Innate immunity receptors play a critical role in host defence, as well as in allergy and asthma. The aim of this exploratory study was to evaluate whether there are associations between TLR7 rs179008, TLR8 rs2407992, TLR9 rs187084 or TLR10 rs4129009 polymorphisms and viral findings, clinical characteristics or subsequent wheezing in infants with bronchiolitis. In all, 135 full-term infants were hospitalized for bronchiolitis at age less than 6 months: 129 of them were followed-up until the age of 1.5 years. The outcome measures were repeated wheezing, use of inhaled corticosteroids, atopic dermatitis during the first 1.5 years of life and total serum immunoglobulin E (IgE). There were no significant associations between the genotypes or allele frequencies of TLR7 rs179008, TLR8 rs2407992, TLR9 rs187084 or TLR10 rs4129009 polymorphisms and clinical characteristics or the severity of bronchiolitis during hospitalization. During follow-up, repeated wheezing was more common in children with TLR9 rs187084 variant genotype CC (30.5%) than in children with TLR9 wild-type genotype TT (12.2%) (p = 0.02, aOR 2.73, 95% CI 1.02–7.29). The TLR10 rs4129009 minor allele G was associated with elevated total serum IgE. TLR9 rs187084 gene polymorphism may be associated with post-bronchiolitis wheezing, and TLR10 rs4129009 gene polymorphism may be associated with atopy.

Bronchiolitis is the most common lower respiratory tract infection (LRTI) in young children1. Among the various respiratory viruses causing bronchiolitis, respiratory syncytial virus (RSV) is the single most important one2. The clinical course of primary RSV infection is highly variable, and genetic variations in genes regulating the immune response evidently are important in determine whether a child suffers from a mild upper respiratory infection or a more severe LRTI-like bronchiolitis after exposure to RSV3.

Bronchiolitis in infancy is associated with subsequent wheezing in early childhood 4. The mechanisms of virus-induced wheezing and the role of airway hyper-responsiveness, however, are poorly understood. Signalling via toll-like receptors (TLRs) seems to play an important role in triggering airway inflammation5,6.

TLRs are key molecules in innate immunity that detect conserved structures, which are present in a broad range of pathogens, and either promote or inhibit inflammatory and immune responses7. TLR3, TLR7, TLR8 and TLR9 recognize viral products responding to viral double-stranded (ds) RNA, viral single-stranded (ss) RNA or cytoxic granule proteins containing DNA from certain bacteria and some viruses, respectively8,9. TLR10 is, in addition to TLR1, TLR2 and TLR6, a member of the TLR2 subfamily. Although TLR10 is a pattern-recognition protein without known ligand specificity, there is evidence that it is a modulatory receptor with mainly inhibitory properties10.

It has been reported that genetic factors might influence susceptibility to RSV infection in early life. TLR4 gene polymorphisms have been associated with severe RSV infection11,12. In addition, TLR9 and TLR10 gene polymorphisms13 and TLR 3 gene polymorphisms14 were associated with RSV bronchiolitis.

As the innate immune system is an important link between environmental exposure and the regulation of cytokine responses, alterations in innate immunity may be fundamental to the balance between Th1- and Th2-oriented responses and to the subsequent development of asthma and allergy. In a recent review on the

relationship between genes encoding TLRs and asthma risk, an association was found between TLR9 gene polymorphisms and asthma. There is more evidence that polymorphisms in the TLR7 and TLR8 genes are related to asthma and allergy, as well as to susceptibility to respiratory viral infections. We have prospectively followed a group of children hospitalized for bronchiolitis at age less than 6 months. We have earlier studied the TLR1 rs5743618, TLR2 rs5743708, TLR3 rs3775291, TLR4 rs4986790 and TLR6 rs5743810 polymorphisms, and reported their associations with bronchiolitis and post-bronchiolitis outcomes. The aim of the present study was to complement this exploratory study series by evaluating whether the TLR7 rs179008, TLR8 rs2407992, TLR9 rs187084 and TLR10 rs4219009 polymorphisms are associated with the presence, clinical characteristics and viral etiology of bronchiolitis in early infancy. In addition, we studied whether there are associations between these polymorphisms and post-bronchiolitis outcomes including subsequent infections, post-bronchiolitis wheezing, need for corticosteroid treatment and atopic manifestations until the age of 1.5 years.

