Abstract

Considering the Generalized Minimal Supergravity Model (GmSUGRA) in the Minimal Supersymmetric Standard Model (MSSM), we study the Electroweak Supersymmetry (EWSUSY), where the squarks and/or gluino are heavy around a few TeVs while the sleptons, sneutrinos, Bino, Winos, and/or Higgsinos are light within one TeV. We resolves the $(g - 2)_\mu/2$ discrepancy for the muon anomalous magnetic moment in the Standard Model (SM) successfully and identifies a parameter space where such solutions also have the electroweak fine-tuning measures $\Delta_{\text{EW}} 16.5$ (6%) and $\Delta_{\text{EW}} 25$ (4%) without and with the WMAP bounds, respectively. We find that the allowed mass ranges, which are consistent within $3\sigma$ of the $g - 2$ discrepancy, for the lightest neutralino, charginos, stau, stau neutrinos, and first two-family sleptons are [44, 390] GeV, [100, 700] GeV, [100, 700], and [52, 700] GeV, respectively. Moreover, our solutions satisfy the latest bounds reported by the ATLAS and CMS Collaborations on electroweakinos and sleptons. The colored sparticles such as light stop, gluinos, and the first two-generation squark masses have been found in the mass ranges of [500, 3000] GeV, [1300, 4300] GeV, and [1800, 4200] GeV, respectively. To obtain the observed dark matter relic density for the Lightest Supersymmetric Particle (LSP) neutralino, we have the bino-wino, LSP neutralino-stau, and LSP neutralino-tau sneutrinos coannihilation scenarios, and the resonance solutions such as A-pole, Higgs-pole, and Z-pole. We identify the higgsino-like LSP neutralino and display its spin-independent and spin-dependent cross sections with nucleons. We present ten benchmark points which can be tested at the up coming collider searches as well.

1 Introduction

It is well-known that supersymmetry (SUSY) provides a natural solution to the gauge hierarchy problem in the Standard Model (SM). In the supersymmetric SMs (SSMs), gauge coupling unification can be realized which strongly indicates the Grand Unified Theories (GUTs), and the electroweak (EW) gauge symmetry can be broken radiatively due to the large top quark Yukawa coupling. If conservation of $R$-parity is assumed, the Lightest Supersymmetric Particle (LSP) such as neutralino is a dark matter candidate. Thus, SUSY is the most promising new physics beyond the SM.

From the first run of the LHC, a SM-like Higgs boson with mass $m_h$ around 125 GeV was discovered in July 2012 [1, 2]. This is a little bit heavy for the Minimal SSM (MSSM) since it requires the multi-TeV top squarks with small mixing or TeV-scale top squarks with large mixing. Moreover, we have strong constraints on the parameter space in the SSMs from the LHC SUSY searches. For example, the gluino mass $m_{\tilde{g}}$ should be heavier than about 1.7 TeV if the first two-generation squark mass $m_{\tilde{q}}$ is around the gluino mass $m_{\tilde{q}} \sim m_{\tilde{g}}$, and heavier than about 1.3 TeV for $m_{\tilde{q}} \gg m_{\tilde{g}}$ [3, 4].

Inspired by the LHC Higgs [5] and SUSY [6] searches, as well as the experimental results/constraints on B physics [7, 8] and Flavour Changing Neutral Current (FCNC) [9, 10, 11], anomalous magnetic momentum of the muon [12, 13], dark matter relic density from WMAP experiment [14], and direct dark matter search from XENON100 experiment [15], one of us (TL) with his collaborators proposed the Electroweak Supersymmetry (EWSUSY), where the squarks and/or gluino are heavy around a few TeVs while the sleptons, sneutrinos, bino, winos, and/or higgsinos are light within one TeV [16]. Especially, the EWSUSY can be realized in the Generalized Minimal Supergravity (GmSUGRA) [17, 18].

In this paper, we shall systematically study the SM $(g - 2)_{\mu}/2$ discrepancy for the muon anomalous magnetic moment in the MSSM with the EWSUSY from GmSUGRA. We find that the EWSUSY from GmSUGRA not only resolves the $(g - 2)_{\mu}/2$ anomaly but also addresses the Electroweak Fine Tuning (EWFT) problem. We show the preferred mass ranges for some SUSY Breaking (SSB) terms required to explain the muon $(g - 2)_{\mu}/2$ anomaly. It is well-known that neutralinos, charginos (collectively known as electroweakinos), and sleptons play very important roles in addressing the muon $(g - 2)_{\mu}/2$ anomaly. We show that the EWSUSY from GmSUGRA very effectively resolves the muon $(g - 2)_{\mu}/2$ anomaly. The allowed mass ranges consistent within $3\sigma$ of $(g - 2)_{\mu}/2$ discrepancy for the LSP neutralino, charginos, stau, stau neutrinos, and first two-family sleptons are $[44, 390]$ GeV, $[100, 700]$ GeV, $[100, 700]$, and $[52, 700]$ GeV, respectively. Recently, the ATLAS and CMS Collaborations have reported new bounds on electroweakinos as well as all three families of sleptons and sneutrinos depending on
various assumptions and topologies. We discuss these bounds in some detail and find that our solutions are consistent with these bounds and still provide resolution to the muon magnetic dipole moment anomaly within $3\sigma$. We also note that some portions the parameter space are not only consistent with all the collider and astrophysical bounds but also provides even within $1\sigma$ contributions to the muon $(g - 2)_\mu/2$ and hence resolves discrepancy successfully. For color sparticles, we note that the light stop is the lightest colored sparticle in our data having mass range $[500, 3000]$ GeV, while gluino mass range is $[1300, 4300]$ GeV. This gluino mass range shrinks a little to 3000 GeV if we insist on dark matter relic density bounds. The first two-family squarks lie in the mass ranges from 1800 GeV to 4200 GeV. We also identify a viable parameter space which satisfies all the bounds including $5\sigma$ WMAP9 bounds, resolves the muon $(g - 2)_\mu/2$ anomaly, as well as provides solutions with small EWFT. We note that in our data the minimal EWFT measures $\Delta_{EW} \sim 16.5$ (6%) and $\Delta_{EW} \sim 25$ (4%) without and with the WMAP9 bound, respectively. In our present scans we find that in order to obtain the observed dark matter relic density, we have the bino-wino, LSP neutralino-stau, LSP neutralino-tau sneutrino coannihilation scenarios and resonance solutions such as $A$-resonance, Higgs-resonance and $Z$-resonance for bino-like neutralino. Moreover, we comment on the bino-like solutions which do not satisfy the WMAP9 bounds. Apart from the bino-like LSP, we have wino-like and higgsino-like LSPs. Such solutions have under abundance relic density. We comment on such wino-like LSP solutions. We display graphs for direct and indirect searches for higgsino-like LSP. Finally we present ten benchmark points in two tables showing some characteristic features of our models.

This paper is organized as follows. In Section 2, we briefly describe the GmSUGRA model and the SSB parameters. We also briefly discuss $(g_\mu - 2)/2$ anomaly and describe our definition of EWFT. In Section 3, we outline the detailed SSB parameters, the ranges of numerical values employed in our scan, the scanning procedure, and the relevant experimental constraints that we have considered. We discuss results of our scans in Section 4. A summary and conclusion are given in Section 5.

