Mixed multiplier ideals and the irregularity of abelian coverings of the projective plane

Daniel Naie

Mathematical subject classification: 14E20, 14H20, 14Jxx

Abstract

A formula for the irregularity of abelian coverings of the projective plane is established and some applications are presented.

1 Introduction

The initial intent of this study was to extend the formula for the cyclic multiple planes from [17] to the case where the branching curve $C$ is not transverse to the line at infinity $H_{\infty}$. In the transverse case, if $S$ denotes a desingularization of the $\mathbb{Z}/n\mathbb{Z}$-cyclic covering of the plane associated to $C$ and $H_{\infty}$, then

$$q(S) = \sum_{\xi \text{ jumping number of } C} h^1(\mathbb{P}^2, O_{\mathbb{P}^2}(-3 + \xi \deg C) \otimes \mathcal{J}(\xi \cdot C)).$$

(1)

Hence, the irregularity is quasi-constant as a function of $n$, unlike what happens in the non transverse case, when, as we see in Example 4.4, the irregularity might be a degree 1 quasi-polynomial of $n$. To understand the difference and to extend the above formula to the non transverse case, we consider abelian instead of cyclic coverings. The role played by the multiplier ideals will be taken by the mixed multiplier ideals. Consequently, the goal of this paper is to apply the theory of mixed multiplier ideals to compute the irregularity of the abelian coverings of the projective plane.

If $X$ is a smooth surface and $a_1, \ldots, a_t \subset O_X$ are non-zero ideal sheaves, the mixed multiplier ideal $\mathcal{J}(a_1^{x_1} \cdots a_t^{x_t})$ varies with the rational vector $x = (x_1, \ldots, x_t) \in \mathbb{R}^t_+$. Proposition 2.2 and Proposition 2.7 assert that there is a set of hyperplanes called jumping walls with the following properties:

1. If the mixed multiplier ideal jumps, then the vector $x$ crosses a jumping wall. Consequently, the fibres of the map $x \mapsto \mathcal{J}(a_1^{x_1} \cdots a_t^{x_t})$ are finite unions of rational convex polytopes cut out by the jumping walls.

2. The jumping walls are determined by the jumping numbers of the simple complete relevant ideals (see Definition 2.6) associated to the ideals $a_i$.

These results together with O. Zariski’s original idea introduced in [23] enable us to generalize formula (1) to abelian coverings of the projective plane. Such a covering induces a partition of the branching curve, and the irregularity is expressed in Theorem 3.9 as a
linear combination of superabundances of linear systems defined in terms of some mixed
multiplier ideals associated to this partition. There exists a natural map from the Galois
group characters of the covering to the first orphant appearing in the definition of the mixed
multiplier ideals. The coefficient of each superabundance represents the number of charac-
ters that lie in the intersection of the jumping walls associated to the corresponding mixed
multiplier ideals. We refer the reader to Theorem 3.9 for the precise formula and note
here that it could be easily extended along the lines of Vaucié’s paper [22], to coverings of
smooth surfaces.

The proof of Theorem 3.9 occupies §3. In §4, the last part of the paper, some applications
are presented including E. Hironaka’s result from [6] concerning the asymptotic behaviour
of the irregularity of the abelian coverings, the discussion of the general cyclic coverings,
and the computation of the irregularity of the Hirzebruch surfaces constructed in [6]—
abelian coverings of the plane branched along configurations of lines, i.e. line arrangements.
F. Hirzebruch mainly deals with three arrangements and obtains three families of surfaces
with the covering group, for each family, a certain power of $\mathbb{Z}/n\mathbb{Z}$. For the three most
interesting examples, one in each family, namely those with $c_2^2 = 3c_2$, the computation
of the irregularity was performed by N.-M. Ishida in [6]. In [14], A. Libgober computed the
irregularity for two of the three families for general n. We find again one of Libgober’s
results, slightly correct the second, see Proposition 4.8, and perform the computation for
the third family.

In [1], N. Budur has obtained a general formula for the Hodge numbers $h^{0,q}$, $0 \leq q \leq n$,
of the abelian coverings of a smooth variety of dimension n. His proof is based on the theory
of local systems of rank 1, and the formula is expressed in terms of the number of certain
rational points inside convex polytopes (see [1, Theorem 1.3, Theorem 1.7]). A. Libgober
previously established in [14, §3.1] a formula for the irregularity of abelian coverings of the
plane, his technique being based on mixed Hodge structures. The computations, mentioned
above for the families of Hirzebruch surfaces, used this formula. His formula and ours bear
clear resemblances; it is a sum of superabundances of linear systems expressed in terms
of quasiadjunction ideals (see [15] for the relation between the quasiadjunction ideals and the
multiplier ideals) with coefficients given by quasiadjunction polytopes.

2 Mixed multiplier ideals and jumping walls

In this section we define and characterize the jumping walls associated to mixed multi-
plier ideals. We start by briefly recalling the notions of multiplier ideals and mixed multiplier
ideals for ideal sheaves on a smooth surface following [11].

Let $\mathfrak{a} \subset \mathcal{O}_X$ be a non-zero ideal sheaf on $X$ and let $\mu : Y \to X$ be a log resolution
of $\mathfrak{a}$ with $\mathfrak{a} \cdot \mathcal{O}_Y = \mathcal{O}_Y(-F)$. If $\xi$ is a positive rational number, then the multiplier ideal
associated to $\xi$ and $\mathfrak{a}$ is defined as

$$\mathcal{J}(\mathfrak{a}^\xi) = \mu_* \mathcal{O}_Y(K_\mu - [\xi F]).$$

Now, for the analogous notion for several ideals, let $\mathfrak{a}_1, \ldots, \mathfrak{a}_t \subset \mathcal{O}_X$ be non-zero ideals
and $\mu : Y \to X$ a common log resolution of the ideals $\mathfrak{a}_i$ with $\mathfrak{a}_i \cdot \mathcal{O}_X = \mathcal{O}_Y(-F_i)$ and
\[
\sum_i F_i + \text{except}(\mu) \text{ having simple normal crossing support}. \text{ If } \xi_1, \ldots, \xi_t \text{ are positive rational numbers, then the } \textit{mixed multiplier ideal} \text{ associated to the } \xi_i \text{ and the } a_i \text{ is}
\]
\[
J(a_1^{\xi_1} \cdots a_t^{\xi_t}) = \mu_* \mathcal{O}_Y(K_\mu - [\xi_1 F_1 + \cdots + \xi_t F_t]).
\]

**Definition-Lemma (see [10], Lemma 9.3.21).** Let \( a \subseteq \mathcal{O}_X \) be a non-zero ideal sheaf on \( X \) and let \( P \in X \) be a fixed point in the support of \( a \). Then there is an increasing sequence of positive rational numbers \( \xi_j = \xi_j(a, P) \) such that for every \( \xi \in [\xi_j, \xi_{j+1}) \),
\[
J(a^{\xi_j}) = J(a^{\xi}) \supset J(a^{\xi_{j+1}}).
\]

The rational numbers \( \xi_j \) are called the jumping numbers of the ideal sheaf \( a \) at \( P \).

The multiplier ideals and the jumping numbers are defined similarly in the context of effective \( \mathbb{Q} \)-divisors. By [10, Proposition 9.2.28], if \( C \) is a general element of the ideal sheaf \( a \) and \( \xi \) is a positive rational less than 1, then \( J(\xi \cdot C) = J(a^{\xi}) \). Moreover, for any integer divisor \( C \) through a point \( P \), the jumping numbers of \( C \) at \( P \) are periodic and determined by the ones lying in the unit interval \([0,1)\). Similarly, the jumping numbers of an ideal sheaf \( a \) at \( P \) are periodic and determined by the ones lying in the interval \([0,2)\). We refer the reader to [10, Example 9.3.24] for more ample details.

For the remainder of this section we consider \( a_1, \ldots, a_t \subseteq \mathcal{O}_X \) non-zero ideals such that the subscheme defined by each \( a_i \) is zero dimensional and supported at a fixed point \( P \in X \). We want to study the behaviour of the mixed multiplier ideal \( J(a_1^{\xi_1} \cdots a_t^{\xi_t}) \) as \( x = (x_1, \ldots, x_t) \) varies in the first orthant. If \( \mu : Y \to X \) is a log resolution defined as before, we shall denote by \( E_\rho \) the strict transforms of the exceptional divisors seen on \( Y \). There exists effective divisors \( B_\rho \) on \( Y \) such that \( (B_\rho) \) is the dual basis to \( (-E_\rho) \) of the lattice \( \Lambda_\mu = \bigoplus \mathbb{Z} E_\alpha \) with respect to the intersection form on \( Y \). The basis \( (B_\rho) \) is called the \textit{branch basis} of the resolution.

Next we want to define the notion of relevant divisors. We follow [20] but see also [4].

**Definition 2.1.** Let \( a \subseteq \mathfrak{m}_P \). A strict transform \( E_\rho \) in a log resolution of \( a \) is called a \textit{relevant divisor} of \( a \) at \( P \) if either
\[
E_\rho \cdot (E_\rho^0) \geq 3,
\]
where \( E_\rho^0 = (\mu^* C)_{\text{red}} - E_\rho \) with \( C \) the curve defined by a general element of \( a \), or \( E_\rho \) corresponds to an arrowhead vertices of the augmented Enriques tree of \( C \) at \( P \). The index \( \rho \) will be referred to as a \textit{relevant position}.

Note that the difference with respect to the notion introduced in [20] comes from the fact that we consider jumping numbers associated to ideal sheaves. For example, for the ideal of a knot, the exceptional divisor becomes a relevant divisor.

The set of relevant positions of \( a \) at \( P \) will be denoted by \( \mathcal{R} = \mathcal{R}_P(a) \). The following proposition stresses the importance of the relevant divisors, or positions, in the computation of mixed multiplier ideals. It will further lead us to the notion of jumping walls associated to the ideal sheaf \( a_1 \cdots a_t \) at \( P \).
PROPOSITION 2.2. Let $a_1, \ldots, a_t \subset \mathcal{O}_X$ be non-zero ideals such that the subscheme defined by each $a_i$ is zero dimensional and supported at a fixed point $P \in X$. Let $\mu : Y \to X$ be a log resolution of $a$ and $\mathcal{R}$ the set of relevant positions of $a$ at $P$. If $x_i$ are positive rational numbers, then

$$J(a_1^{x_1} \cdots a_t^{x_t}) = \mu_* \mathcal{O}_Y \left( K_\mu - \sum_{\rho \in \mathcal{R}} \left\lfloor x_i e_i^\rho \right\rfloor E_{\rho} \right),$$

where for every $i$, $a_i \cdot \mathcal{O}_Y = \mathcal{O}_Y(-\sum_\alpha e_i^\alpha a_\alpha)$.

Proof. Consider $y = cx$ with $c \in [0, 1]$. If $c = 1$ then $y = x$ and as $c$ decreases, the coefficients $\lfloor \sum_i x^i e_i^\alpha \rfloor$ decrease by discrete jumps behind. More precisely, there is a finite sequence of rationals $0 = c_{g+1} < c_g < c_{g-1} < \cdots < c_1 < c_0 = 1$ with the following properties holding for any $0 \leq l \leq g$:

1) for any $c \in [c_{l+1}, c_l)$, and for any $\alpha \notin \mathcal{R}$, $\lfloor c_{l+1} \sum_i x^i e_i^\alpha \rfloor = \lfloor c_l \sum_i x^i e_i^\alpha \rfloor$;

2) there exists $\mathcal{B}(l)$ disjoint from $\mathcal{R}$ such that for any $\beta \in \mathcal{B}(l)$,

$$\left\lfloor c_{l+1} \sum_i x_i^\beta e_i^\alpha \right\rfloor = \left\lfloor c_l \sum_i x_i^\beta e_i^\alpha \right\rfloor - 1 = c_l \sum_i x_i^\beta - 1;$$

3) for any $\alpha \notin \mathcal{B}(l) \cup \mathcal{R}$, $\lfloor c_{l+1} \sum_i x^i e_i^\alpha \rfloor = \lfloor c_l \sum_i x^i e_i^\alpha \rfloor$.