Results

Cases versus controls. The genotypes and allele frequencies of cases (children hospitalized with bronchiolitis) and controls (healthy children from a birth cohort study) did not differ substantially with respect to TLR7 rs179008, TLR8 rs2407992, TLR9 rs187084 or TLR10 rs4219009 polymorphisms (Table 1). Because TLR7 rs179008 and TLR8 rs2407992 are located on the X chromosome, the data are given separately for boys and girls. The studied alleles of TLR9 and TLR10 were in HWE. Because TLR7 and TLR8 genes are located on the X chromosome, HWE was not studied.

Hospitalization in infancy. The mean age of the 135 bronchiolitis patients was 10.0 weeks (range 1–25 weeks, SD 6.94) during hospitalization. The study included 65 (48.1%) boys (Table 2). The causative virus was RSV in 101 (74.8%) cases and rhinovirus in 11 (8.1%) cases. Influenza A virus was found in 7 (5.2%) and human metapneumovirus in 2 (1.5%) cases, and parainfluenzavirus type 3 (PIV3) was found in 1 (0.8%) case. Two different viruses were detected in 8 (5.9%) samples; rhinovirus and adenovirus in two, and rhinovirus and bocavirus in two samples, and RSV and adenovirus, RSV and bocavirus, Influenza A and bocavirus, and PIV3 and adenovirus, each in one sample. There were no differences in the clinical picture or in the outcomes between cases with multiple viruses vs. a single virus detected. The sample was negative for studied viruses in 13 (9.6%) cases.

Table 1. The genotypes and allele frequencies of TLR7 rs179008 (171 A/T), TLR8 rs2407992 (2040 C/G), TLR9 rs187084 (1486 T/C) and TLR10 rs4219009 (2322 A/G) in the bronchiolitis patients (cases) and population-based controls. The test showed heterozygosis of the TLR7 gene in four controls and heterozygosis of the TLR8 gene in four controls, although the subjects were male. In one male control, the test results showed heterozygosis of both TLR7 and TLR8. These seven controls were deleted from the analyses. There were no statistically significant differences between cases and controls.
The length of hospital stay (LOS) was mean 5.2 days (SD 3.4, range 1–25) in all 70 cases. Major allele vs minor allele. The length of hospital stay (LOS) was mean 5.2 days (SD 3.4, range 1–25) in all 70 cases. Major allele vs minor allele.

Parents reported that 30 children (23.3%) had doctor-diagnosed food allergy and 18 children (14.0%) had recurrent otitis media in 22 (68.8%) of the 32 minor allele C carriers vs. in 13 of the 33 (39.4%) major allele G carriers (p = 0.04) (Table 6). However, the significance of this association was lost when adjusted for age (OR 2.75, 95% CI 0.96–7.85). In females, the result was of the same direction but not statistically significant (p = 0.06) (Table 7). There was a non-significant finding that the TLR7 major allele A, when present as homozygous, was connected to recurrent otitis media in females (p = 0.07) (Table 7), but this was not seen in males (Table 6).

### Table 2. Clinical characteristics of the bronchiolitis population during hospitalization and follow-up visit at the mean age of 1.5 years.

| Infants during bronchiolitis N = 135 | Boys N(%) | RSV N (%) | Feeding support N (%) | Oxygen supplementation N(%) | Length of hospital stay (mean, range, SD) |
|------------------------------------|-----------|------------|-----------------------|----------------------------|------------------------------------------|
| Age (mean, range, SD)              | 10.0 weeks (1–25, SD 6.94) | 65 (48.1) | 101 (74.8) | 45 (33.3) | 25 (18.5) | 4.74 days (0–22, SD 4.74) |

### Table 3. Genotypes and major allele frequencies of TLR7 rs179008 and TLR8 rs4207992 genes in 70 female patients in relation to clinical characteristics of bronchiolitis. The length of hospital stay (LOS) was mean 5.2 days (SD 3.4, range 1–25) in all 70 cases. Major allele vs minor allele.