2 The EWSUSY from the GmSUGRA in the MSSM

In the GmSUGRA [17, 18], one can realize the EWSUSY, where the sleptons and electroweakinos (charginos, bino, wino, and/or higgsinos) are within one TeV while squarks and/or gluinos can be in several TeV mass ranges [16]. Moreover, the gauge coupling relation and gaugino mass relation at the GUT scale are

$$\frac{1}{\alpha_2} - \frac{1}{\alpha_3} = k \left( \frac{1}{\alpha_1} - \frac{1}{\alpha_3} \right),$$  \hspace{1cm} (1)
\[
\frac{M_2}{\alpha_2} - \frac{M_3}{\alpha_3} = k \left( \frac{M_1}{\alpha_1} - \frac{M_3}{\alpha_3} \right),
\]

where \( k \) is the index and equal to 5/3 in the simple GmSUGRA. We obtain a simple gaugino mass relation

\[
M_2 - M_3 = \frac{5}{3} (M_1 - M_3),
\]

by assuming gauge coupling unification at the GUT scale \((\alpha_1 = \alpha_2 = \alpha_3)\). It is obvious that the universal gaugino mass relation \( M_1 = M_2 = M_3 \) in the mSUGRA, is just a special case of this general one. Choosing \( M_1 \) and \( M_2 \) to be free input parameters, which vary around several hundred GeV for the EWSUSY, we get \( M_3 \) from Eq. (3):

\[
M_3 = \frac{5}{2} M_1 - \frac{3}{2} M_2,
\]

which could be as large as several TeV or as small as several hundred GeV, depending on specific values of \( M_1 \) and \( M_2 \).

The general SSB scalar masses at the GUT scale are given in Ref. [18]. Taking the slepton masses as free parameters, we obtain the following squark masses in the \( SU(5) \) model with an adjoint Higgs field

\[
m_{\tilde{Q}_i}^2 = \frac{5}{6} (m_0 U)^2 + \frac{1}{6} m_{\tilde{E}_c}^2,
\]

\[
m_{\tilde{T}_i}^2 = \frac{5}{3} (m_0 U)^2 - \frac{2}{3} m_{\tilde{E}_c}^2,
\]

\[
m_{\tilde{D}_i}^2 = \frac{5}{3} (m_0 U)^2 - \frac{2}{3} m_{\tilde{L}_i}^2,
\]

where \( m_{\tilde{Q}}, m_{\tilde{U}_c}, m_{\tilde{D}_c}, m_{\tilde{L}}, \) and \( m_{\tilde{E}_c} \) represent the scalar masses of the left-handed squark doublets, right-handed up-type squarks, right-handed down-type squarks, left-handed sleptons, and right-handed sleptons, respectively, while \( m_0 U \) is the universal scalar mass, as in the mSUGRA. In the EWSUSY, \( m_{\tilde{L}} \) and \( m_{\tilde{E}_c} \) are both within 1 TeV, resulting in light sleptons. Especially, in the limit \( m_0 U \gg m_{\tilde{L}/\tilde{E}_c} \), we have the approximated relations for squark masses:

\( 2m_{\tilde{Q}}^2 \sim m_{\tilde{U}_c}^2 \sim m_{\tilde{D}_c}^2 \). In addition, the Higgs soft masses \( m_{\tilde{H}_u} \) and \( m_{\tilde{H}_d} \), and the trilinear soft terms \( A_U, A_D \) and \( A_E \) can all be free parameters from the GmSUGRA [16, 18].

2.1 The anomalous magnetic moment of the muon \( a_\mu = (g - 2)_{\mu}/2 \)

In parallel to the on-going searches for the new physics at the high energy collider, one can look for such effects at low energy. The precise measurement of muon \( a_\mu = (g - 2)_{\mu}/2 \) may reveal, though indirectly, traces for the physics beyond the SM. The SM prediction for the anomalous
magnetic moment of the muon \([12]\) shows a discrepancy with the experimental results \([13]\), which is quantified as follows

\[
\Delta a_\mu \equiv a_\mu(\text{exp}) - a_\mu(\text{SM}) = (28.6 \pm 8.0) \times 10^{-10} .
\]

If SUSY does exist at the EW scale, then the main SUSY contributions to \(a_\mu\) come from the neutralino-smuon and chargino-sneutrino loops and are given as

\[
\Delta a_{\mu}^{\text{SUSY}} \propto \frac{M_i \mu \tan \beta}{m_{\text{SUSY}}^4} ,
\]

where \(M_i (i = 1, 2)\) are the weak scale gaugino masses, \(\mu\) is the higgsino mass parameter, \(\tan \beta \equiv \frac{\langle H_u \rangle}{\langle H_d \rangle}\), and \(m_{\text{SUSY}}\) is the sparticle mass circulating in the loop. It is also evident from Eq. (9) that by having appropriately light \(m_{\text{SUSY}}\) masses (electroweakinos and sleptons), we may have sizeable SUSY contributions to \(\Delta a_\mu\). In order to address the \(g - 2\) anomaly between experiment and theory, new direct measurements of the muon magnetic moment with fourfold improvement in accuracy have been proposed at Fermilab by E989 experiment, and J-PARC \([20]\). First results from E989 are expected around 2017/18. These measurements will firmly establish or constrain new physics effects. Spurred by these developments new studies have been done in order to explore this opportunity \([16, 21]\). In this article while doing general scans we resolve the muon \((g - 2)_\mu/2\) successfully and add new dark matter channels such as Higgs-resonance and Z-resonance consistent with \(\Delta a_\mu\) values within 3\(\sigma\) in addition to the previously reported channels \([16, 22]\). Moreover, we show that our solutions while having previously mentioned properties, also have small electroweak fine-tuning (defined below). In our scans, the sleptons and electroweakinos mass ranges, which are required to address the \((g - 2)_\mu/2\) problem, are in agreement with Refs. \([16, 22, 23]\).

### 2.2 The Electroweak Fine Tuning

It is interesting to note that in addition to resolve \(a_\mu\) anomaly, the EWSUSY from GmSUGRA can also accommodate the solutions with small EWFT. In the first site it appears contradictory. At one hand, from Eq. (9) it appears that the large values of \(\mu\) are required for sizeable \(a_{\mu}^{\text{SUSY}}\) contributions. On the other hand, small EWFT requires small values of \(\mu\). But after looking at Eq. (9) more carefully, we see that by having suitable large values for gaugino masses and \(\tan \beta\), and small values for electroweakino and slepton masses, one can compensate the small values of \(\mu\) (required for small EWFT) and still resolve \(a_\mu\) anomaly.