Set

$$\Delta_l = \sum_{\alpha \notin \mathcal{R}} \left\lfloor c_l \sum_i x_i^\beta e_i^\alpha \right\rfloor E_{\alpha} - \sum_{\rho \in \mathcal{R}} \left\lfloor \sum_i x_i^\beta e_i^\rho \right\rfloor E_{\rho}. $$

To end the proof, it is sufficient to show that $\mu_* \mathcal{O}_Y (K_\mu + \Delta_{l+1}) = \mu_* \mathcal{O}_Y (K_\mu + \Delta_l)$ for any $0 \leq l < g$. Set $\Gamma = \sum_{\beta \in \mathcal{B}(l)} E_{\beta}$. We have the following:

**Claim.** For any $\Gamma' \subset \Gamma$ and $E_\gamma \subset \Gamma'$ an irreducible component,

$$\mu_* \mathcal{O}_Y (K_\mu + \Delta_l + \Gamma' - E_\gamma) = \mu_* \mathcal{O}_Y (K_\mu + \Delta_l + \Gamma').$$

We justify the claim only when $x_i$ are less than 1. The general case is similar, but one needs to consider the general form of [11, Proposition 9.2.28]. Let $C_1, \ldots, C_l$ be the curves defined by general elements in $a$. Using 1) and 2) above we have

$$-\Delta_l \cdot E_\gamma \geq \sum_\alpha \left\lfloor c_l \sum_i x_i^\beta e_i^\alpha \right\rfloor E_{\alpha} \cdot E_\gamma > \sum_{\beta \in \mathcal{B}(l)} c_l \sum_i x_i^\beta E_{\beta} \cdot E_\gamma + \sum_{\alpha \notin \mathcal{B}(l)} \left( c_l \sum_i x_i^\beta - 1 \right) E_{\alpha} \cdot E_\gamma + \sum_i \left( c_l x_i^1 - 1 \right) \tilde{C}_1 \cdot E_\gamma = c_l \sum_i x_i^\mu \mu^* C_i \cdot E_\gamma - ((\mu^* C)_{red} - \Gamma) \cdot E_\gamma.

Hence

$$(\Delta_l + \Gamma' - E_\gamma) \cdot E_\gamma < ((\mu^* C)_{red} - \Gamma) \cdot E_\gamma + (\Gamma' - E_\gamma) \cdot E_\gamma \leq E_0^\gamma \cdot E_\gamma \leq 2$$

(3)
since \( \gamma \notin \mathcal{R}_P \). Now, tensoring the structure sequence of \( E_\gamma \) in \( Y \) with \( \mathcal{O}_Y(K_\mu + \Delta_l + \Gamma') \) and pushing it down to \( X \), we get the exact sequence

\[
0 \to \mu_*\mathcal{O}_Y(K_\mu + \Delta_l + \Gamma' - E_\gamma) \to \mu_*\mathcal{O}_Y(K_\mu + \Delta_l + \Gamma') \to H^0(E_\gamma, K_{E_\gamma} + (\Delta_l + \Gamma' - E_\gamma)|_{E_\gamma}).
\]

The last term vanishes by \( \text{(3)} \) justifying the claim.

From the properties \( 2) \) and \( 3) \), \( \Delta_{l+1} = \Delta_l + \Gamma \). By repeatedly using the claim, we obtain the result.

Next, we want to define the *jumping walls* associated to the mixed multiplier ideals \( \mathcal{J}(a_1^{\rho_1} \cdots a_l^{\rho_l}) \) when \( x = (x^1, \ldots, x^t) \) varies in the first orthant. The idea is that by the previous result, such a mixed multiplier ideal varies only when the point \( x \) crosses certain hyperplanes defined by equations corresponding to relevant positions. The defining equation of such a hyperplane is of the form

\[
\sum_{i=1}^{t} x^i e_i^\rho = r, \tag{4}
\]

with \( \rho \in \mathcal{R} \) and \( r \) a positive integer.

**Definitions 2.3.** A *relevant value* associated to the relevant position \( \rho \in \mathcal{R} \) of the ideal \( a_1 \cdots a_l \) is a positive integer \( r \) such that there may be found a point \( y \) in the hyperplane \( H : \sum_{i=1}^{t} x^i e_i^\rho = r \) and a neighbourhood \( V \) of \( y \) with the property that the mixed multiplier ideal \( \mathcal{J}(a_1^{\rho_1} \cdots a_l^{\rho_l}) \) corresponding to \( x \in V \), changes if and only if \( x \) crosses \( H \). The pair \( (\rho, r) \) is called a *relevant pair* and the hyperplane \( H \) a *jumping wall*.

When we speak of a relevant value, we mean a positive integer which is the relevant value associated to a certain relevant position. Of course, such a value might be associated to many relevant positions, but the position we refer to will be clearly identified in the context.

**Remark 2.4.** If \( a \) is a simple complete ideal, the relevant values associated to the relevant position \( \rho \) are the integers \( \xi e_\rho \), where \( e_\rho \) is the coefficient of the strict transform \( E_\rho \) in the minimal log resolution of \( a \) and \( \xi \) runs over all the jumping numbers contributed by \( \rho \). We refer the reader to [14] [15] for a formula producing all these jumping numbers.

**Example 2.5.** Let \( a_1 = (u^3, v^2) \) and \( a_2 = (u^6, v^2) \) be ideals in \( \mathbb{C}[u, v] \). Let \( E_1, E_2 \) and \( E_3 \) be the exceptional divisors necessary for the minimal log resolution of \( a_1 \) and let \( E_4 \) be the supplementary exceptional divisor necessary for finishing the minimal log resolution of \( a_2 \). Clearly, if \( C_i \) are general elements in each \( a_i \), then \( \mu^*(C_1 + C_2) = \tilde{C}_1 + \tilde{C}_2 + 4E_1 + 7E_2 + 12E_3 + 9E_4 \). The divisors \( E_3 \) and \( E_4 \) are the only relevant divisors. Then 5 and 7 are the first relevant values associated to the relevant divisor \( E_3 \) with the jumping walls \( H_{(3, r)} : 6x^1 + 6x^2 = r, r = 5, 7 \). Moreover, 4 and 5 are the first relevant values associated to \( E_4 \) with the jumping walls \( H_{(4, r)} : 3x^1 + 6x^2 = r, r = 4, 5 \).

The point \( y \) from the definition of the jumping wall \( H_{(4, 4)} \) can by any point on \( H_{(4, 4)} \cap \mathbb{R}_+^2 \) with \( y^1 < 1/3 \). The other points in the intersection do not satisfy the property in the definition of the relevant value. If \( y^1 > 1/3 \) then on a sufficiently small neighbourhood of \( y \), the mixed multiplier ideal \( \mathcal{J}(x^1 C_1 + x^2 C_2) \) equals the maximal ideal \( (u, v) \). If \( y = (1/3, 2/3) \)
then the multiplier ideal also changes when it crosses the wall $H_{(3,5)} : 6x^1 + 6x^2 = 5$. In the figure above, if $\mathfrak{a}$ lies in the open shaded polygon, then the mixed multiplier ideal equals the maximal ideal.

For practical reasons, what we have to do next is to determine a relatively small set of candidates for the relevant values associated to $\rho$.

**Definition 2.6.** Let $\rho$ be a relevant position for the ideal $\mathfrak{a}$ and $\mu$ a log resolution. The relevant ideal associated to $\mathfrak{a}$ and $\rho$ is the simple complete ideal $\mu_* \mathcal{O}_Y(-B_\rho)$, where $B_\rho$ is the rho element in the branch basis of the resolution.

**Proposition 2.7.** Let $a_1, \ldots, a_t \subset \mathcal{O}_X$ be non-zero ideals such that the subscheme defined by each $a_i$ is zero dimensional and supported at a fixed point $P \in X$. Let $\mu : Y \to X$ be a log resolution of $a = a_1 \cdots a_t$ with $(B_\alpha)$ the branch basis of the resolution. Then the set of relevant values associated to the relevant position $\rho$ is contained in the set of relevant values associated to $\rho$ of the relevant ideal $\mu_* \mathcal{O}_Y(-B_\rho)$.

**Proof.** It is sufficient to consider the case $t \geq 2$. Let $\rho_0$ be a relevant position and $r$ a relevant value with $H : \sum_{i=1}^t x^i e^{\rho_0}_i = r$ the corresponding hyperplane. The point $y$ may be chosen such that $H$ is the only jumping hyperplane containing it. It is here that we need $t \geq 2$. Using Proposition 2.2, since

$$\mu_* \mathcal{O}_Y(K_\mu - \sum_i y^i F_i) \subset \mu_* \mathcal{O}_Y(K_\mu - \sum_i y^i F_i + E_{\rho_0}) = \mu_* \mathcal{O}_Y(K_\mu - \sum_i (1 - \varepsilon) y^i F_i)$$

with $0 < \varepsilon \ll 1$, we get that

$$\mu_* \mathcal{O}_Y(K_\mu - \sum_{\rho \in \mathcal{N}} r^\rho E_\rho) \subset \mu_* \mathcal{O}_Y(K_\mu - \sum_{\rho \neq \rho_0} r^\rho E_\rho - (r - 1)E_{\rho_0}).$$

Setting $K_\mu = \sum a k^\alpha E_\alpha$ and $b = \mu_* \mathcal{O}_Y(-\sum_{\rho \neq \rho_0} (r^\rho - k^\rho) E_\rho)$, it follows that

$$b \cap \mu_* \mathcal{O}_Y((k^\rho_0 - r)E_{\rho_0}) \subset b \cap \mu_* \mathcal{O}_Y((k^\rho_0 - r + 1)E_{\rho_0}),$$

i.e. that $\mu_* \mathcal{O}_Y((k^\rho_0 - r)E_{\rho_0}) \subset \mu_* \mathcal{O}_Y((k^\rho_0 - r + 1)E_{\rho_0})$. Now, set $q = \mu_* \mathcal{O}_Y(-B_{\rho_0})$. The Enriques tree associated to $\mu' : Y' \to X$, the minimal log resolution of $q$, is the path from the root to the vertex $P_{\rho_0}$ of the Enriques tree associated to $a$. Let $\mathfrak{V}'$ be the set of vertices
of this path and $\mathcal{R}' \subset \mathcal{R} \cap \mathcal{Y}'$ the set of relevant positions. If $q \cdot \mathcal{O}_{\mathcal{Y}'} = \mathcal{O}_{\mathcal{Y}'} \left(- \sum_{\alpha \in \mathcal{V}'} e^\alpha E_\alpha \right)$, let $\mathcal{R}'' \subset \mathcal{R}'$ be the subset of relevant positions such that for any $\rho \in \mathcal{R}''$, $re^\rho/e^{\rho_0}$ is an integer. Then, using again Proposition 2.2 and the previous strict inclusion,

$$
J(\mathcal{O}_{\mathcal{Y}'}(q r/e^{\rho_0}) = \mu_* \mathcal{O}_{\mathcal{Y}'} \left( K_{\mu'} - \sum_{\rho \in \mathcal{R}'} \frac{r e^\rho}{e^{\rho_0}} E_\rho \right) = \mu_* \mathcal{O}_{\mathcal{Y}'} \left( \sum_{\rho \in \mathcal{R}''} \left( k^\rho - \frac{r e^\rho}{e^{\rho_0}} \right) E_\rho \right)
$$

\[ \subset \mu_* \mathcal{O}_{\mathcal{Y}'} \left( \sum_{\rho \in \mathcal{R}'' \setminus \mathcal{R}'} \left( k^\rho - \frac{r e^\rho}{e^{\rho_0}} \right) E_\rho + \sum_{\rho \in \mathcal{R}'} \left( k^\rho - \frac{r e^\rho}{e^{\rho_0}} + 1 \right) E_\rho \right) = J(q (1-\varepsilon) r/e^{\rho_0}), \]

where $0 < \varepsilon \ll 1$. Hence $r/e^{\rho_0}$ is a jumping number of $\mu_* \mathcal{O}_{\mathcal{Y}'}(-B_{\rho_0})$ associated to the relevant position $\rho_0$. □

**Example 2.8.** Let $a_1$ and $a_2$ be simple complete ideals supported at $P$. We want to show that for a relevant position $\rho$, the set of relevant values of the ideal $\mu_* \mathcal{O}_{\mathcal{Y}'}(-B_{\rho})$ are indeed needed, i.e. that the union of the sets of relevant values of each ideal $a_i$ associated to $\rho$ is not sufficient. Let $C_1$ and $C_2$ be two unibranch curves, general elements in $a_1$ and $a_2$, and let the associated augmented Enriques tree of the minimal log resolution of $C_1 + C_2$ be as in the figure below.

