxidant for interaction with ABTS⁺ [42,44-46]. As expected, DPPH radical assay indicated that radical scavenging activity was dose dependent and increased with the concentration of the tested compound (Figure 1). The IC₅₀ values of thiazolyl coumarins 10a-h in the DPPH assay were found to be in the range 16–85 \(\mu\)M (Table 4), displaying excellent antioxidant activity above and beyond that of BHT and comparable to that of quercetin (Figure 2). It was worthy to note that compounds 10a, 10c, 10d, 10e, 10f and 10h exhibited very high activity against the DPPH radical (at a concentration of 0.11 mM) with IC₅₀ values in the order of 16–30 \(\mu\)M. The activity of this thiazolyl coumarin library compared closely with other known hydrazino-thiazoles (IC₅₀ 15–60 \(\mu\)M at a DPPH radical concentration of 0.1 mM) [41] implying that the coumarin and phenolic functions had not adversely affected antioxidant activity. The activity of these compounds was attributed for the most part to the hydrazinothiazole functionality but clearly was modulated...
and enhanced by the incorporation of other unique groups. The presence of the hydrazino N-H group (Scheme 4) and the phenolic hydroxyl were viewed as important structural features, both having the ability for hydrogen atom transfer (HAT) to the DPPH free radical to give a resonance stabilized radical 11a-f. The mesomeric stabilization of this radical, in particular through the addition of electron donating aromatic units could contribute to radical scavenging ability, with notable improvements observed for 2-hydroxy 10a and 4-hydroxyphenyl 10c analogues over the 3-hydroxy precursor 10b (Table 4, entry 2). Alternatively sequential proton loss electron transfer (SPLET) could compete with HAT (Scheme 4c) for phenolic scavengers (ArOH) as has been described for curcumin [42]. In this latter case, synergistic contributions to the activity of phenolic and hydrazino scavengers could not be ruled out but these features were not explored further. The presence of hydroxyl groups in compounds 10a-f and 10h appeared to contribute to the antioxidant activity of these compounds and when absent resulted in a dramatic loss of radical scavenging ability (Table 4, compare lower activity of 10g in entry 7 with entry 8), suggesting the involvement of a SPLET mechanism. The reaction of the DPPH radical with scavengers (Scheme 4a) in general suggests a 1:1 stoichiometry of reaction at high scavenger concentration. When the concentration of the tested compounds is significantly lower than the DPPH radical, as could be the case for compounds with potent IC50 values, the remaining DPPH radical may combine with the hydrazinyl thiazolyl radical 11a-f (Scheme 4b) and thus, the stoichiometry of the reaction could appear higher than 1:1 [41]. Finally, on review it was bromophenyl analogue 10e that exhibited the highest activity in the DPPH assay (Table 4, entry 5) even exceeding the activity of the natural antioxidant quercetin (entry 10). The findings from the DPPH assays correlated well with IC50 values derived in ABTS experiments. The ABTS radical was generated by treatment with the strong oxidizing agent K2S2O8 and then reduced by the addition of the antioxidant; this was observed by the suppression of the characteristic long wave absorption of ABTS•+. For the most part, the mean IC50 values were of very similar magnitude with minimal differences between the ABTS and DPPH values (Table 4), an observation that has been made before in measuring antioxidant activities of sorghum products [47]. Thus no matter which assay was used, the compounds exhibited the

1 Isolated yield after microwave dielectric heating in EtOH at 60°C for 10 min (hold time) in a sealed tube using a CEM Discover single-mode microwave synthesizer by moderation of the initial magnetron power (30 W), followed by treatment with aqueous base and purification by recrystallization.

2 Isolated yield after reaction by traditional conductive heating at reflux in EtOH–CHCl3 for 1–4 h, basification with NH3 (aq) and purification by recrystallization (see reference 20 for details). n/a Experiment not investigated.
same activity trends and SAR (Figure 2), validating the reliability of both techniques. However, it was noted that there appeared to be greater consistency with the DPPH data and greater variability in the ABTS IC50 values according to the observed standard deviations.