We use the latest \((7.84)\) version of ISAJET \([24]\) to calculate the fine-tuning (FT) conditions at the EW scale \(M_{\text{EW}}\). After including the one-loop effective potential contributions to the

---

\(^3\)For complete one-loop result, see Ref. \([19]\).
tree-level MSSM Higgs potential, the $Z$-boson mass $M_Z$ is given by

$$M_Z^2 = \frac{(m_{H_d}^2 + \Sigma_d^d) - (m_{H_u}^2 + \Sigma_u^u) \tan^2 \beta}{\tan^2 \beta - 1} - \mu^2,$$

(10)

where $\Sigma_u^u$ and $\Sigma_d^d$ are the contributions coming from the one-loop effective potential defined in Ref. [25] and $\tan \beta \equiv \frac{v_u}{v_d}$. All parameters in Eq. (10) are defined at the $M_{EW}$. In order to measure the EWFT condition we follow [25] and use the following definitions

$$C_{H_d} \equiv |m_{H_d}^2/(\tan^2 \beta - 1)|, \quad C_{H_u} \equiv |-m_{H_u}^2 \tan^2 \beta/(\tan^2 \beta - 1)|, \quad C_\mu \equiv |\mu^2|,$$

(11)

with each $C_{\Sigma_{u,d},d(k)}$ less than some characteristic value of order $M_Z^2$. Here, $k$ labels the SM and SUSY particles that contribute to the one-loop Higgs potential. For the fine-tuning measure we define

$$\Delta_{EW} \equiv \max(C_k)/(M_Z^2/2).$$

(12)

Note that $\Delta_{EW}$ only depends on the weak-scale parameters of the SSMs, and then is fixed by the particle spectra. Hence, it is independent of how the SUSY particle masses arise. Lower values of $\Delta_{EW}$ corresponds to less fine tuning, for example, $\Delta_{EW} = 10$ implies $\Delta_{EW}^{-1} = 10\%$ fine tuning.

3 Phenomenological Constraints and Scanning Procedure

We employ the ISAJET 7.84 package [24] to perform random scans over the parameter space given below. In this package, the weak scale values of the gauge and third generation Yukawa couplings are evolved to $M_{GUT}$ via the MSSM renormalization group equations (RGEs) in the $\overline{DR}$ regularization scheme. We do not strictly enforce the unification condition $g_3 = g_1 = g_2$ at $M_{GUT}$, since a few percent deviation from unification can be assigned to the unknown GUT-scale threshold corrections [26]. With the boundary conditions given at $M_{GUT}$, all the SSB parameters, along with the gauge and Yukawa couplings, are evolved back to the weak scale $M_Z$.

In evaluating Yukawa couplings the SUSY threshold corrections [27] are taken into account at the common scale $M_{SUSY} = \sqrt{m_{\tilde{t}_L}m_{\tilde{t}_R}}$. The entire parameter set is iteratively run between $M_Z$ and $M_{GUT}$ using the full two-loop RGEs until a stable solution is obtained. To better account for the leading-log corrections, one-loop step-beta functions are adopted for gauge and Yukawa couplings, and the SSB parameters $m_i$ are extracted from RGEs at appropriate scales $m_i \equiv m_i(m_i)$. The RGE-improved one-loop effective potential is minimized at an optimized
scale $M_{\text{SUSY}}$, which effectively accounts for the leading two-loop corrections. The full one-loop radiative corrections are incorporated for all sparticles.

The requirement of radiative electroweak symmetry breaking (REWSB) \cite{28} puts an important theoretical constraint on parameter space. Another important constraint comes from limits on the cosmological abundance of stable charged particle \cite{29}. This excludes regions in the parameter space where charged SUSY particles, such as $\tilde{\tau}_1$ or $\tilde{t}_1$, become the LSP. We accept only those solutions for which one of the neutralinos is the LSP.

Using parameters given in Section 2, we have performed the random scans for the following parameter ranges

\begin{align}
100 \text{ GeV} &\leq m_0^U \leq 5000 \text{ GeV}, \\
100 \text{ GeV} &\leq M_1 \leq 900 \text{ GeV}, \\
100 \text{ GeV} &\leq M_2 \leq 800 \text{ GeV}, \\
100 \text{ GeV} &\leq m_{\tilde{L}} \leq 800 \text{ GeV}, \\
100 \text{ GeV} &\leq m_{\tilde{E}^c} \leq 800 \text{ GeV}, \\
100 \text{ GeV} &\leq m_{\tilde{H}^0,u,d} \leq 5000 \text{ GeV}, \\
-6000 \text{ GeV} &\leq A_U = A_D \leq 5000 \text{ GeV}, \\
-5000 \text{ GeV} &\leq A_E \leq 5000 \text{ GeV}, \\
2 &\leq \tan \beta \leq 60. \tag{13}
\end{align}

Also, we consider $\mu > 0$ and use $m_t = 173.3 \text{ GeV}$ \cite{30}. Note that our results are not too sensitive to one or two sigma variation in the value of $m_t$ \cite{31}. We use $m_b^{\overline{\text{DR}}} (M_Z) = 2.83 \text{ GeV}$ as well which is hard-coded into ISAJET. Also note that we will use the notations $A_t, A_b, A_{\tau}$ for $A_U, A_D$ and $A_E$ receptively.

In scanning the parameter space, we employ the Metropolis-Hastings algorithm as described in \cite{32}. The data points collected all satisfy the requirement of REWSB, with the neutralino being the LSP. After collecting the data, we require the following bounds (inspired by the LEP2 experiment) on sparticle masses

\begin{align}
m_{\tilde{t}_1}, m_{\tilde{b}_1} &\gtrsim 100 \text{ GeV}, \tag{14} \\
m_{\tilde{\tau}_1} &\gtrsim 105 \text{ GeV}, \tag{15} \\
m_{\tilde{\chi}^{\pm}_1} &\gtrsim 103 \text{ GeV}. \tag{16}
\end{align}

Moreover, we use the IsaTools package \cite{33, 34} and Ref. \cite{35} to implement the following
B-physics constraints

\[ 0.8 \times 10^{-9} \leq \text{BR}(B_s \rightarrow \mu^+\mu^-) \leq 6.2 \times 10^{-9} \ (2\sigma) \] \ \ [7], \ (17)
\[ 2.99 \times 10^{-4} \leq \text{BR}(b \rightarrow s\gamma) \leq 3.87 \times 10^{-4} \ (2\sigma) \] \ \ [11], \ (18)
\[ 0.15 \leq \frac{\text{BR}(B_u \rightarrow \tau\nu\tau)_{\text{MSSM}}}{\text{BR}(B_u \rightarrow \tau\nu\tau)_{\text{SM}}} \leq 2.41 \ (3\sigma) \] \ \ [10]. \ (19)

In addition to above constraints we impose the following bounds from the LHC and WMAP9 experiments

\[ m_h = 123 - 127 \text{ GeV} \] \ \ [1, 2], \ (20)
\[ m_{\tilde{g}} \gtrsim 1.7 \text{ TeV} \ (\text{for } m_{\tilde{g}} \sim m_{\tilde{\chi}}) \] \ \ [3, 4], \ (21)
\[ m_{\tilde{g}} \gtrsim 1.3 \text{ TeV} \ (\text{for } m_{\tilde{g}} \ll m_{\tilde{\chi}}) \] \ \ [3, 4], \ (22)
\[ 0.0913 \leq \Omega_{\text{CDM}}h^2(\text{WMAP9}) \leq 0.1363 \ (5\sigma) \] \ \ [14], \ (23)
\[ 4.7 \times 10^{-10} \leq \Delta a_\mu \leq 52.7 \times 10^{-10} \ (3\sigma) \] \ \ [13]. \ (24)