![Diagram](image)

We have $\mu^*(C_1 + C_2) = \tilde{C}_1 + \tilde{C}_2 + 6E_1 + 10E_2 + 18E_3 + 19E_4 + 38E_5 + 11E_6 + 22E_7$. The relevant positions are indicated by the black vertices: 3, 5 and 7. The jumping numbers of $a_1$ contributed by $E_3$ are $(5 + 6k)/12$, with $k \in \mathbb{N}$. But the three first jumping numbers of $a_1a_2$ are 5/18, 7/18 and 8/18. Hence the relevant values 7 and 8 are not among the relevant values of $a_1$ associated to the relevant position 3. Of course, the well known jumping numbers of the ideal $\mu_* \mathcal{O}_{\mathcal{Y}'}(-B_3)$ are $(2a + 3b)/6$, with $a$ and $b$ positive integers.

3 **The irregularity of the abelian covering of the projective plane**

In this section we state and prove in Theorem 3.3 a formula for the irregularity of the standard abelian coverings of the plane. To be able to express it, we start by summarizing the definition and some properties of these coverings in a form convenient for further use. Then, using the jumping walls in the context of plane curves, we introduce the notion of distinguished faces, leading notion in formula (7).
3.1 Abelian coverings

Let \( \pi : Y \to X = Y/G \) be a Galois covering with abelian Galois group \( G \). It is well known that \( \pi_* \mathcal{O}_Y \) is a coherent sheaf of \( \mathcal{O}_X \)-algebras and that \( Y \cong \text{Spec} \mathcal{O}_X(\pi_* \mathcal{O}_Y) \). In addition, if \( Y \) is normal and \( X \) is smooth, \( \pi \) is flat and consequently \( \pi_* \mathcal{O}_Y \) is locally free of rank \( n \).

The action of \( G \) on \( \pi_* \mathcal{O}_Y \) decomposes it into the direct sum of eigen line bundles associated to the characters \( \chi \in \hat{G} = \text{Hom}(G, S^1) \),

\[
\pi_* \mathcal{O}_Y = \mathcal{O}_X \oplus \bigoplus_{\chi \in \hat{G}, \chi \neq 1} \mathcal{L}_\chi^{-1}.
\]

The action of \( G \) on \( \mathcal{L}_\chi^{-1} \) is the multiplication by \( \chi \).

Let \( \chi_1, \ldots, \chi_s \in \hat{G} \) such that the group of characters is the direct sum of the cyclic subgroups generated by \( \chi_1, \ldots, \chi_s \). Let \( n_1, \ldots, n_s \) be their orders. In [19, Proposition 2.1] it is shown that the ring structure of \( \pi_* \mathcal{O}_Y \), and hence \( Y \), are determined by the following linear equivalences or isomorphisms. For every \( 1 \leq j \leq s \),

\[
n_j \mathcal{L}_{\chi_j} \sim \sum_{f \in \mathfrak{H}} \frac{n_j f(\chi_j)^*}{m_f} B_f,
\]

where: 1) the set \( \mathfrak{H} \) consists of all group epimorphisms from \( \hat{G} \) to different \( \mathbb{Z}/m \mathbb{Z} \); 2) the curve \( B_f \subset X \) with \( f \in \mathfrak{H} \) is the sub-divisor of the branch locus defined set-theoretically as \( \pi(R_f) \), with \( R_f \) the union of all the components \( D \) of the ramification locus associated to the group epimorphism \( f \); 3) the integer \( a^* \) denotes the smallest non-negative integer in the equivalence class \( a \in \mathbb{Z}/m \) (each time the integer \( m \) being understood from the context).

**Remark.** If \( D \) is a component of the ramification locus, since \( Y \) is normal and \( X \) smooth, \( D \) is 1-codimensional. The inertia subgroup \( H \subset G \) and a character \( \psi \in \hat{H} \)—the induced representation of \( H \) on the cotangent space to \( Y \) at \( D \)—that generates \( \hat{H} \) are associated to \( D \). Dualizing the inclusion \( H \subset G \), such a pair \((H, \psi)\) is equivalent to a group epimorphism \( f : \hat{G} \to \mathbb{Z}/m_f \), where \( m_f = |H| \).

Following [19], the line bundles \( \mathcal{L}_{\chi_j}, 1 \leq j \leq s \), and the divisors \( B_f, f \in \mathfrak{H} \), are called a set of reduced building data for the covering. In case \( X \) is compact, the covering is uniquely determined by the isomorphisms \( \mathfrak{H} \), up to isomorphisms of abelian coverings. It is to be noticed that if \( \chi = \chi_1^{a_1} \cdots \chi_s^{a_s} \in \hat{G} \), then

\[
\mathcal{L}_\chi \sim \sum_{j=1}^s a_j \mathcal{L}_{\chi_j} - \sum_{f \in \mathfrak{H}} \left( \sum_{j=1}^s \frac{a_j f(\chi_j)^*}{m_f} \right) B_f.
\]

So, to a normal covering \( \pi : Y \to X \) of a smooth variety \( X \), a set of reduced building data is associated satisfying the relations (3). Conversely, starting with a set of reduced building data and relations (3) an abelian covering is constructed which will be called a standard abelian covering.

**Notation 3.1.** In the sequel, we fix the notation \( S(n, M, C, H_\infty) \) for the abelian covering of the plane constructed as follows. Let \( C \subset \mathbb{P}^2 \) be a reduced curve and \( H_\infty \subset \mathbb{P}^2 \) a line called the line at infinity. The set of reduced building data consists of

8
the line bundles \( L_{\chi_j} = O_{\mathbb{P}^2}(\sum_{i=1}^t \mu_i^j d_i / n_j) \), 1 \( \leq j \leq s \),

- the line \( H_\infty \) and the curves \( C_i \subset C \) of degree \( d_i \), 1 \( \leq i \leq t \), such that \( C = \sum_i C_i \),
- the linear equivalences \( n_j L_{\chi_j} \sim \sum_{i=1}^t \mu_i^j C_i + ([\mu_j d_j / n_j] n_j - \mu_j d_j) H_\infty \), 1 \( \leq j \leq s \).

The covering \( S \to \mathbb{P}^2 \) thus obtained has Galois group \( \oplus_{j=1}^s \mathbb{Z}/n_j \mathbb{Z} \) and depends on the line at infinity and the \( r \times s \) matrix \( M = [\mu_j^1] \) with non negative integer entries. \( C \) is the list of curves \( (C_1, \ldots, C_t) \) and \( n \) the \( s \)-vector \( (n_1, \ldots, n_s) \) defining the covering group. The list of curves \( C \) such that \( C = \sum_i C_i \) will be referred to as a partition of \( C \).

**Remark 3.2.** In \( \Sigma \) the construction of the abelian coverings \( \Sigma_n \) that are studied is different from the one presented above. The construction is based on the composition of the Hurewicz epimorphism with the morphism given by the change of constants in the homology groups

\[
\pi_1(U) \to H_1(U, \mathbb{Z}) \to H_1(U, \mathbb{Z}/n\mathbb{Z}).
\]

Here \( U = \mathbb{P}^2 \setminus (C \cap H_\infty) = \mathbb{C}^2 \setminus C \), with \( C = \sum_{j=1}^s C_j \) the decomposition of \( C \) into irreducible components. It is known that there exists an exact sequence (see [3, Proposition 1.3])

\[
\mathbb{Z} i \to \bigoplus_{j=0}^s \mathbb{Z} \to H_1(U, \mathbb{Z}) \to 0
\]

with \( i(1) = g_0 + \sum_{j=1}^s d_j g_j \), \( g_0 = (1,0,\ldots) \) and so on. It follows that the epimorphism corresponds to a Galois unbranched covering \( V \to U \) with group \( H_1(U, \mathbb{Z}/n\mathbb{Z}) \simeq (\mathbb{Z}/n\mathbb{Z})^s \).

By the existence theorem of Grauert and Remmert [4], this covering extends to a unique normal abelian covering \( \pi : \Sigma_n \to \mathbb{P}^2 \), i.e., such that \( \pi^{-1}(U) = V \). It turns out that \( \Sigma_n \) is the normalization of the standard covering \( S((n, \ldots, n), I_s, C, H_\infty) \) introduced in Notation [3.1], i.e., for which the linear equivalences [3] are given by \( nL_{\chi_j} \sim C_j + ([d_j / n] n - d_j) H_\infty \).

### 3.2 Jumping walls and distinguished faces of a curve endowed with a partition

Let \( C \) be a reduced plane curve endowed with a partition \( C = (C_1, \ldots, C_t) \). Note that \( C = \sum_i C_i \). For each singular point of \( C \), we shall need to consider the mixed multiplier ideal \( \mathcal{J}(x \cdot C) = \mathcal{J}(x^1 C_1 + \ldots + x^t C_t) \) with \( x \) varying in the hypercube \([0,1]^t\). Interpreting the results of §[3] in this context, it follows that the jumping walls associated to these multiplier ideals cut up the hypercube into convex rational polytopes on which the map \( x \mapsto \mathcal{J}(x \cdot C) \) is constant. Note that the fibres of this map are neither open nor closed.

**Definition 3.3.** A face\(^3\) associated to \( C \) endowed with the partition \( C \) is a finite intersection of jumping walls and coordinate hyperplanes.

**Remark 3.4.** Even if we are interested in the jumping walls intersecting the hypercube, the context of rational divisors is not sufficient, since the jumping walls are determined by relevant values associated to ideal sheaves—more precisely, a jumping wall might intersect a coordinate axis in a jumping number bigger than 1 associated only to an ideal sheaf.

\[^3\text{In a previous version of the paper these faces were called walls and A. Libgober kindly pointed to me that using the word wall was misleading in codimension } \geq 2.\]
If $W$ is a face associated to a curve $C$ endowed with the partition $C$, the set $\mathcal{U}(W)$ is the set of the connected components of the difference between $W$ and the union of all the jumping walls and coordinate hyperplanes that do not contain $W$. The mixed multiplier ideal is constant on each $U \in \mathcal{U}(W)$ and will be denoted by $\mathcal{J}(U \cdot C)$. Furthermore, if $d$ is the vector $(d_1, \ldots, d_t)$, where deg $C_i = d_i$, we define the height function $h_C : \mathbb{R}^t \to \mathbb{R}$ by $h_C(x) = d \cdot x$.

Definition 3.5. A face $W$ of the projective curve $C$ endowed with the partition $C$ is called a distinguished face if the height function $h_C$ is constant on $W$. The set of distinguished faces will be denoted by $\mathcal{F}(C)$.

Lemma 3.6. If $C \subset \mathbb{P}^2$ is endowed with the partition $C$, $C_i$ is a component in $C$ and $W$ a distinguished face, then either $x^i = 0$ along $W$, or $C_i$ passes through $P$, a singular point of $C$, to which one of the jumping walls that cut out $W$ is associated.