There were no significant associations between the TLR7 rs179008 or TLR8 rs4207992 genotypes or allele frequencies and the clinical characteristics of bronchiolitis in females (Table 3). Instead, the presence of the minor allele T in the TLR7 rs179008 gene in males was associated with the RSV aetiology of bronchiolitis (100% vs. 70.4% in those with the major allele A) and with the need for feeding support (54.5% vs. 33.3%) (Table 4). The viral aetiology of bronchiolitis, and the need for feeding support or oxygen supplementation during bronchiolitis hospitalization did not differ between the children with different genotypes or allele frequencies of TLR9 rs187084 or TLR10 rs4219009 (Table 5). The LOS in hospital was roughly equal in all the groups constructed on the basis of TLR7 rs179008, TLR8 rs4207992, TLR9 rs187084 or TLR10 rs4219009 polymorphisms.

### Follow-up for 1.5 years.

In all, 129 toddlers attended the follow-up visit at the mean age of 18.1 months (range 13–25 months, SD 2.35). There were 24 (19.4%) children who had presented with repeated wheezing (≥2 episodes) during the follow-up period and 16 (12.4%) children who had used inhaled corticosteroids (ICSs). Parents reported that 30 children (23.3%) had doctor-diagnosed food allergy and 18 children (14.0%) had recurrent otitis media in 22 (68.8%) of the 32 minor allele C carriers vs. in 13 of the 33 (39.4%) major allele G carriers (p = 0.04) (Table 6). However, the significance of this association was lost when adjusted for age (OR 2.75, 95% CI 0.96–7.85). In females, the result was of the same direction but not statistically significant (p = 0.06) (Table 7). There was a non-significant finding that the TLR7 major allele A, when present as homozygous, was connected to recurrent otitis media in females (p = 0.07) (Table 7), but this was not seen in males (Table 6).
Table 5. Genotypes and major allele frequencies of TLR7 rs179008 and TLR8 rs2407992 genes in 65 male patients in relation to the clinical characteristics of bronchiolitis. The length of hospital stay (LOS) was mean 4.3 days (SD 3.0, range 0–15) in all 65 cases.

Table 4. Genotypes and major allele frequencies of TLR7 rs179008 and TLR8 rs2407992 genes in 65 male patients in relation to the clinical characteristics of bronchiolitis. The length of hospital stay (LOS) was mean 4.7 days (SD 3.2, range 0–22) in all 133 cases. NC not calculated. Major allele vs minor allele.

Former bronchiolitis patients with the homozygous variant TLR9 rs187084 genotype CC had repeated wheezing more often (30.5%, p = 0.02) than children with the wild-type genotype TT (12.2%) during the follow-up period until the age of 1.5 years (Table 8). The OR was 2.66 (95% CI 1.01–7.06) when adjusted for age and sex, and 2.73 (95% CI 1.02–7.29) when adjusted further for atopic dermatitis. There were no significant associations between TLR7 rs179008, TLR8 rs2407992 or TLR10 rs4219009 gene polymorphisms and repeated wheezing.

Children with TLR10 rs4219009 genotype AG (no child had the GG genotype) had more often had elevated total serum IgE than children with TLR10 genotype AA (Table 7). The OR was 3.79 (95% CI 1.25–11.56) when adjusted further for atopic dermatitis. There were no significant associations between TLR7 rs179008, TLR8 rs2407992 or TLR9 rs187084 gene polymorphisms and total serum IgE, food allergy or atopic dermatitis during the first 1.5 years of life.

Discussion
Our study was an exploratory study on the possible association between the TLR7 rs179008, TLR8 rs2407992, TLR9 rs187084 or TLR10 rs4219009 gene polymorphisms and characteristics of bronchiolitis in early infancy or post-bronchiolitis outcomes. The main result was that the TLR9 rs187084 polymorphism was associated with repeated wheezing until the age of 1.5 years after bronchiolitis at age less than 6 months. One-third of children who were homozygous for the variant genotype CC had suffered from repeated wheezing, compared to 12.2% of other former bronchiolitis patients. Another important result was that the TLR10 rs4219009 minor allele G was associated with elevated total serum IgE in infancy. However, such associations were not seen in the case of clinical findings, i.e., food allergy or atopic dermatitis during the first 1.5 years of life. Both these results remained significant when adjusted for the most important confounders. In addition, we revealed a preliminary association between the presence of the TLR8 rs4207992 minor allele C and recurrent otitis media in males but not in females.

However, polymorphisms TLR7 rs179008, TLR8 rs2407992, TLR9 rs187084 and TLR10 rs4219009 were not associated with the characteristics of bronchiolitis, including those reflecting bronchiolitis severity. All patients
with bronchiolitis required hospitalization; one-fourth received supplementary oxygen; one-third required feeding support during hospitalization. Viruses such as RSV are recognized after invasion of the cells by those viral-sensing TLRs and other pattern-recognition proteins, which are located within endosomes.

