We discuss the relation between the $T^2$-coefficient of electrical resistivity $A$ and the $T$-linear specific-heat coefficient $\gamma$ for heavy-fermion systems with general $N$, where $N$ is the degeneracy of quasi-particles. A set of experimental data reveals that the Kadowaki-Woods relation: $A/\gamma^2 = 1 \times 10^{-5} \mu\Omega/(K\,mol/m^3)^2$, collapses remarkably for large-$N$ systems, although this relation has been regarded to be commonly applicable to the Fermi-liquids. Instead, based on the Fermi-liquid theory we propose a new relation: $\tilde{A}/\gamma^2 = 1 \times 10^{-5}$ with $\tilde{A} = 2A/N(N-1)$ and $\tilde{\gamma} = \gamma/2N(N-1)$. This new relation exhibits an excellent agreement with the data for whole the range of degenerate heavy-fermions.

PACS numbers: 71.10.Ay, 71.27.+a, 75.30.Mb

The Fermi-liquid theory has suggested that the values of $A/\gamma^2$, so far considered to be unique and independent on materials, do depend on the number of degeneracy of quasi-particles $N$. For isolated atoms, $N$ is defined as $N = 2J + 1$ with $J$ the total angular momentum. In solids, $N$ can vary due to the competition between the crystal-field splitting $\Delta$ and the Kondo temperature $T_K$. For $T_K < \Delta$, the low-temperature properties are basically explained by $N = 2 (S = 1/2)$ Kondo model, since most of the degeneracy are lost due to the large $\Delta$. For $T_K > \Delta$, on the contrary, the crystal field splittings are covered by the large Kondo effect, and the degeneracy are almost preserved down to low temperatures. In this case, the theory gives the failed universality of $A/\gamma^2$.

In this paper, we make a quantitative comparison of the experimental data in ref. and several recent works with the theoretical results of ref. The results display a beautiful agreement between experiments and theory. Furthermore, we propose an advanced relation for $A$ and $\gamma$ based on these results. Using $\tilde{A}$ and $\tilde{\gamma}$, the values of $A$ and $\gamma$ normalized by $4N(N-1)$, we show that these two values of heavy-fermion systems with general $N$ are related by a very simple formula: $\tilde{A}/\tilde{\gamma}^2 = 1 \times 10^{-5} \mu\Omega/cm(K\,mol/m^3)^2$. This new relation, namely, the ‘grand-KW-relation’, will be an important waymark for the research of strongly-correlated electron systems with degeneracies, and remarkably extends the validity of the Fermi-liquid theory.

At first, we briefly describe the theoretical results of ref. For the case of strong-coupling limit where $m^*/m \gg 1$ ($m^*$ and $m$ being the mass of heavy quasi-particles and free electrons, respectively), the orbitally-degenerate periodic Anderson (ODPA) model gives:

\begin{equation}
A = \frac{\hbar k_B^2}{e^2} \frac{3\pi^6}{2k_F^4} N(N-1) \Gamma_{\text{loc}}^2(0,0) \rho^4_l(0),
\end{equation}

\begin{equation}
\gamma = N_A k_B^2 \frac{\pi^2}{6} N(N-1) \Gamma_{\text{loc}}(0,0) \rho^2_l(0).
\end{equation}
where $h$ is the Plank constant, $k_B$ the Boltzmann constant, $k_F$ the Fermi momentum, and $N_A$ the Avogadro number. In addition, $a$ is the unit-cell length, and $\rho_f(0)$ the density of states per $f$-orbit at the Fermi energy. $\Gamma_{\text{loc}}(0,0)$ represents the effective interaction between quasi-particles. Note that $A$ and $\gamma$ given in eq.(1) and (2) are not simply proportional to $N(N-1)$, because $\Gamma_{\text{loc}}(0,0)$ also depends on $N$. The value $A/\gamma^2$ is then deduced as [14].

$$\frac{A}{\gamma^2} = \frac{h}{e^2 k_B N_A^2} \cdot \frac{9(3\pi^2)^{-1/3}}{n^{2/3} a^3} \cdot \frac{1}{\frac{1}{2} N(N-1)} = 1 \times 10^{-5} \mu\Omega cm(Kmol/mJ)^2. \quad (3)$$

For the case of $N = 2$, this formula gives the KW-relation. For general $N$, this gives a set of universal relations. This is shown in Figure 1 as the solid lines for $N = 2, 4, 6, \text{and } 8$.

In the figure, experimental data are also plotted after ref. [16]. At first, one can see that many heavy-fermion systems such as CeCu$_6$, or CeCu$_2$Si$_2$ agree with the KW-relation; i.e., the theoretical prediction for $N = 2$. This is consistent with the situation $T_K < \Delta$, which results in the low degeneracy of $N = 2$ [13]. Moreover, it is clear that many Yb- and Ce-based systems, which have deviated from the KW-relation, well agree with the theoretical predictions for $N = 6-8$.