Proof. It is easy to see that a distinguished face $W$, seen as a subset in the first orthant of $\mathbb{R}^t$, is bounded for the euclidean metric. Suppose that $W \not\subset \{x^i = 0\}$. Then the component $C_i$ must satisfy the conclusion since otherwise the corresponding coordinate $x^i$ would be unbounded. \hfill \Box

Example 3.7. Let $C_1, \ldots, C_6$ be the lines of Ceva’s arrangement $C = \bigcup C_i$; $C_i$ and $C_j$ intersect in a node of the arrangement if and only if $i + j = 7$. Ceva’s arrangement has four triple points: $C_4 \cap C_5 \cap C_6$, $C_1 \cap C_2 \cap C_4$, $C_2 \cap C_3 \cap C_6$ and $C_1 \cap C_3 \cap C_5$. For $C$ endowed with the partition $C = (C_1, \ldots, C_6)$ there are five distinguished faces: one for each triple point and one for all four. Clearly for each triple point $P$ there is a distinguished face $W_P$; for example if $P = C_4 \cap C_5 \cap C_6$ then $W_P$ is defined by $x^4 + x^5 + x^6 = 2$, $x^1 = x^2 = x^3 = 0$ and $h_C(W_P) = 2$. Now, if $W$ is a distinguished face different from the $W_P$, then let $\varphi_\alpha(x) = 2$ be the equations defining the jumping walls that cut out $W--2$ is the only relevant value. Note that each equation is of the form $x^i + x^j + x^k = 2$. Let $I \subset \{1, 2, \ldots, 6\}$ be the set of subscripts appearing in the equations $\varphi_\alpha$. Since $W$ is distinguished, $x^j = 0$ along $W$ for every $j \not\in I$. Furthermore the equation

$$\sum_{i \in I} x^i = h_C(W)$$

is a linear combination of the $\varphi_\alpha$. Hence there exist $\zeta_\alpha$ such that

$$\sum_\alpha \zeta_\alpha (\varphi_\alpha(x) - 2) = \sum_{i \in I} x^i - h_C(W)$$

for any $x \in \mathbb{R}^6$. Hence $2 \sum_\alpha \zeta_\alpha = h_C(W)$, and taking $x = 1$ for every $i \in I$, $3 \sum_\alpha \zeta_\alpha = |I|$. It follows that $2|I| = 3h_C(W)$, i.e. that $|I| = 6$ and $h_C(W) = 4$. To see that $W$ is unique with these properties it is sufficient to notice that $W$ is defined by the four equations corresponding to the four triple points. It is clear that it should be defined by at least three out of four equations. Summing these three equations and using $\sum_1^6 x^i = 4$ we get the fourth.
Example 3.8. Let $\Gamma_1$ and $\Gamma_2$ be two conics that have common tangents at the two points of intersection $P$ and $Q$. Let $H_\infty$ be the line through $P$ and $Q$. We want to determine the set of distinguished faces $\mathfrak{F}_d$ for the curve $C = C_1 + C_2$, with the partition $C = \{C_1, C_2\}$, where $C_1 = \Gamma_1 + \Gamma_2$ and $C_2 = H_\infty$. The curve $C_1$ has two tacnodes at $P$ and $Q$; a jumping number $3/4$ and hence a unique relevant value $3$. The curve $C = C_1 + C_2$ has two singular points and the exceptional configuration of the minimal log-resolution is $(2 + 1)E_1 + (4 + 1)E_2$. There are two jumping values, $3/5$ and $4/5$ and two relevant values $3$ and $4$ associated to the second exceptional divisor in the log-resolution for each singular point. It follows that there are two jumping walls $W_3$ and $W_4$ defined by $4x^1 + x^2 = 3$ and $4x^1 + x^2 = 4$ respectively. There are three faces and all three are distinguished since $h_C = 4x^1 + x^2$: $W_3$, $W_4$ and the intersection of $W_3$ with the coordinate line $\{x^2 = 0\}$, i.e. the point $W_0$ of coordinates $(3/4, 0)$. Finally,

$$U(W_0) = \{W_0\}, \quad U(W_3) = \{W_3 \smallsetminus W_0\} \quad \text{and} \quad U(W_4) = \{W_4\}.$$

3.3 The irregularity

In this section we state and prove the formula for the irregularity of the abelian covering $S' = S(n, M, C, H_\infty)$—the standard $\oplus_{j=1}^s \mathbb{Z}/n_j \mathbb{Z}$-covering $S' \to \mathbb{P}^2$ defined by the linear equivalences

$$n_jL_{\chi_j} \sim \sum_{i=1}^t \mu^j_i C_i + \left( \frac{1}{n_j} \sum_{i=1}^t \mu^j_i d_i \right) n_j - \sum_{i=1}^t \mu^j_i d_i) H_\infty,$$

where $\mathcal{L}_{\chi_j} = \mathcal{O}_{\mathbb{P}^2}(\sum_{i=1}^t \mu^j_i d_i/n_j)$, $d_i = \deg C_i$, $C = (C_1, \ldots, C_t)$, $n = (n_1, \ldots, n_s)$ and $M$ denotes the $t \times s$ matrix $[\mu^j_i]$ (see Notation [3.1]).

For any rational convex polytope $U \subset \mathbb{R}^t$ set

$$|U|_n^M = \text{card} \varphi^{-1}(U \cap [0, 1]^t),$$

where the map $\varphi : [0, 1]^s \cap \oplus_{j=1}^s 1/n_j \mathbb{Z} \to [0, 1]^t$, depending on $n = (n_1, \ldots, n_s)$ and the matrix $M$, is defined by

$$\varphi\left(\frac{a^1}{n_1}, \ldots, \frac{a^s}{n_s}\right) = \left(\left\langle \sum_j \mu^j \frac{a^j}{n_j}\right\rangle, \ldots, \left\langle \sum_j \mu^j \frac{a^j}{n_j}\right\rangle\right).$$

In case $M$ is the identity matrix we shall omit the superscript $M$ in the notation $|U|_n^M$. Similarly, if $n_j = n$ for every $j$, we shall use $|U|_n^M$ for $|U|_{(n, \ldots, n)}^M$. Note that $|U|_n^M$ is the number of rational points in $W$, points whose coordinates belong to $1/n\mathbb{Z}$ and are non-negative and smaller than $1$.

Theorem 3.9. Let $S$ be the normalization of the $\oplus_{j=1}^s \mathbb{Z}/n_j \mathbb{Z}$-abelian covering $S' \to \mathbb{P}^2$ with $S' = S(n, M, C, H_\infty)$. Suppose that $S$ is a connected surface. Then

$$q(S) = \sum_{W \in \mathfrak{F}(C)} \sum_{U \in U(W)} |U|_n^M \cdot h^1(\mathbb{P}^2, \mathcal{O}_{\mathbb{P}^2}(-3 + h_C(W)) \otimes J(U \cdot C)),$$

(7)
if \( \sum_i C_i \) is transverse to \( H_\infty \), and

\[
q(S) = \sum_{W \in \mathcal{G}(\mathcal{C})} \sum_{U \in \mathcal{U}(W)} [U_1 \cdots U_m] \cdot h^1(\mathbb{P}^2, O_{\mathbb{P}^2}(-3 + h_{\mathcal{C}}(W)) \otimes \mathcal{J}(U \cdot \mathcal{C})),
\]

(8)

if \( \sum_i C_i \) is not transverse to \( H_\infty \) and the covering is branched along \( H_\infty \), where \( \mathcal{C} = (H_\infty, C) \) and

\[
\mathcal{M} = \begin{bmatrix} \mu_0^1 & \cdots & \mu_0^s \end{bmatrix}
\]

with \( \mu_j^0 = \left[ \sum_{i=1}^t \frac{\mu_j^i d_i}{n_j} \right] n_j - \sum_{i=1}^t \mu_j^i d_i \).

**Proof.** In order to compute the irregularity of \( S \) we need to see \( S \) as a standard abelian covering of group \( \bigoplus_{j=1}^s \mathbb{Z}/n_j \mathbb{Z} \). We use the normalization algorithm from [19]. Let \( \mu : X \rightarrow \mathbb{P}^2 \) be a log resolution of the branch divisor. According to the position of the line at infinity, the points that are blown up lie either on \( \sum_i C_i \) or on \( \sum_i C_i + H_\infty \). The abelian covering \( S' \rightarrow \mathbb{P}^2 \) pulls back to a standard abelian covering \( S'' \rightarrow X \) defined by line bundles \( \mathcal{L}_{\chi_j}'' \).

Then, the normalization procedure yields the normal surface \( S \) with only Hirzebruch-Jung singularities.

\[
\begin{array}{ccc}
S & \longrightarrow & S'' \\
\downarrow \pi & & \downarrow \mu \\
X & \longrightarrow & \mathbb{P}^2
\end{array}
\]

It is a standard abelian covering with line bundles \( \mathcal{L}_{\chi_j}'' \) among the elements of the reduced building data. Using the Leray spectral sequence and the Serre duality,

\[
q(S) = h^1(S, O_S) = h^1(X, \pi_* O_S) = \sum_{\chi \in \mathcal{G}} h^1(X, \omega_X \otimes \mathcal{L}_{\chi}).
\]

For the computation of the terms in the right hand member, we distinguish two cases.

**First case.** \( H_\infty \) is transverse to \( \sum_i C_i \). Let

\[
\mu^* C_i = \tilde{C}_i + \sum_P e_i^P \cdot E_P
\]

the sum being taken over all the singular points of \( \sum_i C_i \) excepting the nodes. Here and in the sequel \( e_i^P \cdot E_P \) denotes the sum

\[
\sum_\alpha e_i^{P,\alpha} E_{P,\alpha}
\]

where \( E_{P,\alpha} \) are the irreducible components of the exceptional configuration of the log resolution \( \mu \) over \( P \). The line bundles \( L''_{\chi_j} \sim \left[ \sum_i \frac{\mu_j^i d_i}{n_j} \right] \tilde{H} \) and the linear equivalences

\[
n_j L''_{\chi_j} \sim \sum_i \frac{\mu_j^i \tilde{C}_i + \sum_{i,P} \mu_j^i e_i^P \cdot E_P}{n_j} + \left( \left[ \sum_i \frac{\mu_j^i d_i}{n_j} \right] n_j - \sum_i \mu_j^i d_i \right) \tilde{H}_\infty.
\]

12
holding for each $1 \leq j \leq s$, define $S''$. If $\chi = \chi_1^a \cdots \chi_s^a$, $0 \leq a_j < n_j$, then, after
normalization, by [17] Proposition 3.2 and by Proposition [13], $L_\chi$ is linearly equivalent to

$$
\sum_j a_j L''_\chi_j - \sum_i \left[ \sum_j \frac{a_j \mu_j^i}{n_j} \right] C_i - \sum_P \left[ \sum_{i,j} \frac{a_j \mu_j^i}{n_j} e_i^P \right] \cdot E_P
$$

$$
- \left[ \sum_{j=1}^s \frac{a_j}{n_j} \left( \sum_i \mu_j^i d_i / n_j \right) n_j - \sum_i \mu_j^i d_i \right] \tilde{H}_\infty,
$$

and using (9) and $\tilde{H}_\infty \sim \tilde{H}$ to

$$
\left( \left[ \sum_{i,j} \frac{a_j \mu_j^i d_i}{n_j} \right] - \sum_i \left[ \sum_j \frac{a_j \mu_j^i}{n_j} \right] d_i \right) \tilde{H} - \left( \sum_P \left[ \sum_i \frac{a_j \mu_j^i}{n_j} e_i^P \right] + \sum_{P,i} \left[ \sum_j \frac{a_j \mu_j^i}{n_j} \right] e_i^P \right) \cdot E_P.
$$

Setting

$$
x^i = \left\langle \sum_j \frac{a_j \mu_j^i}{n_j} \right\rangle \quad (10)
$$

for every $1 \leq i \leq t$, it follows that

$$
L_\chi \sim \left[ \sum_i d_i x^i \right] \tilde{H} - \sum_P \left[ \sum_i x^i e_i^P \right] \cdot E_P.
$$