Conclusions
The synthesis and antioxidant activity of hydrazinyl thiazolyl coumarin derivatives have been reported. Microwave irradiation promoted 3 out of the 4 steps to establish an extremely rapid, convergent and highly efficient route to the target library. All of the compounds were purified by recrystallization and obtained in good isolated yields, with spectroscopic and physical data that fully supported the proposed structures. DPPH and ABTS assays indicated that almost all of the synthesized hydrazinyl thiazolyl coumarin derivatives (10a, 10c, 10d, 10e, 10f and 10h) had significant radical scavenging activity that was comparable or better than the known antioxidants, quercetin, BHT and Trolox. The thiazole, hydrazino, and phenolic moieties are the likely structural components contributing to free radical scavenging activity. However, the facile incorporation of the coumarin motif offers an opportunity to further optimize radical scavenging activity in the future for hit-to-lead development of new and improved synthetic antioxidants.

Experimental
Preparation of 3-acetyl-2H-chromen-2-one (3) by knoevenagel condensation
Piperidine (0.1 mL) was added dropwise to a mixture of salicylaldehyde (2.0 mL, 18 mmol) and ethyl acetoacetate (3.0 mL, 24 mmol) in EtOH (1.0 mL). The reaction mixture was stirred under microwave radiation for 1–10 min (hold time) at 50 or 120°C, resulting in the

![Figure 1: Evaluation of antioxidant properties by DPPH assay.](http://journal.chemistrycentral.com/content/6/1/32)
formation of a yellow solid. Purification by recrystallization (EtOH) gave the title compound 3 (2.8 g, 93%) (Table 2, entry 4) as fine yellow needles, mp 117–118°C (Lit. mp 119–121°C [48]) with identical spectroscopic properties.

**Bromination of acetylcoumarins**

3-Acetyl-2H-chromen-2-one (3) (20 g, 0.11 mol), obtained from the combined product of a series of parallel experiments, was dissolved in alcohol-free CHCl₃ (20 mL) and a solution of Br₂ (5.45 mL, 0.11 mol) in CHCl₃ (20 mL) was added dropwise. The reaction mixture was allowed to stirring for 2 h, and the resulting mixture was poured into ice-water (100 mL). The aqueous layer was extracted with CHCl₃ (3 × 50 mL), and the combined organic layers were washed with water (50 mL), dried (Na₂SO₄), and concentrated in vacuo to give a yellow solid (5.3 g).

**Figure 2** Comparing antioxidant activities using DPPH and ABTS assays.

![Antioxidant activity (µM) of hydrazinyl thiazolyl coumarin derivatives](image)

**Scheme 4** DPPH radical scavenging reactions of hydrazinyl thiazolyl coumarins 10a-h and phenolic (ArOH) scavengers [41,42].
added dropwise from a dropping funnel with constant stirring at 0–5°C. After 3 h, a dark yellow solid separated. The reaction mixture was heated for 15 min at reflux, cooled and CHCl₃ was removed using a rotary evaporator. Purification by recrystallization (glacial AcOH) gave 3-bromoacetocoumarin 4 (19 g, 68%) as off-white needles, mp 162–163°C (Lit. mp 160–163°C [11]); IR (KBr) ν max 2930 (C-H aliphatic), 1731 (C = O), 1686 (O-C = O); ¹H NMR (400 MHz, CDCl₃) δ 8.66 (1H, s), 7.69–7.75 (2H, m), 7.39–7.44 (2H, m), 4.79 (2H, s).

General procedure for the preparation of thiosemicarbazones 7a-f or 9a,b from aldehydes 6a-f or 8a,b, respectively
Thiosemicarbazide (5) (0.46 g, 5.00 mmol) was added slowly to a stirred solution of salicylaldehyde (0.11 mL, 5.00 mmol) in hot absolute EtOH (5 mL). The resulting solution was heated at 120°C for 10 min (hold time) under microwave irradiation. The mixture was cooled in a stream of compressed air, then allowed to cool further in an ice bath for 30 min to give a colourless precipitate, which was filtered and washed with cold water. Purification by recrystallization (95% EtOH) gave (E)-2-(2-hydroxybenzylidene)hydrazinecarbothioamide (7a). A similar procedure was employed for the preparation of the other 2-(benzylidene)hydrazinecarbothioamides 7f-9f.