4 Numerical Results

4.1 The Preferred Masses Required by \( \Delta a_\mu \)

In this subsection we present results of our scans. In Figs. 1-2 we present graphs of \( \Delta a_\mu \) versus the input parameters given in Section 3. In these plots, grey points satisfy the REWSB and LSP neutralino conditions, aqua points satisfy the mass bounds, B-physics bounds, and \( 123 \text{ GeV} \leq m_h \leq 127 \text{ GeV} \), and red points are subset of aqua points that also satisfy the WMAP9 5\sigma bounds. In Fig. 1, we display graphs in \( M_1 - \Delta a_\mu, M_2 - \Delta a_\mu, M_3 - \Delta a_\mu, A_t(= A_b) - \Delta a_\mu, A_\tau - \Delta a_\mu \), and \( \tan \beta - \Delta a_\mu \) planes. At first we did general scans over the parameter space given by Eq. (13) and then we did the dedicate scans around the phenomenologically interesting solutions. These dedicated searches appear as patches in the graphs. In the top left panel we see that aqua points have \( M_1 \) mass range \([100, 900] \text{ GeV}\) which also have 3\sigma to 1\sigma contributions to \( \Delta a_\mu \). There is a lack of grey points between \( 800 \text{ GeV} \lesssim M_1 \lesssim 900 \text{ GeV} \). It is because initially we generated data up to \( M_1 = 800 \text{ GeV} \). In order to get the light CP-even Higgs boson mass around 125 GeV, we then did some dedicated searches where we had to increase upper ranges of a couple of input parameters. This is the reason why one can see the sharp cut in grey points in this plot and the plot for \( A_t(= A_b) - \Delta a_\mu \) plane. Another point to be noted is that we do not see any preferred range of \( M_1 \) to have large contribution to \( \Delta a_\mu \). Apparently, there are more points between \( 400 \text{ GeV} \lesssim M_1 \lesssim 800 \text{ GeV} \) where we see large values for \( \Delta a_\mu \). But
Figure 1: Plots in $M_1 - \Delta a_\mu$, $M_2 - \Delta a_\mu$, $M_3 - \Delta a_\mu$, $A_t (= A_b) - \Delta a_\mu$, $A_\tau - \Delta a_\mu$ and $\tan \beta - \Delta a_\mu$. Grey points satisfy the REWSB and LSP neutralino conditions. Aqua points satisfy the mass bounds, B-physics bounds and $123 \text{ GeV} \leq m_h \leq 127 \text{ GeV}$. Red points are subset of aqua points that also satisfy the WMAP9 $5\sigma$ bounds. The horizontal black solid lines represent $3\sigma$ $\Delta a_\mu$ values and the dashed purple lines show the central value of $\Delta a_\mu$. 
in fact by generating more data it can be shown that we have more or less same contributions to $\Delta a_\mu$ for all values of $M_1$ between $[100, 900]$ GeV. Since our parameter space is very large so doing these kind of scans is a very time consuming job. But the main purpose of this study is to show that the EWSUSY from GmSUGRA can resolve the apparent discrepancy of muon $\Delta a_\mu$, which is clearly displayed. Moreover, we find that even red points can have any value of $M_1$ between $[100, 900]$ GeV. We note that red points with small $M_1$ values ($M_1 \lesssim 150$ GeV) with $2\sigma$ contributions to $\Delta a_\mu$ represent resonance solutions like Z-pole and Higgs-pole. We will discuss such solution in Section 4.4. We also see that in our present data with $M_1 \sim 500$ GeV, red points have contributions to $\Delta a_\mu$ within $1\sigma$. In the top right panel, we note that aqua points can have $M_2$ values between 140-800 GeV and within $3\sigma$ bounds of $\Delta a_\mu$. The small values of $M_2$ indicate the presence of light wino-type LSP neutralino. On the other hand, the minimal and maximal $M_2$ values for red points are around 250 GeV and 800 GeV, respectively.

In the middle left panel we display values for $M_3$ which we calculate using Eq. (4). Here one can see that we have solutions with both $M_3 < 0$ and $M_3 > 0$. In order to have $3\sigma$ or better $\Delta a_\mu$ contributions and remain consistent with the constraints discussed in Section 3, we need in both cases $|M_3| > 500$ GeV and which indicates relatively heavy gluino. The right middle panel depicts that in our model we need $|A_t| = |A_b| > 3000$ GeV to provide the sizeable SUSY contribution to $\Delta a_\mu$ and consistent with the bounds given in Section 3. These relatively large values of $|A_t|$ will also help to get Higgs boson mass around 125 GeV. In the left bottom panel we observe that aqua solutions have $A_\tau$ range anywhere between $-800$ GeV $\lesssim A_\tau \lesssim 800$ GeV. But for red points we have $-600$ GeV $\lesssim A_\tau \lesssim 800$ GeV. The bottom right panel shows range for $\tan \beta$ consistent with $3\sigma$ bounds of $\Delta a_\mu$. We see that the contributions to $\Delta a_\mu$ increase as $\tan \beta$ increases, which can be understood from Eq. (9). For $\tan \beta \approx 12-60$ and 20-25 respectively for aqua and red points, we have solutions within $1\sigma$ ($20.7 \times 10^{-10} - 36.7 \times 10^{-10}$) bounds on $\Delta a_\mu$. We also note large $\Delta a_\mu$ contributions for $40 \lesssim \tan \beta \lesssim 60$ for aqua points.

In Fig. 2 we show plots in $m_0^U - \Delta a_\mu$, $m_{E^c} - \Delta a_\mu$, $m_{\tilde{L}} - \Delta a_\mu$, $m_{\tilde{Q}} - \Delta a_\mu$, $m_{\tilde{U}_c} - \Delta a_\mu$, and $m_{\tilde{D}_c} - \Delta a_\mu$ planes. The colour coding is the same as in Fig. 1. In top left panel we see that $m_0^U$ is any where between 100-3600 GeV if we consider aqua points but for red point it is restricted to be around 3000 GeV. In the right top panel we observe that aqua points within $3-2\sigma$ bounds on $\Delta a_\mu$ have $m_{E^c}$ from 100 to 800 GeV. Similarly, red points share the same mass range. The middle left plot shows the mass range $[130, 800]$ GeV for the universal left-handed sleptons $\tilde{L}$. Like the right-handed sleptons $\tilde{E}^c$, $\tilde{L}$ more or less share the same mass range for both aqua and red points. In the right middle, bottom left and bottom right panels we display masses for left-handed, right-handed up-type and down-type squarks, respectively, which we calculate by using Eq. (7). For the left-handed squarks we have slightly narrow allowed mass ranges as
compared to the right-handed squarks. Also, $\tilde{U}^c$ and $\tilde{D}^c$ have almost the same mass ranges, which are consistent with Eq. (7).