Then

$$
h^1(X, K_X + L_\chi) = h^1(\mathbb{P}^2, \mathcal{O}_{\mathbb{P}^2}(-3 + \left[ \sum_i d_i x^i \right])) \otimes J(\sum_i x^i C_i) \quad (11)
$$

and the dimension $h^1(X, K_X + L_\chi)$ might be non-zero whenever the numbers $x^i$ satisfy three conditions. First $\sum_i x^i d_i$ must be an integer. If not, then the right-hand side of (11)
vanishes by the Kawamata-Viehweg-Nadel vanishing theorem. Second, for every curve $C_i$ there exists a singular point $P$ of $B$ lying on $C_i$ and a relevant position $\alpha$ of $P$ such that the number $\sum_i x^i e_i^{P,\alpha}$ is a relevant value of $D$ at $(P, \alpha)$. Indeed, if this condition does not hold for $C_1$ for example, it is sufficient to notice that $\mathcal{J}(D') = J(\sum_i x^i C_i)$, where $D' = (x^1 - \varepsilon)C_1 + \sum_{i=2}^t x^i C_i$ for $\varepsilon > 0$ sufficiently small, and to apply the Kawamata-
Viehweg-Nadel vanishing theorem to see that the right-hand side of (11) vanishes. Third, suppose that $\sum_i x^i d_i$ is an integer and that for every component $C_i$ there exists a singular
point $P$ of $B$ and a position $\alpha$ such that $r_{P,\alpha} = \sum_i x^i e_i^{P,\alpha}$ is a relevant value of $D$ at $(P, \alpha)$. If $W$ is the space of solutions of these equations seen as equations in the unknowns $x^i$, then $W$ is a face for the partition $C = (C_1, \ldots, C_t)$ and the linear operator $h_C : x \mapsto \sum_i x^i d_i$ must be constant on $W$. Indeed, if $W$ is positive dimensional and not contained into a fibre of $h_C$, it is sufficient to take $y \in W$ such that $\sum_i y^i d_i < \sum_i x^i d_i$. Then, if $\delta = \left[ \sum_i y^i d_i \right] = \sum_i x^i d_i$,

$$
h^1(\mathbb{P}^2, \mathcal{O}_X(-3 + \sum_i d_i x^i)) \otimes J(\sum_i x^i C_i) = h^1(\mathbb{P}^2, \mathcal{O}_X(-3 + \delta) \otimes J(\sum_i y^i C_i)) = 0.
$$

So the face $W$ is distinguished and $J(\sum_i x^i C_i) = J(U \cdot C)$, for $U$ the corresponding con-

connected components defined on $W$ by the other jumping walls and coordinate hyperplanes.
By the previous considerations we conclude that
\[
q(S) = \sum_{\chi \in G} h^1(X, K_X + L_{\chi})
\]
\[
= \sum_{W \in \mathcal{W}} \sum_{U \in \mathcal{U}(W)} |U|^M \cdot h^1(\mathbb{P}^2, \mathcal{O}_{\mathbb{P}^2}(-3 + h_C(W)) \otimes \mathcal{J}(U \cdot C)),
\]
where
\[
|U|^M = \text{card}\left\{(a^1, \ldots, a^s) \mid 0 \leq a^j < n_j, \left(\sum_j a^j \mu_j^1/n_j\right), \ldots, \left(\sum_j a^j \mu_j^s/n_j\right) \in U\right\}.
\]

Second case. If $H_\infty$ is not transverse to $\sum_i C_i$ and $S'$ is ramified above $H_\infty$, then, supposing for simplicity that there is only one singular point $Q$ of $\sum_i C_i$ lying on $H_\infty$, we have
\[
\mu_s^*(\sum_i C_i + H_\infty) = \sum_i \tilde{C}_i + \tilde{H}_\infty + \sum_{p \neq Q} e^p \cdot E_p + (e_Q + e_Q^\infty) \cdot E_Q,
\]
with $e^p = \sum_i e^p_i$ and $e_Q^\infty = (1, \ldots)$. As in the first case,
\[
n_j L'_{\chi \jmath} \sim \sum_i \mu^i_j \tilde{C}_i + \sum_i \mu^i_j e^p_i \cdot E_p + \left(\sum_i \mu^i_j d_i/n_j \right) n_j - \sum_i \mu^i_j d_i \right) \tilde{H}_\infty \]
\[
+ \left(\sum_i \mu^i_j d_i/n_j \right) n_j - \sum_i \mu^i_j d_i \right) e_Q^\infty \cdot E_Q,
\]
hence
\[
L'_{\chi \jmath} \sim \left(\sum_i \frac{a^j \mu^j_i}{n_j} d_i \right) \tilde{H}_\infty - \left(\sum_i \frac{a^j \mu^j_i}{n_j} d_i \right) e_Q \]
\[
+ \sum_{p \neq Q} \left(\sum_{i,j} \frac{a^j \mu^j_i}{n_j} e^p_i \cdot E_p - \sum_{i,j} \frac{a^j \mu^j_i}{n_j} e^p_i \cdot E_p + \sum_{j=1}^s \frac{a^j}{n_j} \left(\sum_i \frac{a^j \mu^j_i}{n_j} d_i \right) n_j - \sum_i \frac{a^j \mu^j_i}{n_j} d_i \right) e_Q^\infty \cdot E_Q.
\]
By (H) and $\tilde{H}_\infty \sim \tilde{H} - e_Q^\infty \cdot E_Q$,
\[
L_{\chi \jmath} \sim \left(\sum_{i,j} \frac{a^j \mu^j_i}{n_j} d_i \right) \tilde{H}_\infty
\]
\[
- \sum_{p \neq Q} \left(\sum_{i,j} \frac{a^j \mu^j_i}{n_j} e^p_i \cdot E_p - \sum_{p,i} \left(\sum_{j} \frac{a^j \mu^j_i}{n_j} e^p_i \right) \right) \cdot E_p
\]
\[
- \left(\sum_{i,j} \frac{a^j \mu^j_i}{n_j} e_Q^\infty - \sum_{i,j} \frac{a^j \mu^j_i}{n_j} e_Q^\infty \right) - \sum_{i,j} \left(\sum_{j} \frac{a^j \mu^j_i}{n_j} e_Q^\infty \right) e_Q^\infty + \left(\sum_{i,j} \frac{a^j \mu^j_i}{n_j} d_i \right) e_Q^\infty \cdot E_Q.
\]
Set \( x^i = \left\langle \sum_j a^j \mu^j_i / n_j \right\rangle \), \( 1 \leq i \leq t \), as in (10). Then

\[
L_\chi \sim \left[ \sum_{i=1}^t d_i x^i \right] \tilde{H} - \sum_{P \neq Q} \left[ \sum_{i=1}^t x^i e^P_i \right] \cdot E_P - \left( \sum_{i=1}^t x^i e^Q_i - \sum_{i=1}^t d_i x^i e^Q_\infty \right) + \left[ \sum_{i=1}^t d_i x^i \right] e^Q_\infty \cdot E_Q. \tag{12}
\]

In the formula for the irregularity, two things may happen. Either \( \sum_i d_i x^i \) is an integer and the superabundances involved can be dealt with as before, or \( \sum_i d_i x^i \) is not an integer. In this latter situation set \( C_0 = H_\infty, \ d_0 = 1, \ e^P_0 = 0 \) if \( P \neq Q \) and

\[
x^0 = \left\lfloor \sum_i d_i x^i \right\rfloor - \sum_i d^s x_i.
\]

Then

\[
L_\chi \sim \left( x^0 + \sum_{i=1}^t d_i x^i \right) \tilde{H} - \sum_{P \neq Q} \left[ \sum_{i=1}^t x^i e^P_i \right] \cdot E_P - \left( x^0 e^Q_0 + \sum_{i=1}^t x^i e^Q_i \right) \cdot E_Q
\]

and the formula for the irregularity follows as before replacing \( \sum_{i=1}^t C_i \) by \( \sum_{i=0}^t C_i \), \( C \) by \( \overline{C} = (C_0, \ldots, C_t) \) and \( M \) by \( \overline{M} \), where

\[
\overline{M} = \begin{bmatrix} \mu^0_0 & \cdots & \mu^0_s \\ M \end{bmatrix}
\]

with \( \mu^0_j = \left[ \sum_{i=1}^t \mu^j_i d_i / n_j \right] n_j - \sum_{i=1}^t \mu^j_i d_i \). To end the proof it remains to show that

\[
x^0 = \left\langle \sum_j a^j \mu^0_j / n_j \right\rangle.
\]

But this is clear, since

\[
\left\langle \sum_j a^j \mu^0_j / n_j \right\rangle = \left\langle \sum_j \left( \frac{1}{n_j} \sum_{i=1}^t \mu^j_i d_i \right) n_j - \left( \sum_{i=1}^t \mu^j_i d_i \right) a^j / n_j \right\rangle
\]

\[
= \left\langle \sum_{i,j} d_i a^j \mu^j_i / n_j \right\rangle - \sum_{i,j} d_i a^j \mu^j_i / n_j
\]

\[
= \left[ \sum_{i=1}^t d_i \left\langle \sum_{j=1}^s a^j \mu^j_i / n_j \right\rangle \right] - \sum_{i=1}^t d_i \left\langle \sum_{j=1}^s a^j \mu^j_i / n_j \right\rangle
\]

and this equals \( x^0 \) by the definition of the \( x^i \) when \( 1 \leq i \leq t \). \( \square \)
4 Applications and examples

4.1 Asymptotic behaviour of the irregularity

In setting out to look for applications of Theorem 3.9 it seems best to start with the asymptotic behaviour of the irregularity of the abelian coverings of the projective plane described by E. Hironaka in [6].

Corollary 4.1. Let \( S' \to \mathbb{P}^2 \) be the \((\mathbb{Z}/n\mathbb{Z})^s\)-abelian covering defined by \( L_{\chi_j} \sim C_j + ([d_j/n] n - d_j)H_\infty \), \( 1 \leq j \leq s \), with \( d_j = \deg C_j \). If \( S \) is the normalization of \( S' \), then

\[
q(S) = \sum_{W \in \mathfrak{F}(C)} \sum_{U \in \mathcal{U}(W)} |U|_n \cdot h^1 \left( \mathbb{P}^2, \mathcal{O}_{\mathbb{P}^2}(-3 + h_C(W)) \otimes J(U \cdot C) \right)
\]

where the partition \( C \) is given either by the curves \( C_1, \ldots, C_s \) or by the curves \( H_\infty, C_1, \ldots, C_s \), depending on whether or not \( H_\infty \) is transverse to \( \sum_i C_i \).

Proof. By Theorem 3.9, when \( \sum_i C_i \) is not transverse to \( H_\infty \) and the covering is branched along \( H_\infty \),

\[
q(S) = \sum_{W \in \mathfrak{F}(\overline{C})} \sum_{U \in \mathcal{U}(W)} |U|_n^{\overline{M}} \cdot h^1 \left( \mathbb{P}^2, \mathcal{O}_{\mathbb{P}^2}(-3 + h_{\overline{C}}(W)) \otimes J(U \cdot \overline{C}) \right),
\]

where \( \overline{C} = (H_\infty, C) \) and \( \overline{M} = \begin{bmatrix} \mu_1^0 & \cdots & \mu_s^0 \\ & \ddots & \\ & & \mu_s^0 \end{bmatrix} \), with \( \mu_j^0 = [d_j/n] n - d_j \) for \( 1 \leq j \leq s \).

Moreover, \( |U|_n^{\overline{M}} = \text{card} \varphi^{-1}(U \cap [0, 1)^{s+1}) \), where the map \( \varphi : [0, 1)^s \cap (1/n\mathbb{Z})^s \to [0, 1)^{s+1} \)

associated to \( \overline{M} \) is defined by

\[
\varphi \left( \frac{a_1}{n_1}, \ldots, \frac{a_s}{n_s} \right) = \left( \sum_j \mu_j^0 \frac{a_j}{n_j}, \frac{a_1}{n}, \ldots, \frac{a_s}{n} \right).
\]

Since \( \varphi \) is injective, it follows that

\[
|U|_n^{\overline{M}} = \text{card}(U \cap [0, 1)^{s+1} \cap (1/n\mathbb{Z})^{s+1}) = |U|_n.
\]

□

Using Corollary 4.1 we can recover E. Hironaka’s result concerning the asymptotic behaviour of the irregularity of the abelian covering \( \Sigma_n \). See also [4, Theorem 1.7], where N. Budur establish the quasi-polynomial behaviour of the Hodge numbers \( h^{0,q} \) of the finite abelian coverings of a smooth \( n \)-dimensional variety.