(E)-2-(2-Hydroxybenzylidene)hydrazinecarbothioamide (7a) (0.68 g, 70%) was obtained as colourless crystals, mp 208–210°C (Lit. mp 210°C [49]); IR (KBr) ν max 3462, 3415 (NH₂), 3374 (OH), 3215 (NH), 1610 (C = N), 1230 (C = S); with identical spectroscopic properties. E-2-(3-Hydroxybenzylidene)hydrazinecarbothioamide (7b) (0.80 g, 82%) was obtained as light brown crystals, mp 166–168°C (Lit. mp 168–170°C [50]); IR (KBr) ν max 3458, 3409 (NH₂), 3365 (OH), 3260 (NH), 1614 (C = N), 1225 (C = S); with identical spectroscopic properties. (E)-2-(4-Hydroxybenzylidene)hydrazinecarbothioamide (7c) (0.69 g, 71%) was obtained as colourless crystals, mp 214–216°C (Lit. mp 218–219°C [46]); IR (KBr) ν max 3469, 3414 (NH₂), 3377 (OH), 3235 (NH), 1610 (C = N), 1231 (C = S); with identical spectroscopic properties. (E)-2-(5-Bromo-2-hydroxybenzylidene)hydrazinecarbothioamide (7e) (1.0 g, 78%) was obtained as a beige solid, mp 234–236°C (Lit. mp 238.5°C [51]); IR (KBr) ν max 3543, 3429 (NH₂), 3317 (OH), 3253 (NH), 1612 (C = N), 1217 (C = S); with identical spectroscopic properties. (E)-2-(2-Hydroxy-3-methoxybenzylidene)hydrazinecarbothioamide (7f) (0.80 g, 72%) was obtained as a colourless solid, mp 222–224°C (Lit. mp 220–222°C [52]); IR (KBr) ν max 3458, 3424 (NH₂), 3342 (OH), 3164 (NH), 1594 (C = N), 1140 (C = S); with identical spectroscopic properties.

General procedure for the synthesis of 2-(naphthalen-1-ylmethylene)hydrazinecarbothioamides 9
The experimental procedure employed for the synthesis of (E)-2-(2-hydroxybenzylidene)hydrazinecarbothioamide (7a) was employed using naphthaldehyde 8 (5.0 mmol), thiosemicarbazide (5) (5.0 mmol) and absolute EtOH. Purification by recrystallization, using EtOH–EtOAc (1:2), gave the target compound (9a,b). (E)-2-(Naphthalen-1-ylmethylene)hydrazinecarbothioamide (9a) (1.05 g, 92%) was obtained as a yellow solid, mp 138–140°C (Lit. mp 126°C [53]); IR (KBr) ν max 3448, 3412 (NH₂), 3228 (NH), 1592 (C = N), 1249 (C = S); with identical spectroscopic properties. (E)-2-[2-Hydroxynaphthalen-1-ylmethylene]hydrazinecarbothioamide (9b) (0.88 g, 72%) was obtained as a pink-yellow solid, mp 272–274°C (Lit. mp 271°C [54]); IR (KBr) ν max 3550, 3426 (NH₂), 3236 (NH), 3148 (OH), 1589 (C = N), 1226 (C = S); with identical spectroscopic properties.

Synthesis of hydrazinyl thiazolyl coumarin derivatives 10a-f from bezylidenethiosemicabazides 7a-f
A stirred solution of 3-bromoacetocoumarin (4) (107 mg, 0.40 mmol) and benzylidenethiosemicarbazone 7a-f (78 mg, 0.40 mmol) in EtOH was heated at 60°C for 10 min (hold time) under microwave irradiation and then cooled in a stream of compressed air to give a thick yellow precipitate. The reaction mixture was neutralized with aqueous ammonium hydroxide solution (5%) and the precipitated solid was filtered. Purification by recrystallization, using CHCl₃–EtOH (1:3), gave (E)-3-[2-(2-hydroxybenzylidene)hydrazinyl]thiazol-4-yl)-2H-chromen-2-one (10a). A similar procedure was employed to prepare the target compounds 10b-h, after purification by recrystallization using CHCl₃, EtOH or EtOAc–EtOH.