Figure 2: Plots in $m_U^\nu - \Delta a_\mu$, $m_E - \Delta a_\mu$, $m_L - \Delta a_\mu$, $m_Q - \Delta a_\mu$, $m_U - \Delta a_\mu$ and $m_D - \Delta a_\mu$ planes. The color coding is the same as in Fig. 1.
4.2 Compatibility Between the $\Delta a_\mu$ Bound and EWFT

Fig. 3 displays plots in $m_h - \Delta a_\mu$ and $\Delta_{EW} - \Delta a_\mu$ planes. The color coding is the same as in Fig. 1 except that in $m_h - \Delta a_\mu$ plane we do not apply Higgs mass bound. The left panel shows plenty of solutions accommodating bounds on Higgs boson mass 123-127 GeV, having sizeable contributions to $\Delta a_\mu$, and being consistent with the sparticle mass bounds and B-physics bounds mentioned in Section 3. Red points are mostly concentrated in the Higgs boson mass range $123 \text{ GeV} \lesssim m_h \lesssim 124 \text{ GeV}$ and have $\Delta a_\mu$ contributions within 2σ. In the left panel, we find that aqua and red points have small values for fine-tuning measure $\Delta_{EW}$. These points not only resolve $\Delta a_\mu$ discrepancy but also provide solution to the EWFT problem. As we mentioned earlier, this can be understood from Eq. (9), where we see that the SUSY contribution to $\Delta a_\mu$ is proportional to $\mu$, gaugino masses ($M_{1,2}$) and $\tan \beta$, but inversely proportional to the fourth power of $m_{SUSY}$ (the mass scale related to charginos, smuons, sneutrino, and neutralinos). Small EWFT requires small values of $\mu$, while sizeable $\Delta a_\mu$ contributions have opposite requirement for $\mu$. But if the gaugino masses and $\tan \beta$ are appropriately large (as can be seen in Figs. 1) and $m_{SUSY}$ is small (as can be seen below in Fig. 4), one can indeed have sizable $\Delta a_\mu$. In our data the minimal value of $\Delta_{EW}$ is about 16.5 (6%) with $\Delta a_\mu \approx 11.6 \times 10^{-10}$ for aqua points and for red points $\Delta_{EW}$ can be as small as 25 (4%) with $\Delta a_\mu \approx 15.1 \times 10^{-10}$.

![Figure 3](image_url)  
**Figure 3**: Plots in $m_h - \Delta a_\mu$ and $\Delta_{EW} - \Delta a_\mu$ planes. The color coding is the same as in Fig. 1 except that in $m_h - \Delta a_\mu$ plane we do not apply the Higgs boson mass bound.

4.3 Supersymmetry Searches at the LHC

The viable parameter space in the SSMs is still large, so efforts are going on to find its evidence(s). If $R$-parity is conserved, SUSY particles are pair produced, and the lightest neutralino in most of the cases is the LSP and thus dark matter candidate. Charginos ($\tilde{\chi}_{1,2}^{\pm}$)
Figure 4: Plots in $m_{\tilde{\chi}^\pm} - m_{\tilde{\chi}^0}$, $m_{\tilde{\tau}} - m_{\tilde{\chi}^0}$, $m_{\tilde{\nu}} - m_{\tilde{\chi}^0}$, $m_{\tilde{\tau}} / m_{\tilde{\chi}^0} - m_{\tilde{\chi}^\pm}$, $m_{\tilde{\nu}} / m_{\tilde{\chi}^0} - m_{\tilde{\chi}^\pm}$, and $m_{\tilde{\tau}} - m_{\tilde{\chi}^\pm}$ planes. Blue points represent the bino-type LSP neutralino and satisfy REWSB. They are consistent with bounds on sparticle and Higgs boson masses including $123 \text{ GeV} \leq m_h \leq 127 \text{ GeV}$, B-physics, and $4.7 \times 10^{-10} \lesssim \Delta a_\mu \lesssim 52.7 \times 10^{-10}$. Red points are subset of blue points which satisfy the WMAP9 5$\sigma$ bound.
and neutralinos ($\tilde{\chi}^0_{1,2,3,4}$) can decay into leptonic final states via superpartners of neutrinos ($\tilde{\nu}$, sneutrinos) or charged leptons ($\tilde{l}$, sleptons), or via $W$, $Z$ or Higgs ($h$) bosons ($\tilde{\chi}^\pm \rightarrow \ell^\pm \tilde{\nu}, \nu \ell^\mp, W^\pm \tilde{\chi}^0_j, Z \tilde{\chi}^\pm_j, h \tilde{\chi}^0_j$, and $\tilde{\chi}^0_1 \rightarrow \nu \tilde{\nu}, \ell^\pm \tilde{\ell}^\mp, W^\pm \tilde{\chi}^0_1, Z \tilde{\chi}^0_1, h \tilde{\chi}^0_1$, respectively). In recent studies the ATLAS and CMS Collaborations have reported new bounds on electroweakinos. For example in Ref. [36], direct production of charginos and neutralinos is presented in events with three leptons and missing transverse energy $E_T^{miss}$ for 8 TeV center-of-mass energy. Here the simplified models are employed to study the direct pair production of $\tilde{\chi}^\pm_1$ and $\tilde{\chi}^0_2$. In the scenario in which the masses of sleptons and sneutrinos lie between $\tilde{\chi}^0_2$ is assumed to be pure bino. In the scenario in which slepton $\tilde{\chi}^0_1$ and $\tilde{\chi}^0_2$ decay via the first-two generation sleptons and sneutrinos $\tilde{l}/\tilde{\nu}$, their masses can be excluded up to 700 GeV. On the other hand if only $\tilde{\tau}/\tilde{\nu}_\tau$ as the next to the LSP (NLSP) are involved while the first two-generation sleptons/sneutrinos are heavy, then the lower mass limit for $\tilde{\chi}^0_1$ and $\tilde{\chi}^0_2$ is 380 GeV. In case of $W/Z$ and $W/h$ mediated decays, $\tilde{\chi}^+_1$ and $\tilde{\chi}^0_2$ mass limits are 345 GeV and 148 GeV respectively. In another ATLAS SUSY searches [37], the direct productions of charginos, neutralinos, and sleptons in the final states with two leptons and missing transverse energy at 8 TeV center-of-mass energy is reported. Here too, $\tilde{\chi}^+_1$ and $\tilde{\chi}^0_2$ are assumed to be degenerate and pure winos while $\tilde{\chi}^0_1$ is pure bino. In the scenario in which the masses of sleptons and sneutrinos lie between $\tilde{\chi}^\pm_1$ and $\tilde{\chi}^0_1$, $\tilde{\chi}^+_1$ decays promptly to $l\nu\tilde{\chi}^0_1$ via $\tilde{l}\nu$ or $l^\pm\tilde{\nu}$, and its mass can be excluded in the range $[140, 465]$ GeV. On the other hand, if $\tilde{\chi}^+_1$ is the NLSP and decays via $W$ to $l\nu\tilde{\chi}^0_1$, its mass is excluded in the ranges $[100, 105]$ GeV, $[120, 135]$ GeV, and $[145, 160]$ GeV. Another scenario in which $\tilde{\chi}^+_1$ and $\tilde{\chi}^0_2$ considered mass degenerate and the NLSPs, the direct $\tilde{\chi}^+_1\tilde{\chi}^0_2$ production is followed by the decays $\tilde{\chi}^+_1 \rightarrow W^\pm \tilde{\chi}^0_1$ and $\tilde{\chi}^0_2 \rightarrow Z \tilde{\chi}^0_1$ with a 100% branching fraction. In this case the excluded mass range for $\tilde{\chi}^+_1$ and $\tilde{\chi}^0_2$ is $[180, 335]$ GeV. A scenario in which slepton $\tilde{l}$ is the NLSP ($pp \rightarrow \tilde{l}^+\tilde{l}^- \rightarrow l^\pm\tilde{\chi}^0_1$), the common values of the left- and right-handed selectron and smuons masses between 90 GeV and 325 GeV are excluded, and for $m_{\tilde{\chi}^0_1}$ = 100 GeV the common values of the left- and right-handed selectron and smuons masses between 160 GeV and 310 GeV are excluded. Similar studies have also been reported by the CMS Collaboration [38]. In the light of these results, we investigate our data in Fig. 4. The color coding for this figure is the following. Blue points represent the bino-type LSP neutralino, satisfy REWSB, and are consistent with the bounds on sparticle/Higgs masses including 123 GeV $\leq m_h \leq 127$ GeV, B-physics, and $4.7 \times 10^{-10} \lesssim \Delta a_\mu \lesssim 52.7 \times 10^{-10}$. Red points are subset of blue points that satisfy the WMAP9 5$\sigma$ bounds. The black solid lines are just to guide the eyes where we expect mass degeneracy in LSP neutralino and other sparticle masses. We present plot in $m_{\tilde{\chi}^+_1} - m_{\tilde{\chi}^0_1}$ plane in the left top panel. Here blue and red points along the line represent the bino-wino