Corollary 4.2. Let \( C \subset \mathbb{P}^2 \) be a reduced curve and \( \Omega = \mathbb{P}^2 \setminus (C \cup H_\infty) \). Let \( \Sigma_n \) be the unique normal abelian covering associated to the natural epimorphism

\[
\pi_1(\Omega) \twoheadrightarrow H_1(\Omega, \mathbb{Z}) \rightarrow H_1(\Omega, \mathbb{Z}/n\mathbb{Z}) \cong (\mathbb{Z}/n\mathbb{Z})^s,
\]

with \( s \) the number of connected components of \( C \). Then \( q(\Sigma_n) \) is a quasi-polynomial function of \( n \) of degree \( \leq s \).
Definition. A function \( f : \mathbb{N} \to \mathbb{N} \) is called a quasi-polynomial function if there exists an integer \( N > 0 \) and polynomials \( P_0, \ldots, P_{N-1} \) such that \( f(n) = P_j(n) \) if \( n \equiv j \mod N \).

Proof. By Remark 3.2, the surface \( \Sigma_n \) coincides with the normalization of the abelian covering of the projective plane with group \( (\mathbb{Z}/n\mathbb{Z})^s \), associated to \( C = \sum_{j=1}^{s} C_j \) and \( H_\infty \) and determined by
\[
 nL_j \sim C_j + ([d_j/n] n - d_j)H_\infty.
\]
By Corollary 4.1 we have
\[
 q(\Sigma_n) = \sum_{W \in \mathfrak{B}(C) \cup U(W)} |U| \cdot h^1(\mathbb{P}^2, \mathcal{O}_{\mathbb{P}^2}(-3 + h_C(W)) \otimes J(U \cdot C)),
\]
with \( C \) the partition of \( C \) induced by the curves \( C_j \). The closure of the subset \( U \subset W \) in \( W \) represents a convex polytope and its border in \( W \) a finite union of convex polytopes.

Now, if \( \mathcal{P} \subset \mathbb{R}^s \) is a convex polytope, the Ehrhart quasi-polynomial of \( \mathcal{P} \) is the function defined by
\[
 i(\mathcal{P}, n) = \text{card}(n\mathcal{P} \cap \mathbb{Z}^s),
\]
where \( n\mathcal{P} = \{nx \mid x \in \mathcal{P}\} \). Clearly, the number \( i(\mathcal{P}, n) \) is equal to the number of rational points in \( \mathcal{P} \cap (1/n\mathbb{Z})^s \). We refer the reader to [21, Theorem 4.6.25] where it is shown that \( i(\mathcal{P}, n) \) is indeed a quasi-polynomial whose degree is \( \dim \mathcal{P} \). The result follows. \( \square \)

4.2 Cyclic coverings

As a particular case of Theorem 3.9 we obtain the formula for the irregularity of cyclic multiple planes. This study has been initiated by O. Zariski in [23] where he computed the irregularity in case the branching curve has only nodes and cusps as singularities. Various generalizations have since been proposed to Zariski’s formula in [3, 12, 13, 16, 22, 17].

Corollary 4.3. Let \( C \subset \mathbb{P}^2 \) be a curve of degree \( d \) and \( H_\infty \) a line transverse to \( C \).
If \( S_n \) is the normalization of the standard cyclic \( \mathbb{Z}/n\mathbb{Z} \)-covering of the plane defined by the linear equivalence \( nL_\chi \sim C + ([d/n] n - d)H_\infty \), then
\[
 q(S_n) = \sum_{\xi \text{ jumping number of } C, \xi \in 1/(n\mathbb{Z} / \mathbb{Z})} h^1(\mathbb{P}^2, \mathcal{O}_{\mathbb{P}^2}(-3 + \xi d) \otimes J(\xi \cdot C)).
\]

Proof. Since \( H_\infty \) is transverse to \( C \), then the faces in the formula (17) are points \( \xi \) in the open interval \( (0, 1) \) corresponding to the jumping numbers of \( C \) such that \( \xi \cdot \deg C \in \mathbb{Z} \).
Moreover \( |\xi|_n = \text{card}\{\xi \} \cap 1/n\mathbb{Z} \) equals 1 or 0 depending on weather \( \xi n \in \mathbb{Z} \). The result follows. \( \square \)

In the case of a cyclic covering, if \( H_\infty \) is not transverse to \( C \), then the faces in the formula (18) live in \( \mathbb{R}^2 \) with euclidean coordinates \( x \) and \( x_\infty \). They are of two types: 1) those for which \( x_\infty = 0 \), in which case they are jumping numbers for \( C \) and the corresponding term in (18) is determined as in the above corollary; 2) those for which \( x_\infty \neq 0 \) and the face is determined by an equation whose homogeneous part must coincide with the linear form \( h_{(H_\infty, C)} \) modulo the multiplication by a non-zero rational. It may be said that the results obtained for the irregularity are qualitatively different. In the transverse situation the
irregularity is constant as a function of $n$. In the non transverse situation the irregularity depends on $n$. More precisely, using Hironaka’s result, it is a quasi-polynomial of degree $\leq 1$. The next example illustrates this behaviour of the irregularity in the non transverse situation.

**Example 4.4.** The two ellipses $\Gamma_i$, $i = 1, 2$, with common tangents at $P$ and $Q$ considered in Example 3.3 provide cyclic coverings with maximal degrees for the quasi-polynomials that represent the irregularity, whatever the relative position of the line at infinity.

If $H_\infty$ is transverse to $B = \Gamma_1 + \Gamma_2$, then the $\mathbb{Z}/n\mathbb{Z}$-cyclic covering $S_n$ has non vanishing irregularity if and only if $n$ is divisible by 4, since $3/4$ is the only jumping number of $B$, in which case

$$q(S_n) = h^1(\mathbb{P}^2, \mathcal{I}_{P,Q}) = 1.$$ 

Now, if $H_\infty$ is the line through $P$ and $Q$, then we have seen in Example 3.3 that there are two jumping walls $W_3$ and $W_4$, and three distinguished faces, the previous two and the point $W_0$, the intersection of $W_3$ with the coordinate plane $x^\infty = 0$. Set $C = \Gamma_1 + \Gamma_2 + H_\infty$. By Corollary 4.1, we get, for $n \geq 4$,

$$q(S_n) = |W_0|_n h^1(\mathbb{P}^2, \mathcal{J}(W_0 \cdot C)) + |W_3 \setminus W_0|_n h^1(\mathbb{P}^2, \mathcal{J}(W_3 \setminus W_0 \cdot C)) + |W_4|_n h^1(\mathbb{P}^2, \mathcal{O}(1) \otimes \mathcal{J}(W_4 \cdot C)) = |W_0|_n h^1(\mathbb{P}^2, \mathcal{I}_{P,Q}) + |W_3 \setminus W_0|_n h^1(\mathbb{P}^2, \mathcal{I}_{P,Q}) + |W_4|_n h^1(\mathbb{P}^2, \mathcal{I}_{Z}(1)) = |W_3|_n h^1(\mathbb{P}^2, \mathcal{I}_{P,Q}) + |W_4|_n h^1(\mathbb{P}^2, \mathcal{I}_{Z}(1)),$$

where $Z$ is the subscheme supported at $P$ and $Q$ and determined by the points and the directions of the tangents to the two conics at $P$ and $Q$. Since

$$|W_l|_n = \text{card}\{(x, x^\infty) \mid 4x + x^\infty = l, 0 \leq x < 1, 0 \leq x^\infty < 1, x, x^\infty \in 1/n\mathbb{Z}\},$$

$l = 3, 4$, it follows that

$$q(S_n) = \left\lfloor \frac{n+1}{4} \right\rfloor + \left\lfloor \frac{n+3}{4} \right\rfloor.$$

**Example 4.5.** If in the previous example we consider the abelian covering $\Sigma_n$ of $\mathbb{P}^2$ with group $\mathbb{Z}/n\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z}$ and branched along $C = \Gamma_1 + \Gamma_2 + H_\infty$ with the partition $C = (\Gamma_1, \Gamma_2, H_\infty)$, then the formula for the irregularity is the same but the faces are defined in $\mathbb{R}^3$ by

$$W_l = \{(x^1, x^2, x^\infty) \mid 2x^1 + 2x^2 + x^\infty = l\},$$

$l = 3, 4$. Then

$$|W_3|_n = \frac{1}{2} \left\lfloor \frac{n}{2} \right\rfloor \left( n + \left\lfloor \frac{n}{2} \right\rfloor - 3 \right)$$

and

$$|W_4|_n = \frac{1}{2} \left\lfloor \frac{n-1}{2} \right\rfloor \left( \left\lfloor \frac{n-1}{2} \right\rfloor - 1 \right),$$

hence $q(\Sigma_n) = (n-1)(n-2)/2$.

\footnote{For $n = 4$ the covering is branched only along the two conics and the irregularity equals 1. For $n = 3$, the formula for the non transverse intersection applies and the irregularity equals 2. For $n = 2$ the covering is branched again only along the conics and $q = 0$.}
4.3 Line arrangements with only triple points

Next we want to point out that the formula \((\ref{eq:formula})\) simplifies in case the branching curve is a line arrangement \(A\) with only triple points.

**Notation.** Let \(W\) be a face. The subarrangement \(A_W\) will denote the minimal subarrangement of \(A\) determined by the points that contribute to \(W\). This subarrangement is unique since all points are triple points.

**Theorem 4.6.** Let \(A = \bigcup_{j=1}^{m} H_j\) be a line arrangement in the projective plane and let \(H_\infty\) be a line either of \(A\) or transverse to \(A\). Let \(s = m - 1\) in the former case and \(s = m\) in the latter. If \(S\) is the normalization of the standard abelian covering associated to \(A\), the line \(H_\infty\) and the group \(G \simeq (\mathbb{Z}/n\mathbb{Z})^s\), then

\[
q(S) = \sum_{W \in \mathfrak{S}(A)} \sum_{U \in \mathcal{U}(W)} |U| \cdot h^1(\mathbb{P}^2, \mathcal{O}_{\mathbb{P}^2}(-3 + 2/3 \deg A_W) \otimes \mathcal{I}_U). \tag{14}
\]

**Proof.** For each singular point \(P\) of the arrangement, the configuration of exceptional divisors is reduced to only one divisor \(E_P\), with \(e^A_P = 3\). Moreover, \(e^P_j = 1\) or \(0\) depending on whether the line \(H_j\) passes through \(P\) or not. Since 2/3 is the only jumping number smaller than 1 for a triple point, the only relevant value is 2. It follows that for any \(P\), the elementary wall \(W_P\) is given by

\[
W_P = \{(x^1, \ldots, x^s) \mid e^1_P x^1 + \ldots + e^s_P x^s = 2\}.
\]

Now, let \(W\) be a bounded face in the formula for the irregularity. There exists a unique minimal subarrangement \(A_W\) determined by the points contributing to \(W\).

**Claim.** \(h_A(W) = 2/3 \deg(A_W)\).

Indeed, let \(I \subset \{1, \ldots, s\}\) such that \(A_W = \bigcup_{i \in I} H_i\). Since \(h_A\) is constant along \(W\), the equation \(\sum_{i \in I} x^i = h_A(W)\) is a linear combination of the equations defining \(W\) in \([0, 1)^{|I|}\). Using this linear combination on the free term and also evaluated for \(x^i = 1\) for every \(i \in I\), the result follows.

To end the proof of the theorem, it is sufficient, for any \(U \in \mathcal{U}(W)\), to consider the subscheme \(Z_U\) of points \(P\) that are among the triple points of \(A_W\) and for which \(\sum_{i \in I} e^i_P x^i = 2\).

**Example 4.7 (The Ceva arrangement \(A_1(6)\)).** Let \(A\) be the Ceva arrangement of degree 6 with three double points and four triple points. Let \(S\) be the normalisation of the abelian covering of \(\mathbb{P}^2\) branched along \(A\) with \(H_\infty \subset A\) and group \((\mathbb{Z}/n\mathbb{Z})^5\). Then

\[
q(S) = \frac{5(n-2)(n-1)}{2}.
\]

These surfaces are introduced by F. Hirzebruch in \([7]\). If \(n = 5\), the irregularity was computed by M.-N. Ishida in \([8]\). The general case was dealt with by A. Libgober in \([14]\).