(E)-3-[2-(2-Hydroxybenzylidene)hydrazinyl]thiazol-4-yl)-2H-chromen-2-one (10a)
The title compound (10a) (107 mg, 74%) was obtained after purification by recrystallization, using CHCl₃–EtOH (1:3), as a yellow solid, mp 270–272°C (Lit. mp 270–272°C [20]); IR (KBr) ν max 3420 (NH), 3212 (OH), 1699 (O-C = O), 1603 (C = N); ¹H NMR (400 MHz, DMSO-d₆) δ 12.30 (1H, br s), 10.41 (1H, br s), 8.55 (1H, s), 8.29 (1H, s), 7.87 (1H, dd, J = 7.5, 1.2 Hz), 7.77 (1H, s), 7.65 (1H, dd, J = 8.0, 1.1 Hz), 7.64 (1H, dd, J = 8.2, 1.1 Hz), 7.47 (1H, d, J = 8.2 Hz), 7.40 (1H, t, J = 7.5 Hz), 7.37 (1H, td, J = 8.0, 1.1 Hz), 6.91 (1H, d, J = 8.0 Hz), 6.89 (1H, t, J = 8.0 Hz).

(E)-3-[2-(3-Hydroxybenzylidene)hydrazinyl]thiazol-4-yl)-2H-chromen-2-one (10b)
The title compound (10b) (116 mg, 80%) was obtained after purification by recrystallization, using EtOAc–EtOH (1:2), as bright yellow crystals, mp 253–254°C (Lit. mp 254–256°C [20]); IR (KBr) ν max 3365 (NH), 3262 (OH), 1698 (O-C = O), 1602 (C = N); ¹H NMR (400 MHz,
DMSO–d$_6$ δ 12.18 (1H, br s), 9.63 (1H, br s), 8.55 (1H, s), 7.98 (1H, s), 7.87 (1H, dd, $J = 7.6, 0.9$ Hz), 7.78 (1H, s), 7.64 (1H, ddd, $J = 8.2, 7.6, 0.9$ Hz), 7.46 (1H, $J = 8.2$ Hz), 7.40 (1H, $J = 7.6$ Hz), 7.23 (1H, $J = 7.6$ Hz), 7.12 (1H, s), 7.05 (1H, $J = 7.8$ Hz), 6.80 (1H, dd, $J = 7.8, 2.4$ Hz).

(E)-3[2-[4-Hydroxybenzylidene]hydrazinyl][thiazol-4-yl]-2H-chromen-2-one (10e)

The title compound (10e) (127 mg, 72%) was obtained after purification by recrystallization, using EtOAc–EtOH (3:1) as a yellow solid, mp 250°C (Lit. mp 251°C); IR (KBr) $\nu$ max 3424 (NH), 1705 (O=C = O), 1600 (C = N); 1H NMR (400 MHz, DMSO–d$_6$) δ 12.15 (1H, br s), 9.93 (1H, br s), 8.60 (1H, s), 7.93 (1H, s), 7.81 (1H, dd, $J = 7.6, 1.0$ Hz), 7.72 (1H, s), 7.67 (1H, ddd, $J = 8.2, 7.6, 1.0$ Hz), 7.55 (2H, $J = 8.6$ Hz), 7.48 (1H, $J = 8.2$ Hz), 7.44 (1H, $J = 7.6$ Hz), 6.88 (2H, $J = 8.6$ Hz).

(E)-3[2-[2-Hydroxy-5-bromobenzylidene]hydrazinyl][thiazol-4-yl]-2H-chromen-2-one (10f)

The title compound (10f) (113 mg, 72%) was obtained after purification by recrystallization, using EtOAc–EtOH (3:1) as a yellow solid, mp 295–296°C (Lit. mp 296–298°C [20]); IR (KBr) $\nu$ max 3430 (NH), 3260 (OH), 1709 (O=C = O), 1583 (C = N); 1H NMR (400 MHz, DMSO–d$_6$) δ 12.05 (1H, br s), 9.93 (1H, br s), 8.60 (1H, s), 7.93 (1H, s), 7.81 (1H, dd, $J = 7.6, 1.0$ Hz), 7.72 (1H, s), 7.67 (1H, ddd, $J = 8.2, 7.6, 1.0$ Hz), 7.55 (2H, $J = 8.6$ Hz), 7.48 (1H, $J = 8.2$ Hz), 7.44 (1H, $J = 7.6$ Hz), 6.88 (2H, $J = 8.6$ Hz).