In previous studies, TLR4 gene polymorphisms have been associated with RSV infections, and there is preliminary evidence that TLR3 gene polymorphism, and TLR9 and TLR10 gene polymorphisms as well, may be associated with RSV bronchiolitis. In this exploratory study, bronchiolitis cases and population-based controls did not differ significantly for genotypes or allele frequencies of TLR7 rs187084, TLR9, and TLR10.

In a recent systematic review and meta-analysis, TLR9 rs5743836 gene polymorphism was associated with increased asthma risk. TLR9 recognizes bacterial and viral CpG-DNA. In an experimental study, the TLR9 gene polymorphism was associated with asthma and allergic rhinitis. Our finding is in disagreement with the results of a previous study, in which the TLR8 rs4207992 gene polymorphism, also used in the present study, was associated with RSV infections. Nonetheless, TLR9 rs187084 polymorphism as applied in this study has also been shown to be functional, being associated with immunity against certain infectious diseases such as tuberculosis and malaria. Moreover, that polymorphism was associated with airway hyper-responsiveness in four population-based samples from Canada and Australia. In our present study, the TLR9 rs187084 polymorphism was associated with repeated post-bronchiolitis wheezing. In this same cohort, TLR3 rs3775291 gene polymorphism was associated with repeated wheezing after bronchiolitis in infancy.

The association of the TLR10 gene with asthma has been documented in European-American populations. Two-thirds of children who have repeated post-bronchiolitis wheezing until the age of two years are “transient wheezers” which means that they will grow out of their wheezing tendency by or at school age. The risk of allergic asthma that is associated with the TLR10 gene polymorphism was minor in our patients with bronchiolitis in early infancy. However, we found an association between TLR10 rs4219009 gene polymorphism and elevated total serum IgE, and based on many studies, atopy and atopic sensitization are well-known risk factors of allergic asthma, in post-bronchiolitis cohorts as well.

TLR7 rs179008 and TLR8 rs2407992 gene polymorphisms, located on the X chromosome, were not associated with post-bronchiolitis outcome measures in either boys or girls. In earlier studies, TLR7 and TLR8 polymorphisms were associated with asthma and allergic rhinitis. Our finding is in disagreement with the results of a previous study, in which the TLR8 rs4207992 gene polymorphism, also used in the present study, was associated with asthma, atopic dermatitis, allergic rhinitis and elevated serum allergen-specific IgE. In experimental studies, concomitant TLR7 gene deficiency and early Pneumovirus infection predisposed mice toward the development of asthma-like pathology. In the present cohort, 19.4% of children suffered from repeated post-bronchiolitis virus-induced wheezing until 1.5 years of age. However, allergic asthma may develop later in childhood, even after many symptom-free years.

There were certain limitations in the present study. The number of patients was relatively small for a genetic study. The small number of patients meant a risk of type-2 statistical errors. On the other hand, we carried out multiple analyses for polymorphisms of four different TLR encoding genes, which risked type-1 statistical errors. Because the data on TLR7, TLR8, TLR9 and TLR10 genes as risk factors for bronchiolitis, early-childhood wheezing and childhood asthma are mainly lacking, our study was an exploratory one with no purpose to test.

**Table 6.** Genotypes and major allele frequencies of TLR7 rs179008 and TLR8 rs2407992 genes in 62 male bronchiolitis patients in relation to outcome variables during the post-bronchiolitis follow-up until the age of 1.5 years.

| TLR7 males Outcome variables, N = 62 | A present N = 54, No. (%) | T present N = 11, No. (%) |

and diffuse wheezes and/or crackles. The viral aetiology of bronchiolitis was studied by antigen detection and transcription of antibiotics, and the use of corticosteroids for wheezing after hospitalization for bronchiolitis. The interviewed using a structured questionnaire on the occurrence of otitis media, and wheezing episodes, the pre-

94%, and feeding support was defined as a need for intravenous fluids or feeding via a nasogastric tube. The strengths of the present study were the prospective design, an extensive virological test panel available during hospitalization for bronchiolitis and careful data collection during bronchiolitis and at the subsequent control visit including e.g. daily diaries recordings by parents. The homogeneity of study populations, as in the present study, is a clear benefit in genetic studies.