The sub-arrangements that may have a non-zero contribution in the formula \((\ref{eq:formula})\) are either the pencil sub-arrangement \(A_P\) of a triple point \(P\), or the arrangement \(A\). Now,

\[
h^1(\mathbb{P}^2, \mathcal{O}_{\mathbb{P}^2}(-3 + 2/3 \deg A_P) \otimes \mathcal{I}(2/3 \cdot A_P)) = h^1(\mathbb{P}^2, \mathcal{I}_P(-1)) = 1
\]
and, if $Z$ denotes the support of the triple points,
\[
h^1\left(\mathbb{P}^2, \mathcal{O}_{\mathbb{P}^2}(-3 + 2/3 \deg \mathcal{A}) \otimes \mathcal{J}(2/3 \cdot \mathcal{A})\right) = h^1\left(\mathbb{P}^2, \mathcal{I}_Z(1)\right) = 1.
\]
So,
\[
q(S) = \sum_P |W(\mathcal{A}_P)| \cdot h^1(\mathbb{P}^2, \mathcal{I}_P(-1)) + |W(\mathcal{A})| \cdot h^1(\mathbb{P}^2, \mathcal{I}_Z(1))
= \sum_P |W(\mathcal{A}_P)| + |W(\mathcal{A})|.
\]

$|W(\mathcal{A}_P)|$ counts in how many ways $2n$ can be written as a sum of three integers that vary in \{0, 1, ..., $n-1$\}. Let us denote this integer by $\sigma_3(2n)$. It follows that $|W(\mathcal{A}_P)| = \sigma_3(2n) = (n-2)(n-1)/2$. As for $|W(\mathcal{A})|$, it counts the number of solutions of
\[
\frac{1}{n} \sum_{j=1}^{6} a^j = 4 \quad \text{and} \quad \frac{1}{n} \sum_{H_i \cap P} a^j = 2 \quad \text{for every } P.
\]
This means that $a^1 + a^2 + a^3 = 2n$ and that $a^i = a^j$ if and only if the lines $H_i$ and $H_j$ intersect in a double point of $\mathcal{A}$. Hence $|W(\mathcal{A})| = \sigma_3(2n)$. The result follows.

4.4 The arrangement dual to the arrangement defined by the inflexion points of a smooth cubic

Another arrangement considered in [4] is the dual to the arrangement defined by the inflexion points of a smooth cubic. Let $\mathcal{A}$ be such an arrangement. It has degree 9 and twelve triple points as only singularities. In particular, each line contains four triple points.

**Proposition 4.8.** Let $S$ the normalization of the abelian covering of $\mathbb{P}^2$ branched along $\mathcal{A}$ with $H_\infty \subset \mathcal{A}$ and group $\mathbb{Z}/n\mathbb{Z})^8$. Then $q(S) = 8(n-1)(n-2) - 2\delta_{0}^n \mod 3$, where $\delta_{i}^j$ denotes the Kronecker symbol.

**Remark.** The case $n = 5$ is treated in [9] and the general case in [14]. In this latter paper the formula for the irregularity is $8(n-1)(n-2)$, lacking the corrective term in case $n$ is divisible by 3.

**Proof.** By Theorem 4.6 we have to study faces for which the degree of the corresponding subarrangement $\mathcal{A}_W$ is divisible by 3, i.e. equals 3, 6 or 9. In the first case, $\mathcal{A}_W$ is a pencil subarrangement with a single triple point. It will be denoted $\mathcal{A}_P$, with $P$ the triple point. If $\sigma_3(2n)$ is as before the number of ways $2n$ can be written as a sum of three integers from the set \{0, 1, ..., $n-1$\}, then
\[
\sum_P |W(\mathcal{A}_P)| \cdot h^1(\mathbb{P}^2, \mathcal{I}_P(-1)) = 12\sigma_3(2n).
\]

In the second case, $\mathcal{A}_W$ is a Ceva subarrangement and it is easy to see that such a subarrangement cannot exist. As for the last case, there are different faces $W$ such that $\mathcal{A}_W = \mathcal{A}$. Let $W$ be determined by nine points among the twelve triple points—at least nine points are needed so that the corresponding $h^1$ might be non zero. Since any ten among
the twelve points impose independent conditions on cubics as soon as the two remaining points lie on a line of the arrangement, we infer that $W$ is determined by nine points such that there is no line of the arrangement containing any two of the remaining three points. Hence, through each of these three points pass three lines of the arrangement. Now, if $Z$ is the union of the nine points that determine $W$, then $h^1(\mathbb{P}^2, I_Z(3)) = 1$. If $H_1$, $H_2$ and $H_3$ are the three lines through one of the triple points not in $Z$, then summing up the conditions for the points of $Z$ lying on each of these three lines, we obtain that

$$6n = 3a^1 + \sum_{j=4}^9 a^j = 3a^2 + \sum_{j=4}^9 a^j = 3a^3 + \sum_{j=4}^9 a^j.$$ 

Hence $a^j$ is constant for the lines passing through each of the three missing points. Let $a(W)$, $a'(W)$ and $a''(W)$ be these three constant values. By the preceding equalities,

$$a(W) + a'(W) + a''(W) = 2n. \tag{15}$$

It follows that

$$q(S) = \sum_P |W(A_P)| \cdot h^1(\mathbb{P}^2, I_P(-1)) + \sum_{W \text{ given by 9 points}} \sum_{U \in \mathcal{U}(W)} |U| \cdot h^1(\mathbb{P}^2, J(U \cdot \mathcal{A})(3))$$

$$+ \sum_{W \text{ given by 10 points}} \sum_{U \in \mathcal{U}(W)} |U| \cdot h^1(\mathbb{P}^2, J(U \cdot \mathcal{A})(3)) + |W(\mathcal{A})| \cdot h^1(\mathbb{P}^2, J(2/3 \cdot \mathcal{A})(3),$$

since if a face is defined by eleven points, using $[3]$, it will be defined by all twelve in fact. Moreover, in the two middle sums, $h^1(\mathbb{P}^2, J(U \cdot \mathcal{A})(3)) = h^1(\mathbb{P}^2, I_{Z(U)}(3)) = 1$. Indeed, if $U \in \mathcal{U}(W)$ and $W$ is defined by a set $Z$ of nine triple points as above, the subscheme $Z(U)$ is the union of $Z$ and of either one or two more points, depending on the comparison of $3a(W)$, $3a'(W)$ and $3a''(W)$ with $2n$.

In the hereafter lemma it is shown that $h^1(\mathbb{P}^2, J(2/3 \cdot \mathcal{A})(3)) = 2$. From the preceding considerations and since there are exactly four groups of three points such that there is no line of the arrangement containing any two among the three points,

$$\sum_{W \text{ given by 9 points}} \sum_{U \in \mathcal{U}(W)} |U| \cdot h^1(\mathbb{P}^2, I_{Z(U)}(3)) + \sum_{W \text{ given by 10 points}} \sum_{U \in \mathcal{U}(W)} |U| \cdot h^1(\mathbb{P}^2, I_{Z(U)}(3))$$

$$= \sum_{W \text{ given by 10 points}} (|W| - \delta^0_{n \mod 3}|W(\mathcal{A})|) = 4(\sigma_3(2n) - \delta^0_{n \mod 3}).$$

The corrective term $\delta^0_{n \mod 3}$ is given by the fact that if $n$ is divisible by 3, then the point in $W$ corresponding to the case $a(W) = a'(W) = a''(W) = 2n/3$ is to be considered in the face $W(\mathcal{A})$. We conclude that

$$q(S) = 12\sigma_3(2n) + 4(\sigma_3(2n) - \delta^0_{n \mod 3}) + 2\delta^0_{n \mod 3} = 8(n - 1)(n - 2) - 2\delta^0_{n \mod 3}.$$
**Lemma 4.9.** \( h^1(\mathbb{P}^2, \mathcal{I}(2/3 \cdot \mathcal{A})) = 2. \)

**Proof.** Let \( Z \) denotes the twelve triple points of \( \mathcal{A} \). We apply the trace-residual exact sequence to the three lines \( H_1, H_2 \) and \( H_3 \) that pass through one of the triple points. Let \( P \) and \( P' \) be the points not lying on these lines. The exact sequences are

\[
0 \to I_{\text{Res}H_1Z}(2) \to I_{\text{Res}H_1Z}(3) \to \mathcal{O}_{\mathbb{P}^1}(-1) \to 0,
\]

and

\[
0 \to I_{\text{Res}H_2(\text{Res}H_1Z)}(1) \to I_{\text{Res}H_1Z}(2) \to \mathcal{O}_{\mathbb{P}^1}(-1) \to 0,
\]

since \( \text{deg Res}_{H_2(\text{Res}H_1Z)} = 3 \) and \( \text{Res}_{H_3}(\text{Res}H_1Z) = P \cup P' \).

It follows that

\[
h^1(\mathbb{P}^2, \mathcal{I}_Z(3)) = h^1(\mathbb{P}^2, I_{\text{Res}H_2(\text{Res}H_1Z)}(1)) = h^1(\mathbb{P}^2, I_{P+P'}) + h^2(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}(-2)) = 2.
\]

\( \square \)

### 4.5 The arrangement associated to the Hesse pencil

Let \( \mathcal{A} \) be the line arrangement associated to the Hesse pencil. It is composed by the lines of the four singular fibres of the pencil generated by a smooth elliptic curve and its Hessian. It has degree 12, and twelve double points and nine quadruple points as singularities. The double points correspond to intersection points of lines from the same singular fibre.

**Proposition 4.10.** Let \( S \) the normalization of the abelian covering of \( \mathbb{P}^2 \) branched along \( \mathcal{A} \) with \( H_{\infty} \subset \mathcal{A} \) and group \((\mathbb{Z}/n\mathbb{Z})^{11}\). Then

\[
q(S) = \frac{(n-1)(61n^2 + 97n - 378)}{6}.
\]

**Proof.** Theorem 3.9 must be used here. The relevant values for each singular point of \( \mathcal{A} \) are 2 and 3. The distinguished faces appearing in the formula for the irregularity are of the following types:

1) \( W_P \) associated to \( (P, 2) \) for each singular point \( P \). The corresponding term in the right hand member of (3) equals \( \sigma_4(2n) \) since the conditions are

\[
\frac{1}{n} \sum_{j=1}^{12} a^j = 2 \quad \text{and} \quad \frac{1}{n} \sum_{H_j \ni P} a^j = 2.
\]

2) \( W_P \) associated to \( (P, 3) \) for each singular point \( P \). Here the corresponding term equals \( \sigma_4(3n) \).

3) \( W_B \), with \( B \) a Ceva subarrangement. The face \( W_B \) is associated to the singular points of \( B \) seen in \( \mathcal{A} \), with relevant value 2 for each one of them. There are 54 such subarrangements, one for each choice of two fibers and two by two components in each fiber—such a choice determines the four triple points of \( B \). As for the terms corresponding to \( W_B \) in the formula for the irregularity, let \( H_1, \ldots, H_6 \) be the lines of \( B \) and let \( H_7, \ldots, H_{10} \) be the remaining lines through its triple points. Furthermore we suppose that \( H_i \) and \( H_j \)
intersect in a double point if and only if \( i + j = 7 \). The defining conditions of \( W_B \) are the four equalities corresponding to the triple points:

\[
\frac{1}{n}(a^1 + a^2 + a^3 + a^7) = 2 \quad \text{and so on, plus} \quad a^{11} = a^{12} = 0.
\]

The corresponding cohomology group in the formula (7) is non trivial if and only if \( h_A(W_B) = \sum_{j=1}^{10} a^j / n = 4 \). Summing these four conditions for the four points, we get

\[
2 \sum_{j=1}^{6} a^j + \sum_{k=7}^{10} a^k = 8n.
\]

We conclude that \( W_B \) must be defined by \( a^7 = \cdots = a^{12} = 0, a^1 = a^6, a^2 = a^5 \) and \( a^3 = a^4 \), and \( a^1 + a^2 + a^3 = 2n \). Hence \( |W_B| = \sigma_3(2n) \).