Methods

1H and 13C NMR spectra were obtained using $d_{6}$-dimethyl sulfoxide at 25°C using a Bruker DPX 400 instrument or 500 Avance instrument operating at 400 or 500 MHz for 1H spectra and 100 MHz for 13C spectra, unless stated otherwise, and were reported in ppm; $J$ values were recorded in Hz and multiplicities were expressed by the usual conventions ($s$ = singlet, $d$ = doublet, $t$ = triplet, $app$ = apparent, $m$ = multiplet). Infra-red (IR) spectra were recorded in the range 4000–600 cm$^{-1}$ on a Perkin-Elmer 1600 series FTIR spectrometer using KBr disks and are reported in cm$^{-1}$. All compounds were examined by analytical thin layer chromatography carried out using aluminium-backed plates coated with Merck Kieselgel 60 GF254, eluting with hexane–ethyl acetate (3:1, v/v).

Microwave-assisted syntheses were carried out at the recorded temperature by the modulation of the initial magnetron power (given in parentheses) in a sealed tube using a CEM Discover single-mode instrument, with magnetic stirring and temperature measurement using the built-in IR sensor. Melting points (mp) were determined on a Koehler hot stage apparatus and are uncorrected. Commercially available reagents were used without further purification; solvents were dried by standard procedures.

DPPH radical-scavenging activity

DPPH radical-scavenging activity of the samples was assessed by our reported method [43] with minor modifications. The 1,1-diphenyl-2-picrylhydrazyl radical solution was prepared by dissolving an appropriate amount of DPPH in MeOH to give a concentration of 1 mM. The DPPH radical solution (1 mM; 0.5 mL) was added to a solution of the compound to be tested in MeOH (4 mL) to give a final concentration of 0.05 mM. The mixture was allowed to react for 30 min at room temperature before the absorbance was read at 517 nm. The percentage inhibition was calculated as follows: percentage inhibition = ([A0 − A1] / A0) × 100, where A0 is the absorbance of the control and A1 is the absorbance of the sample.

Synthesis of hydrazinyl thiocoumarin derivatives

10g,h from (naphthalen-2-yl)thiosemicabazides

9a,b

The title compound was synthesized by a similar procedure described for the synthesis of 10a-f, using 3-bromoacetyl coumarin (4) with naphthalen-2-yl)thiosemicabazide 9a,b.

(E)-3[2-[2-(1-Naphthylidene)hydrazinyl][thiazol-4-yl]-2H-chromen-2-one (10g)

The title compound (10g) (114 mg, 71%) was obtained after purification by recrystallization, using EtOAc–EtOH (3:1), as a yellow solid, mp 262–264°C (Lit. mp 262–265°C [20]; 240–242°C [15]); IR (KBr) $\nu$ max 3424 (NH), 1702 (O=C = O), 1594 (C = N); 1H NMR (400 MHz, DMSO–d$_6$) δ 12.15 (1H, br s), 8.79 (1H, $J = 8.5$ Hz), 8.71 (1H, s), 8.59 (1H, s), 8.01 (2H, $J = 7.8$ Hz), 7.88 (2H, $J = 7.6$ Hz), 7.83 (1H, s), 7.67 (1H, ddd, $J = 8.1, 7.5, 0.9$ Hz), 7.63 (1H, $J = 8.5$ Hz), 7.62 (2H, ddd, $J = 7.8, 1.8$ Hz), 7.49 (1H, d, $J = 8.1$ Hz), 7.41 (1H, $J = 7.5$ Hz).

(E)-3[2-[2-(2-Hydroxynaphthylidene)hydrazinyl][thiazol-4-yl]-2H-chromen-2-one (10h)

The title compound (10h) (119 mg, 79%) was obtained after purification by recrystallization, using EtOAc–EtOH (2:1), as a brown solid, mp 271–273°C (Lit. mp 272–274°C [20]); IR (KBr) $\nu$ max 3439 (NH), 3207 (NH), 1705 (O=C = O), 1602 (C = N); 1H NMR (400 MHz, DMSO–d$_6$) δ 12.25 (1H, br s), 10.92 (1H, br s), 8.99 (1H, s), 8.78 (1H, d, $J = 8.6$ Hz), 8.59 (1H, d, $J = 8.6$ Hz), 7.68 (1H, ddd, $J = 8.3, 7.5, 1.1$ Hz), 7.50 (1H, d, $J = 8.3$ Hz), 7.44 (1H, d, $J = 7.5$ Hz), 7.38 (1H, ddd, $J = 8.5, 2.5$ Hz), 6.87 (1H, d, $J = 8.5$ Hz).