\[3^4\text{In the results given below, } m_{\tilde{\chi}^0_1} = 0 \text{ is assumed unless stated otherwise.} \]
coannihilation solutions. The chargino mass ranges for these points are $[140, 410]$ GeV and $\sim [180, 410]$ GeV for blue and red points, respectively. Interestingly, these red solutions are consistent with the bounds on the NLSP $\tilde{\chi}_1^\pm$ mentioned above. There is a horizontal strip of points along $m_{\tilde{\chi}_1^0} \approx 45$ GeV, which are the Z-pole solutions. We also have another horizontal strip of red points around $m_{\tilde{\chi}_1^+} \sim 430$ GeV and $m_{\tilde{\chi}_1^0} \sim 60$ GeV which represents Higgs-pole solutions. The above mentioned bounds on charginos do not apply on the resonance solutions. We will discuss these solutions later on. We also find blue and red points with $m_{\tilde{\chi}_1^0} \gtrsim 150$ GeV and $100$ GeV $\lesssim m_{\tilde{\chi}_1^+} \lesssim 700$ GeV. These are the points where the NLSPs are sleptons or sneutrinos (either the first two generations or third generation). We have to be careful about all of these points and check their status. For this purpose, we display plots in $m_{\tilde{\tau}_1} - m_{\tilde{\chi}_1^0}$ and $m_{\tilde{\nu}_\tau} - m_{\tilde{\chi}_1^0}$ planes. In these plots, there are points where stau and tau sneutrino are the NLSPs and are degenerate in mass with the LSP neutralino. In order to make sure whether these NLSP solutions satisfy the bounds on charginos discussed above, we present plots in $m_{\tilde{\tau}_1}/m_{\tilde{\chi}_1^0} - m_{\tilde{\chi}_1^0}$ and $m_{\tilde{\nu}_\tau}/m_{\tilde{\chi}_1^0} - m_{\tilde{\chi}_1^0}$ planes. These plots clearly show that all the points $m_{\tilde{\chi}_1^+} \gtrsim 380$ GeV are allowed as they satisfy the chargino mass bounds in case of $\tilde{\tau}/\tilde{\nu}_{\tau}$-mediated chargino decays given above. In the bottom left panel, we display plot in $m_{\tilde{l}} - m_{\tilde{\chi}_1^0}$ plane, which shows that most of our solutions easily satisfy the upper bounds on the first-two generation slepton masses $325$ GeV and $310$ GeV respectively for $m_{\tilde{\chi}_1^0} = 0$ and $150$ GeV.

Figure 5: Plots in $M_3 - m_{\tilde{U}_0}^U$ and $m_{\tilde{g}} - m_{\tilde{u}_l}$ planes. Grey points satisfy the REWSB and the lightest neutralino as an LSP conditions. Aqua points satisfy the sparticle mass bounds, B-physics bounds, and $123$ GeV $\leq m_h \leq 127$ GeV. Orange points form a subset of aqua points which satisfy the $3\sigma$ bounds on $\Delta a_\mu$. Red points are subset of orange points that also satisfy the WMAP9 $5\sigma$ bounds. Also, we do not apply the squark and gluino mass bounds on the right panel, which are $1.8$ TeV and $1.3$ TeV, respectively.

In Fig. 5, we present plots in $M_3 - m_{\tilde{U}_0}^U$ and $m_{\tilde{g}} - m_{\tilde{u}_l}$ planes. Grey points satisfy the REWSB and neutralino as an LSP conditions. Aqua points satisfy the mass bounds, B-physics bounds,
and } 123 \text{ GeV} \leq m_h \leq 127 \text{ GeV}. \text{ Orange points form a subset of aqua points that satisfy the } 3 \sigma \text{ bounds on } \Delta a_\mu. \text{ Red points are subset of orange points which also satisfy WMAP9 } 5 \sigma \text{ bounds. In the left panel orange points can be divided in three portions. In case of large } M_3 \text{ and large } m_0^U, \text{ all colored sparticles are decoupled with masses around several TeV. For large } M_3 \text{ and small } m_0^U, \text{ the colored sparticle spectra will be similar. However, when } M_3 \text{ is small but } m_0^U \text{ is large, gluino is light around or below 1 TeV, while squarks are heavy. The mass}^2 \text{ of the right-handed squarks is predicted to be approximately twice of the left-handed ones. In the right panel, we show the mass ranges for gluino and left-handed squarks in our scans and do not apply squark and gluino mass bounds here. The black horizontal and vertical lines represent the squark and gluino bounds. For orange points the gluino mass range is about } \sim [1300, 4300] \text{ GeV corresponding to squark mass range } \sim [1800, 4000] \text{ GeV. While for red points, the upper limits on gluino and squark masses are relatively light about 3400 GeV. Here we also note that because we have relatively light gluinos compared to } m_{\tilde{g}} \gtrsim 2 \text{ TeV reported in Refs. [16, 22], our parameter space can be probed easily at the next round of LHC supersymmetry searches. It is shown in Ref. [39] that the squarks and gluino with masses around 2.5 \text{ TeV, 3 TeV, and } 6 \text{ TeV may be probed by the LHC14, High Luminosity (HL) LHC14, and High Energy (HE) LHC33, respectively. This clearly shows that our models have testable predictions. Moreover, if we have collider facility with even higher energy in the future, we will be able to probe even larger values of sparticle masses.}

\subsection*{4.4 Dark Matter Relic Density}

In this subsection we discuss the possible mechanism through which in our present scans, we get the observed dark matter relic density, and also satisfy all the phenomenological bounds such as sparticle mass bounds, the Higgs boson mass bounds, 3\sigma bounds on } \Delta a_\mu, \text{ and B-physics bounds. We have already shown the existence of bino-wino coannihilation scenario in our model in the top left panel of Fig. 4. Just to remind the reader, red points in that figure statisfy satisfy all the bounds just mentioned above. We see red points along the black line with chargino mass 170-410 \text{ GeV. Some portions of this mass range have already been explored by the LHC searches as discussed above. The International Linear Collider (ILC), a proposed } e^+e^- \text{ collider [40, 41] was designed to operate at center-of-mass energy } \sqrt{s} \sim 0.25-1 \text{ TeV. At the ILC one can probe chargino mass up to } \sqrt{s}/2. \text{ This clearly shows that the entire chargino mass range mentioned above can be tested at the ILC, and we can have valuable information about SUSY contributions to } g-2 \text{ indirectly. Moreover, in the same plot we can see the Z-pole solutions with } m_{\tilde{\chi}_1^0} \sim 45 \text{ GeV. Such solutions are constrained by the Z-invisible decay width (}\Gamma \sim 0.2\text{) to dark mater pair [42]. It was shown in Ref. [43] that this decay width can be translated}
for bino-LSP case in terms of $\mu$ and $\mu \gtrsim 140$ GeV is required in order to avoid experimental bound. We have checked that all of our red points satisfy this bound.