4) \( W \) defined by all nine singular points: six with relevant value 2, and the remaining three with relevant value 3. There are three lines \( H_j \) that do not pass through the points whose relevant value is 3 and do not intersect in a point. There are 72 such possibilities, \( \binom{4}{3} \cdot 3 \cdot 3 \cdot 2 - \binom{4}{3} \) choices for the fibres with distinguished components, 3 choices for the distinguished component of the first fibre, 3 for the second and 2 for the third. But, applying the trace-residual exact sequence with respect to the three components, we see that \( h^1 \) vanishes.

5) \( W \) defined by all nine singular points: six with relevant value 3, and the remaining three with relevant value 2—the configuration obtained from the preceding one by exchanging 2 with 3. As before, \( h^1 = 0 \) too.

6) \( W \) defined by all nine singular points with relevant value 2. Again \( h^1 \) does not vanish if and only if \( h_A(W) = 6 \). Hence the linear system defining \( W \) becomes

\[
\frac{1}{n} \sum_{j=1}^{12} a^j = 6 \quad \text{and} \quad \frac{1}{n} \sum_{H_j \ni P} a^j = 2 \quad \text{for every singular point} \ P.
\]

Summing up the conditions imposed by the multiple points yields

\[
3 \sum_{j=1}^{12} a^j = 9 \cdot 2n,
\]

hence \( \sum_{H_j \ni P} a^j = 2n \) for every \( P \). But then

\[
6n = \sum_{P \in H_{j_0}} \sum_{H_j \ni P} a^j = 3a^{j_0} + \sum_{H_j \text{ not a component of the fibre that contains } H_{j_0}} a^j.
\]

Hence \( a^j \) is constant along each special fibre of the Hesse pencil and \( |W| = \sigma_4(2n) \).

7) \( W \) defined by all nine singular points with relevant value 3. Arguing as in the previous case, \( h_A(W) = 9 \) and hence we have

\[
\frac{1}{n} \sum_{j=1}^{12} a^j = 9 \quad \text{and} \quad \frac{1}{n} \sum_{j \in \alpha} a^j = 3 \quad \text{for every} \ \alpha,
\]

23
and eventually $|W| = \sigma_4(3n)$. For the computation of the $h^1$ in this case, the trace residual sequence gives

$$0 \to \mathcal{I}_{\sum} P(3) \xrightarrow{\nu} \mathcal{I}_{\sum} 2P(6) \xrightarrow{\tau} \mathcal{O}_E \to 0,$$

where $E$ is a smooth cubic from the Hesse pencil. Now $h^0(\mathbb{P}^2, \mathcal{I}_{\sum} P(3)) = 2$ and $h^0(\mathbb{P}^2, \mathcal{I}_{\sum} 2P_n(6)) \geq 3$, hence $h^0r$ is surjective yielding that $h^1(\mathbb{P}^2, \mathcal{I}_{\sum} 2P_n(6)) = 2$.

Summing up,

$$q(S) = 9 \cdot \sigma_4(2n) + 9 \cdot \sigma_4(3n) + 54 \cdot \sigma_3(2n) + \sigma_4(2n) + 2 \cdot \sigma_4(3n)$$

$$= 10 \frac{(n-1)(5n^2-n-12)}{6} + 11 \frac{(n-1)(n-2)(n-3)}{6} + 54 \frac{(n-1)(n-2)}{2}$$

$$= \frac{(n-1)(61n^2+97n-378)}{6}.$$

\[\square\]

### 4.6 General multiple planes

The last example we would like to consider is one that makes use of Theorem 3.9 in its full generality. Let $A$ be the Ceva’s arrangement with the lines $C_1, \ldots, C_6$ such that $C_i$ and $C_j$ determine a double point if and only if $i + j = 7$. Let $S'$ be the $(\mathbb{Z}/5\mathbb{Z})^3$-abelian covering of $\mathbb{P}^2$ defined by the reduced building data $5L_{\chi_1} \sim 3C_2 + C_3 + C_6$

$$5L_{\chi_2} \sim 2C_1 + 2C_2 + C_4$$

$$5L_{\chi_3} \sim C_1 + 3C_3 + C_5.$$  

It is one of the examples considered by M.-N. Ishida in [9, §6], with $q(S) = 10$, where $S$ is the normalization of $S'$. In [9] it is shown that this surface is a quotient of the Hirzebruch surface constructed as an $(\mathbb{Z}/5\mathbb{Z})^3$-abelian covering of the plane, by the group $(\mathbb{Z}/5\mathbb{Z})^2$. It also verifies $c_1^2 = c_2$. Moreover it is asserted that the surface is isomorphic to the one constructed by M. Inoue (see [8]) from the elliptic modular surface of level 5.

Let us show how the irregularity might be computed using Theorem 3.9. There are non-reduced components in the branch locus and $C_\infty$ is taken to be $C_6$. We have

$$q(S) = \sum_{P \text{ triple point}} |\mathcal{W}(A_P)|_5^M + |\mathcal{W}(A)|_5^M,$$

where

$$M = \begin{bmatrix} 0 & 2 & 1 \\ 3 & 2 & 0 \\ 1 & 0 & 3 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}$$

and $|\mathcal{W}|_5^M = \text{card} \varphi^{-1}(\mathcal{W} \cap [0,1]^6)$, with $\varphi : [0,1]^3 \cap (1/5\mathbb{Z})^3 \to [0,1]^6$ defined by

$$\varphi \left( \frac{a_1}{5}, \frac{a_2}{5}, \frac{a_3}{5} \right) = \left( \left\langle \sum_{j=1}^3 m_j^\ell a_j^j, \frac{a_j}{5} \right\rangle, \ldots, \left\langle \sum_{j=1}^3 m_j^\ell a_j^j, \frac{a_j}{5} \right\rangle \right).$$

24
Here as before, $A_\rho$ is the pencil subarrangement determined by the triple point $P$. An easy computation gives $|W(A_\rho)|^M = 2$ for every triple point. Furthermore, since the equations
\[
\left\langle \frac{2a^2 + a^3}{5} \right\rangle = \left\langle \frac{a^2}{5} \right\rangle, \quad \left\langle \frac{3a^1 + 2a^2}{5} \right\rangle = \left\langle \frac{a^3}{5} \right\rangle, \quad \left\langle \frac{a^1 + 3a^3}{5} \right\rangle = \left\langle \frac{a^2}{5} \right\rangle
\]
and $\langle a^1/5 \rangle + \langle a^2/5 \rangle + \langle a^3/5 \rangle = 2$ lead to the only solutions $(2, 4, 4)$ and $(4, 3, 3)$, it follows that $|W(A)|^M = 2$ also. Hence the irregularity is 10.

**A Technical result**

In the proof of Theorem 3.3 we used two technical results that enabled us to describe the reduced building data of the normalization of a standard covering—which is also a standard covering (see [19, Corollary 3.1])—in terms of the initial reduced building data. The first result was Proposition 3.2 in [17]. The second is somehow similar and deals with the fourth step in the normalization algorithm presented in [19]. It is the step peculiar to the abelian situation.

**Proposition A.1.** Let $X$ be smooth and let $\pi: Y \rightarrow X$ be a standard abelian covering determined by the set of reduced building data $L_{X_i}$ and $B_{f_i}$, $1 \leq j \leq s$ and $f \in S$. Let $C$ be a multiplicity 1 component of both $B_f$ and $B_g$, i.e. $B_f = C + R_f$ and $B_g = C + R_g$. After the normalization procedure has been applied to $C$ and $Y' \rightarrow Y$ is the new surface, if $\chi = x_1^{a_1} \cdots x_s^{a_s}$, then

\[
L'_X \sim \sum_{j=1}^s a_j L_{X_j} - \left[ \sum_{j=1}^s a_j \left( \frac{f(x_j)^*}{m_f} + \frac{g(x_j)^*}{m_g} \right) \right] C \\
- \left[ \sum_{j=1}^s \frac{a_j f(x_j)^*}{m_f} \right] R_f - \left[ \sum_{j=1}^s \frac{a_j g(x_j)^*}{m_g} \right] R_g - \sum_{h \neq f, g} \left[ \sum_{j=1}^s \frac{a_j h(x_j)^*}{m_h} \right] B_h.
\]

**Proof.** Assume that $f: \hat{G} \rightarrow \mathbb{Z}/m_f$ and that $g: \hat{G} \rightarrow \mathbb{Z}/m_g$. Let $d$ and $m$ be the greatest common divisor of, and respectively the smallest common multiple of $m_f$ and $m_g$. If $\varphi: \mathbb{Z}/m_f \times \mathbb{Z}/m_g \rightarrow \mathbb{Z}/m$ is defined by $\varphi(1,0) = m_g/d$ and $\varphi(0,1) = m_f/d$, then set $f': \hat{G} \rightarrow \mathbb{Z}/m_{f'}$ the morphism defined by the composition

\[
\hat{G} \xrightarrow{f \times g} \mathbb{Z}/m_f \times \mathbb{Z}/m_g \xrightarrow{\varphi} \text{Im} \overline{\varphi} \xrightarrow{\iota} \mathbb{Z}/m_{f'}
\]

where $\overline{\varphi}$ is the morphism $\varphi \circ (f \times g)$ and $\iota$ the isomorphism defined by $\iota(m/m_f) = 1$. The normalization of $Y$ along $C$ is constructed by modifying the covering data as follows:

\[
L'_X \sim \begin{cases} 
L_X - C, & \text{if } \frac{f(\chi)^*}{m_f} + \frac{g(\chi)^*}{m_g} \geq 1 \\
L_X, & \text{otherwise}
\end{cases}
\]

25
and

\[ B'_f \sim B_f - C, \quad B'_g \sim B_g - C, \quad B'_{f'} \sim B_{f'} + C, \quad B'_h \sim B_h \quad \text{for} \quad h \neq f, g, f'. \]

Applying these modifications to (6) gives

\[
L'_\chi \sim \sum_j a_j L'_{\chi_j} - \sum_{h \in \delta} \left[ \sum_j \frac{a_j h(\chi_j)^*}{m_h} \right] B_h
\]

\[
\sim \sum_i a_i (L_{\chi_i} - C) + \sum_k \sum_{n} a_k L_{\chi_k} - \left[ \sum_j \frac{a_j f(\chi_j)^*}{m_f} \right] R_f - \left[ \sum_j \frac{a_j g(\chi_j)^*}{m_g} \right] R_g
\]

\[
- \left[ \sum_j \frac{a_j f'(\chi_j)^*}{m_{f'}} \right] (B_{f'} + C) - \sum_{h \neq f, g, f'} \left[ \sum_j \frac{a_j h(\chi_j)^*}{m_h} \right] B_h,
\]

where the sum \( \sum' \) runs over those \( i \)'s for which \( f(\chi)^*/m_f + g(\chi)^*/m_g \geq 1 \) and \( \sum'' \) over the other \( k \)'s. To prove the result it is sufficient to show that

\[
\sum'_i a_i + \left[ \sum_j \frac{a_j f'(\chi_j)^*}{m_{f'}} \right] = \left[ \sum_{j=1}^{s} a_j \left( \frac{f(\chi_j)^*}{m_f} + \frac{g(\chi_j)^*}{m_g} \right) \right].
\]

But

\[
\left[ \sum_j \frac{a_j f'(\chi_j)^*}{m_{f'}} \right] = \left[ \sum_j \frac{a_j}{m_{f'}} \left( \frac{m_g f(\chi_j)^*}{m_f} + \frac{m_f g(\chi_j)^*}{m_g} \right) m_{ff'} \right]
\]

\[
= \left[ \sum'_i + \sum''_k \right].
\]

Since for each \( i \) in the first sum

\[
\left( \frac{m_g f(\chi_i)^*}{m_f} + \frac{m_f g(\chi_i)^*}{m_g} \right)^* = \frac{m_g}{m} f(\chi_i)^* + \frac{m_f}{m} g(\chi_i)^* - m
\]

and for each \( k \) in the second

\[
\left( \frac{m_g f(\chi_k)^*}{m_f} + \frac{m_f g(\chi_k)^*}{m_g} \right)^* = \frac{m_g}{m} f(\chi_k)^* + \frac{m_f}{m} g(\chi_k)^*,
\]

the identity follows. \( \square \)