In conclusion, we found preliminary evidence that TLR9 polymorphisms may be associated with post-bronchiolitis wheezing. This finding needs to be confirmed or ruled out in subsequent confirmatory studies.

**Methods**

**Bronchiolitis patients.** Previously healthy, full-term infants hospitalized for bronchiolitis at less than 6 months of age during the period December 1, 2001 through May 31, 2002 and during the period from October 28, 2002 through May 31, 2004 were enrolled in the study. In all, 187 eligible infants were hospitalized for the first time during the two study periods. Appropriate clinical data including viral findings and gene polymorphisms were available from 135 infants. Bronchiolitis was defined as an acute LRTI characterized by rhinorrhea, cough, and diffuse wheezes and/or crackles. The viral aetiology of bronchiolitis was studied by antigen detection and polymerase chain reaction (PCR) in nasopharyngeal aspirates (NPA), as described recently. The studied viruses were RSV, human rhinovirus (hRV), human metapneumovirus (hMPV), InfluenzaA virus, Parainfluenza3 virus (PIV3), adenovirus and human bocavirus (hBoV). Data on disease severity, such as the need for supplementary oxygen was given when oxygen saturation (SaO₂) measured with pulse-oximetry was less than 94%, and feeding support was defined as a need for intravenous fluids or feeding via a nasogastric tube.

After hospitalization for bronchiolitis, the children were invited to a follow-up visit at 1.5 years of age (on average), and 129 (92.8% of those invited; 69.0% of those hospitalized) attended. At the follow-up visit, the parents were interviewed using a structured questionnaire on the occurrence of otitis media, and wheezing episodes, the prescription of antibiotics, and the use of corticosteroids for wheezing after hospitalization for bronchiolitis. The parents had recorded a diary during the 1.5 years post-bronchiolitis follow-up period, including descriptions of all infections and wheezing periods verified by a family doctor or a paediatrician. The study physician and the parents checked together the diaries at the control visit. The doctor-diagnosed episodes were recorded for the analyses.

Food allergy and atopic dermatitis, although reported by parents, were registered during hospitalization and at the control visit on average 1.5 years later—only doctor-diagnosed cases were included. A blood sample for immunoglobulin E (IgE) measurement was taken at the follow-up visit at the age of 1.5 years. Total serum IgE was determined by electro-chemiluminescence (ECLIA, Roche Diagnostics GmbH, Mannheim, Germany) according to laboratory practice. Serum IgE was considered to be elevated if the concentration was more than +2SD above the mean of non-atopic Finnish children (>60 IU/ml). Corticosteroid treatment meant maintenance medication periods with inhaled corticosteroids (ICSs) for repeated wheezing or suspected asthma. Repeated wheezing was defined as two or more wheezing episodes during the post-bronchiolitis follow-up period.

Frozen whole-blood samples were available for TLR7 rs179008, TLR8 rs2407992, and TLR10 rs4129009 genotyping from all 129 children. Samples for TLR9 rs187084 genotyping were available from 127 children.

### Table 7. Genotypes and major allele frequencies of TLR7 rs179008 and TLR8 rs2407992 genes in 67 female bronchiolitis patients in relation to outcome variables during the post-bronchiolitis follow-up until the age of 1.5 years. Major allele vs minor allele.

Table 8. Genotypes and major allele frequencies of TLR9 rs187084 (N = 127) and TLR10 rs4219009 (N = 129) genes in bronchiolitis patients in relation to outcome variables during the post-bronchiolitis follow-up until the age of 1.5 years. Major allele vs. minor allele.

Genetic studies. The genotyping of TLR8 rs2407992 (2040 C/G) was performed by pyrosequencing as described for TLR3 rs3775291 (1234 C/T)[14]. For TLR7 rs179008 (171 A/T), the PCR products were first purified using the QIA quick PCR Purification Kit (Qiagen, Hilden, Germany) according to the manufacturer’s protocol. PCR products with low deoxyribonucleic acid (DNA) content were eluted to 30 μl of elution buffer. After purification, the PCR products were pipetted to a 96-well plate (5μl) together with TLR7 rs179008 (171 A/T) forward primer (1.6μl). The 96-well plate was sent to the Institute for Molecular Medicine laboratory in Helsinki, Finland for sequencing. TLR9 rs187084 (1486 T/C) genotyping was performed using BspTI restriction enzyme (Thermo Fisher Scientific, Waltham, USA) for the digestion of PCR product[36]. High-resolution melting analysis (HMR) (Roche Diagnostics Light Cycler 480, Basel, Switzerland), was used to genotype TLR10 rs4129009 (2322 A/G) as described earlier[36]. The methods were described recently in more details[36]. The PCR and sequencing primers used for the TLR7, TLR8, TLR9, and TLR10 genes are described in Table 9. All the primers were purchased from Sigma-Aldrich, Finland.