In the same plane, there exist the Higgs-resonance solutions as a horizontal strip of red points around $m_{\tilde{\chi}_1^0} \sim 60$ GeV. We show Point 1 in Table 2 as an example of such solutions. In particular, note that $Br(higgs \rightarrow \tilde{\chi}_1^0\tilde{\chi}_1^0) \sim 4.68 \times 10^{-4}$, it is consistent with the results reported in Ref. [44]. In the top right and middle left panels of Fig. 4, it is easy to see that we can accommodate the LSP neutralino-stau and LSP neutralino-tau sneutrino coannihilation scenarios. The middle right and bottom left panels of Fig. 4 show that in these scenarios, solutions with $\tilde{\chi}_1^\pm \gtrsim 380$ GeV do survive. Because the production cross-section of $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ is very large as compared to sleptons, it will be very hard to probe such solutions at the LHC. Apart from Higgs-pole and $Z$-pole solutions we also have $A$-resonance solutions as can be seen in Fig. 6. The color coding is the same as in Fig. 4, and the black line there represents $m_A = 2m_{\tilde{\chi}_1^0}$. For blue points, we have $m_A$ as light as 370 GeV and as heavy as 700 GeV along the line. While for red points, the lower limit for $m_A$ is about 600 GeV. Apart from our red points that satisfy the 5$\sigma$ WMAP9 bound in Figs. 4 and 6, we would like to comment on blue points. These blue solutions have $\Omega h^2$ values either above or below the 5$\sigma$ WMAP9 bounds. To solve this problem, in the former case, one can treat bino as the NLSP and assume that it decays to a lighter state, for example, $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{a}$ where $\tilde{a}$ is axino. In such a scenario we will have the mixed axion and axino ($a\tilde{a}$) dark matter [45]. In the latter case where we have relic density $\Omega h^2 \sim 10^{-5} - 10^{-2}$, the neutralino abundance can be accommodate in the Pecci-Quinn augmented MSSM, where $m_{\tilde{a}} > m_{\tilde{\chi}_1^0}$ and additional neutralinos are produced via thermal axino production and decay $m_{\tilde{a}} \rightarrow m_{\tilde{\chi}_1^0}\gamma$ [46]. In these cases, the cold dark matter tends to be neutralino dominant with a small component of axions. In addition to the bino-type neutralino LSP, we have the wino-type and higgsino-type neutralino LSPs as well. Let us discuss them one by one. It was shown in
Refs. [47, 48] that for NFW and Einasto distributions, the entire mass range of thermal wino dark matter from 0.1 to 3 TeV may be excluded. In a recent study [49], it was shown that wino as dark matter candidate is excluded in the mass range below 800 GeV from antiproton and between 1.8 TeV to 3.5 TeV from the absence of a γ-ray line feature toward the galactic center. Because our wino-type solutions have very small relic density from $10^{-3}$ to $10^{-5}$, for example, Point 5 in Table 1, the light wino like LSP neutralino, which can provide a solution to the $a_\mu$ anomaly, does satisfy the above constraints. Even if one has a thermal wino-like LSP neutralino with mass around 2.8 TeV and the observed relic density, one can escape the above bounds by assuming that the wino-like neutralino is the NLSP and decays to axino and γ. Another example of solutions with under abundance relic density is the higgsino-like LSP. In order to match the observed dark matter relic density, we need an additional dark matter candidate along with higgsino. In this scenario the higgsino could make only a small fraction of the dark matter relic density and the remaining abundance is composed of axinos produced through the vacuum misalignment [50]. This also provides the possibility to detect axinos along with the chances to detect higgsinos despite the fact that their relic density is somewhat suppressed between 1-15 in the present Universe. In the top left panel of Fig. 7 we plot the rescaled higgsino-like neutralino spin-independent cross section $\xi \sigma^{SI}(\tilde{\chi}_1^0 p)$ versus $m($higgsino$)$. The orange solid line represents the current upper bound set by the CDMS experiment, and the black solid line depicts the upper bound set by XENON100 experiment [15], while the purpl, orange, and black dashed lines represent respectively the future reach of the LUX [51], SuperCDMS [52] and XENON1T [53] experiments respectively. In order to account for the fact that the local higgsino relic density might be much less than the usually assumed value $\rho_{\text{local}} \simeq 0.3 \text{GeV/cm}^3$, we rescale our results by a factor $\xi = \Omega_{\tilde{\chi}_1^0} h^2 / 0.11$ [54]. Blue points satisfy all the bounds mentioned in Section 3 except the WMAP9 bounds. We note that these solutions have $50 \lesssim \Delta_{EW} \lesssim 130$ and most of the solutions have $\Delta_{EW} \lesssim 100$. However, the solutions with $m($higgsino$)$ in the range [200, 300] GeV have already ruled out by the XENON100 experiment, and the rest of the solutions will be probed by the LUX, SuperCDMS and XENON1T experiments but not completely. Here we would like to comment on our solution just below the XENON1T reach line with higgsino mass around $m($higgsino$) \sim 200$ GeV which has $\mu \sim 209$ GeV and $\Delta_{EW} \sim 102$. The presence of this point shows that it would be difficult to rule out the higgsino-like LSP neutralino for entire parameter space in $R$-parity conserving natural SUSY models [55]. The top right panel shows a plot in the rescaled higgsino-like neutralino spin-dependent cross section $\xi \sigma^{SD}(\tilde{\chi}_1^0 p)$ as a function of $m($higgsino$)$. Green line represents the upper bound set by COUPP experiment [56]. We see that our solutions are about a couple of magnitude below the current bounds from the COUPP experiment. For comparison, in the bottom panel of Fig. 7, we present a plot of the (non-
rescaled) higgsino-like neutralino spin-dependent cross section $\sigma_{SD}(\tilde{\chi}_0^0 p)$ versus $m($higgsino$)$. The IceCube DeepCore and future IceCube DeepCore bounds are shown in black solid line and black dashed line [57]. The color coding is the same as the left panel. Because the IceCube detection depends on whether the Sun has equilibrated its core abundance between capture rate and annihilation rate [58], we do not rescale our results here. It was shown in [59] that for the Sun, equilibration is reached for almost all of SUSY parameter space. If this is true, then our solutions will be probed by the future IceCube DeepCore experiment. However, we are not sure whether such equilibration can be reached if the SUSY particles are relatively heavy.