(E)-3[2-[2-(2-Hydroxy-3-methoxybenzylidene)hydrazinyl][thiazol-4-yl]-2H-chromen-2-one (10i)

The title compound (10i) (132 mg, 77%) was obtained after purification by recrystallization, using EtOAc–EtOH (2:1), as a brown solid, mp 266–267°C (Lit. mp 266–267°C [20]); IR (KBr) $\nu$ max 3445 (NH), 3239 (OH), 1704 (O=C = O), 1600 (C = N); 1H NMR (400 MHz, DMSO–d$_6$) δ 12.18 (1H, br s), 9.45 (1H, br s), 8.56 (1H, s), 8.39 (1H, s), 7.87 (1H, dd, $J = 7.5, 0.9$ Hz), 7.78 (1H, s), 7.62 (1H, ddd, $J = 8.3, 7.5, 0.9$ Hz), 7.46 (1H, $J = 8.3$ Hz), 7.41 (1H, $J = 7.5$ Hz), 7.27 (1H, d, $J = 8.0$ Hz), 6.99 (1H, d, $J = 8.0$ Hz), 6.84 (1H, d, $J = 8.0$ Hz), 3.83 (3H, s).

Synthesis of hydrazinyl thiocoumarin derivatives
at various concentrations (to give a final concentration of DPPH of 0.11 mM). The mixture was shaken vigorously and incubated at room temperature in the dark for 30 min. The decrease in the absorbance of the resulting solution was then measured spectrophotometrically at 517 nm. All measurements were made in triplicate. Two controls were used for this test: a negative control (blank) consisting of MeOH (4 mL) and the DPPH radical solution (0.5 mL) and a positive control comprising the reference anti-oxidant (quercetin or BHT) in MeOH and DPPH radical solution. Inhibition of free radical DPPH in percentage was calculated as follows:

\[
\text{Radical scavenging activity(\%)} = \left(1 - \frac{A_{\text{blank}} - A_{\text{sample}}}{A_{\text{blank}}}\right) \times 100
\]

Where \(A_{\text{blank}}\) is the absorbance of the negative control (containing all reagents except test compounds) and \(A_{\text{sample}}\) is the absorbance of the test compounds and all the reagents. Sample concentration providing 50% inhibition (IC\(50\)) was calculated by plotting the inhibition percentage against sample concentration. All the synthesized compounds were evaluated for DPPH radical scavenging ability and the antioxidant activity of the synthesized compounds was compared with a synthetic antioxidant BHT (butylated hydroxytoluene) and a natural antioxidant quercetin, as the reference standards.

**ABTS\(^+\) radical cation-scavenging activity**

According to a modified method from Arnao et al. [45], a solution of ABTS (7.4 mM) in MeOH and a solution of potassium persulphate (2.6 mM) in MeOH were mixed in equal volumes and allowed to react for 12 hours in the dark at room temperature. The resulting solution (1.0 mL) was diluted (to a volume of 30.0 mL) by the addition of methanol to give an ABTS\(^+\) solution of 0.12 mM and absorbance of 1.1 ± 0.02 at 734 nm. A portion of the ABTS\(^+\) solution (3.0 mL) was added to a methanolic solution (150 µL) of the compound to be tested at various concentrations and the resulting mixture was incubated in the dark for 2 hours. The absorbance of each solution was recorded at 734 nm. All measurements were made in triplicate and for each assay a fresh ABTS\(^+\) stock solution was prepared. Radical scavenging activity was calculated in a similar fashion to the DPPH radical-scavenging assays. The IC\(50\) value of each compound was calculated by plotting the inhibition percentage against concentration of the tested compounds and the results were expressed in \(\mu\)M.

**Competing interests**

The authors declare that they have no competing interests.

**Authors’ contributions**

HO and AA participated in study design and coordination, manuscript preparation and carried out the synthetic experiments, MCB and KCL participated in study design and coordination and manuscript preparation. All authors read and approved the final manuscript.

**Acknowledgements**

This work was supported by the Universiti Sains Malaysia (USM) for a fellowship award to HO, the Universiti Sains Malaysia fellowship for financial support of AA, and grants from the SPARC initiative (award to MCB) and RU grant (1001/PKIMIA/011133) to conduct antioxidant research work (award to AA).