Controls. TLR7 rs179008 and TLR8 rs2407992 polymorphisms were examined in two-month-old healthy Finnish infants, who participated in the Steps to Children’s Healthy Development and Wellbeing study (STEPS), which is a prospective birth cohort study of approximately 1,800 children[17]. No selection criteria were applied in the recruitment of children for the STEPS Study or for inclusion in the subgroup with TLR genotyping. DNA was extracted from blood collected at the age of two to three months in 412 subjects, who visited the study clinic in the recruitment of children for the STEPS Study or for inclusion in the subgroup with TLR genotyping. DNA was extracted from blood collected at the age of two to three months in 412 subjects, who visited the study clinic in Turku, Finland[17]. Only 328 children were included as controls in the present study for TLR7rs179008, TLR8 rs2407992 and TLR10 rs 4129009 polymorphisms, due to the limited amount of DNA available from the infants who were not included. For TLR9 rs187084, there was enough DNA to analyze only 270 samples. The genotyping processes were identical in the bronchiolitis cohort and in the controls, except for the TLR10 rs4129009 gene. Determination of that polymorphism was performed by digestion similarly to TLR9 rs187084 in the control group, and by HRMA in the bronchiolitis cohort.

Ethics. The study was carried out in accordance with the approved guidelines of the WMA Declaration of Helsinki. Before we enrolled the children we obtained informed parental consent, including the use of samples for genetic studies on bronchiolitis and asthma risk, both during hospitalization and at the control visit. The protocol of the study was approved by the Ethics Committee of the Tampere University Hospital District, Tampere, Finland. The personal data of the study subjects were not given to the two laboratories that performed the genetic studies, the National Institute of Health and Welfare, Turku, Finland, and the Institute for Molecular Medicine, Helsinki, Finland. The genotyping of control children was done within the STEPS study, which was carried out in accordance with the approved guidelines of the WMA Declaration of Helsinki. The protocol was approved by the Ethics Committee of the Hospital District of Southwest Finland, Turku, Finland. The parents of participating children provided their written, informed consent.

Statistical analyses. Data were analyzed using SPSS package version 23.0 (IBM Corp. NY, USA). Chi square and Fisher’s exact tests were used for categorized variables. Student’s t-test was used for normally distributed variables. The Mann–Whitney test was used for non-normally distributed continuous variables. The results were expressed as frequencies, proportional frequencies, means, medians and standard deviations (SD).
Logistic regression was used for the multivariate analyses, adjusted for age, sex and atopic dermatitis during the first 1.5 years of life when appropriate. The results were expressed as odds ratios (OR) and 95% confidence intervals (95% CI). The FINETTI program was used to evaluate the Hardy–Weinberg equilibrium (HWE) of the studied TLR9 and TLR10 alleles studied.

Table 9. Primer sequences, allele and amino acid changes in toll-like receptor (TLR) genes TLR7 rs179008 (171A/T), TLR8 rs2407992 (2040C/G), TLR9 rs187084 (1486T/C) and TLR10 rs4129009 (2322A/G). TLR7 SNP was detected by common sequencing, TLR8 SNP by pyrosequencing, TLR9 by digestion and TLR10 by restriction enzyme VspI.

| TLR7 | TLR8 | TLR9 | TLR10 |
|------|------|------|-------|
| 171A/T | 2040C/G | 1486T/C | 2322A/G |

Author Contributions
K.N. had responsibility for protocol development, patient screening, data analysis and writing the manuscript. S.T. and P.K. had participated writing in the manuscript. J.V., J.T. and Q.H. had responsibility for the genetic analysis and participated in writing the manuscript. M.H. participated in the protocol development and writing the manuscript. V.P. had responsibility for the STEPS study, enrolling the control patients and arranging the laboratory analyses. He also participated in writing the manuscript. M.K. was responsible for the planning and interpretation of the analyses and participated in writing the manuscript.