In Table 1, we present five benchmark points. All the points satisfy the bounds on the sparticle and Higgs boson masses as well as the constraints from B-physics and $\Delta a_\mu$ described in Section 3. Points 1 and 2 are the solutions with the minimal values of $\Delta_{EW}$ that are respectively not consistent and consistent with the WMAP9 5$\sigma$ bound. Here we see that the mass of the bino-like LSP neutralino is about $\sim 46$-48 GeV, $m_{\tilde{\chi}_1^\pm}$ range is $\sim [165, 211]$ GeV while the CP-even Higgs boson mass is around 123 GeV. For the first two-family sleptons and sneutrinos, the left-handed sleptons are lighter than the right-handed sleptons and are in the mass range $[380, 460]$ GeV, while the third-family light stau and tau sneutrino can be as light as 266 GeV and 240 GeV, respectively. For the colored sparticles, gluino mass is around 1800 GeV, the first-two family squarks are in the mass range $\sim [2000, 2400]$ GeV, and light stop is around 830 GeV. Point 2 also represents the Z-pole solutions. Point 3 represents a solution with large contribution to $\Delta a_\mu \sim 22.4 \times 10^{-10}$ (within one $\sigma$ bound on $\Delta a_\mu$) and consistent with the 5$\sigma$ WMAP9 bounds. It is also an example of the bino-wino coannihilation scenario with $m_{\tilde{\chi}_1^0} \sim 218$ GeV and $m_{\tilde{\chi}_1^\pm} \sim 234$ GeV. Here, we see that the Higgs boson mass is around 124 GeV, the first two-family left- and right-handed sleptons respectively have masses $\sim 251$ GeV and 552 GeV, the light stau mass is around 247 GeV, and the tau sneutrino mass is 287 GeV. Gluino mass is around 2000 GeV, while the first two-family squark masses are from 2680 to 3430 GeV. The light stop mass is around 1444 GeV. Points 4 and 5 respectively are the examples of solutions with large gluino masses about 3323 GeV and 4215 GeV and 125 GeV light CP-even Higgs boson mass. Point 4 is consistent with relic density bounds with $\Delta a_\mu \sim 7.87 \times 10^{-10}$, while Point 5 have $\Delta a_\mu \sim 11.54 \times 10^{-10}$ but do not satisfy relic density bound. Point 4 is another example of the bino-wino coannihilation scenario. Point 5 is the representative of the wino-like LSP neutralino solutions. For Points 4 and 5, the first two-family right-handed sleptons are respectively 943 GeV and 870 GeV, but the corresponding left-handed sleptons are 504 GeV and 477 GeV. Also, sneutrinos have masses 497 GeV and 430 GeV, respectively. The light stau and tau sneutrino masses for Point 4 are 457 GeV and 502 GeV while for Point 5 light stau mass is 136 GeV and tau sneutrino mass is about 283 GeV.
Figure 7: In the top left panel rescaled higgsino-like neutralino spin-independent cross section $\xi\sigma^{SI}(\tilde{\chi}^0_1 p)$ versus $m_{\text{higgsino}}$ is shown. Orange solid line represents the current upper bound set by the CDMS experiment and black solid line depicts the upper bound set by XENON100, while the purple, orange and black dashed lines represent respectively the future reach of the LUX, SuperCDMS and XENON1T experiments. The top right panel shows plot in rescaled higgsino-like neutralino spin-dependent cross section $\xi\sigma^{SD}(\tilde{\chi}^0_1 p) - m_{\text{higgsino}}$ plane. Green line represents the upper bound set by COUPP experiment. In the bottom panel (non-rescaled) higgsino-like neutralino spin-dependent cross section $\sigma^{SD}(\tilde{\chi}^0_1 p)$ versus $m_{\text{higgsino}}$ is displayed. The IceCube DeepCore (black solid line) bound is shown and future IceCube DeepCore bound is depicted by the black dashed line. Color coding is same as in Fig. 4.
In Table 2, we display another five benchmark points consistent with the constraints described in Section 3. Points 1, 2, 3, and 4 represent Higgs-resonance, A-resonance, neutralino-stau and neutralino-tau sneutrino solutions, respectively. Point 5 is an example of the higgsino-like LSP. Here we see that all of these points have a lot of common features. Gluino masses are in the range [1700, 2100] GeV while the first two-family squarks have masses from around 2700 GeV to 3600 GeV. The light stop mass lies in the range [1000, 1750] GeV. Also, the first two-family sleptons and sneutrinos are almost degenerate. In both tables of benchmark points the light stop is the lightest colored sparticle. Point 5 has the rescaled higgsino-like neutralino spin-independent cross section \(\xi \sigma_{SI}(\tilde{\chi}_1^0 p) = \Omega_{\tilde{\chi}_1^0} h^2 / 0.11 \times \sigma_{SI}(\tilde{\chi}_1^0 p) \sim 2.09 \times 10^{-11} \text{pb}\), which is below the XENON1T experimental low bound.

## 5 Discussions and Conclusion

We attempted to resolve the muon \((g - 2)_\mu/2\) discrepancy in the SM by exploring the MSSM with the EWSUSY from GmSUGRA. We identified a viable parameter space that resolves this discrepancy, and as a by product we obtained the solutions with small EWFT simultaneously. Our solutions not only provide sizable contributions to \(\Delta a_\mu\) but also satisfy all the current experimental constraints including the LHC SUSY searches. In particular, the relic density for cold dark matter can be achieved within the 5\(\sigma\) WMAP9 bounds by the bin-wino, neutralino-stau, neutralino-tau sneutrino coannihilation scenarios, and the \(A\), Higgs and \(Z\) resonance scenarios. Moreover, we identified the higgsino-like LSP neutralino and calculate the spin-independent and spin-dependent cross sections on the LSP neutralinos with nucleons.

Table 1: All the masses in this table are in units of GeV. All the points satisfy the constraints described in Section 3. Points 1 and 2 display the solutions with the minimal values of $\Delta_{EW}$ which are respectively not consistent and consistent with the 5$\sigma$ WMAP9 bounds. Point 2 is an example of Z-pole solutions. Point 3 represents a solution with large contribution to $\Delta a_\mu$ and consistent with the 5$\sigma$ WMAP9 bounds. Point 4 and 5 are the examples with large gluino masses, 125 GeV light CP-even Higgs boson mass, which are respectively consistent and not consistent with the 5$\sigma$ WMAP9 bounds. Points 3 and 4 are the bino-wino coannihilation scenario while Point 5 represents wino-like LSP solutions.

Table 2: All the masses in this table are in units of GeV. All points satisfy all the constraints in Section 3 except point 4 which does not satisfy the 5$\sigma$ WMAP9 bounds. Points 1, 2, 3, and 4 represent the Higgs-resonance, $A$-resonance, neutralino-stau coannihilation, and neutralino-stau neutrino coannihilation solutions, respectively. Point 5 is an example of the higgsino-like LSP. This point has the rescaled higgsino-like neutralino spin-independent cross section $\xi \sigma_{SI}(\tilde{Z}_1p)$ below the XENON1T experimental upper bound ($\Omega_{\tilde{\chi}_1^0 h^2}/0.11 \times \sigma_{SI}(\tilde{\chi}_1^0 p) \sim 2.09 \times 10^{-11}$pb).