It should also be noted that the $A/\gamma^2$ of Eu- and Sm-based compounds agrees very well with the line for $N = 8$ and $N = 4$, respectively. These Eu-compounds are considered to be intermediate-valent between $\text{Eu}^{2+}(S = 7/2)$ and $\text{Eu}^{3+}(J = 0)$ [13]. The Fermi-liquid state of them is hence considered to be emerged out of the degeneracy $N = 2S + 1 = 8$. For the two Sm-based systems, the value of $N = 4$ has been assumed, since the lowest CEF levels are considered to be a quartet [17] [18]. These quantitative agreements of $A/\gamma^2$ with respective theoretical lines evidences that $A/\gamma^2$ of heavy-fermion systems are not specific to materials, but are commonly scaled by degeneracy.

In the following, we go forward to unify these relations into a single relation. If the value of $N$ is determined experimentally, we can define the normalized coefficients $\tilde{A}$ and $\tilde{\gamma}$ from the eq.(1) and (2) as:

$$\tilde{A} = \frac{A}{\frac{1}{2} N(N-1)}, \quad \tilde{\gamma} = \frac{\gamma}{\frac{1}{2} N(N-1)}.$$  

Then $\tilde{A}/\tilde{\gamma}^2$ is obtained from the eq.(3) as:

$$\tilde{A}/\tilde{\gamma}^2 \approx 1 \times 10^{-5} \mu\Omega cm(Kmol/mJ)^2. \quad (4)$$

This formula does not include any $N$-dependence. Hence, this should be applicable to arbitrary-$N$ systems.

In Figure 2, we plot $\tilde{A}$ and $\tilde{\gamma}$ of $f$-electron based systems. For uranium compounds, we have tentatively assumed $N = 2$, which is discussed later. One can see that

$$A/\gamma^2 = 1 \times 10^{-4} \mu\Omega cm(Kmol/mJ)^2$$

for $N = 2$.

\[ \text{FIG. 1: } T^2\text{-coefficient of electrical resistivity } A, \text{ vs. } T\text{-linear coefficient of specific heat } \gamma \text{ of heavy-fermion systems with various degeneracy. Experimental data are taken from ref. [5, 8, 11, 14, 18]. The black line corresponds to the Kadowaki-Woods relation [8]. Other solid lines are the prediction from the orbitally-degenerate periodic-Anderson model [10]. Colors of the symbols represent the degeneracy of the Fermi-liquid theory. We would like to stress that this rule holds when system is reached toward the quantum critical point (QCP). Even in the vicinity of the QCP, the Fermi-liquid state is realized at sufficiently low temperatures below a characteristic temperature } (T_{\text{coh}}, \text{ in literatures}) \text{ as far as the system is in the magnetically disordered side. In this case, our theory yields that } \text{the eq.}(4) \text{ scales } \tilde{A} \text{ and } \tilde{\gamma} \text{ universally for a wide range of materials. This fact shows the validity of the theoretical approach using the ODPA model, and extends the validity of the Fermi-liquid theory. We would like to stress that our new relation has the same form just as the original KW-relation. The formula } (4) \text{ may hence be called as } \text{‘grand-KW-relation for general degeneracy’}. \]

\[ \text{Here it would be interesting to discuss to what extent this rule holds when system is reached toward the quantum critical point (QCP). Even in the vicinity of the QCP, the Fermi-liquid state is realized at sufficiently low temperatures below a characteristic temperature } (T_{\text{coh}}, \text{ in literatures}) \text{ as far as the system is in the magnetically disordered side. In this case, our theory yields that } \text{the eq.}(4) \text{ scales } \tilde{A} \text{ and } \tilde{\gamma} \text{ universally for a wide range of materials. This fact shows the validity of the theoretical approach using the ODPA model, and extends the validity of the Fermi-liquid theory. We would like to stress that our new relation has the same form just as the original KW-relation. The formula } (4) \text{ may hence be called as } \text{‘grand-KW-relation for general degeneracy’}. \]
the value of $\tilde{A}/\gamma^2$ defined at the low temperature limit ($T \to 0$), follows the relation (4) even in the vicinity of QCP. This is because our theory is derived for the limit of $T \to 0$, though CePd$_3$ shows a large deviation from eq.(4), though CePd$_3$ well agrees with the original KW-relation [7]. This discrepancy results from the large degeneracy, $N = 6$ for CePd$_3$. It should be noted that CePd$_3$ has very small carrier-concentration (0.3 electrons per f.u.) [20]. The $A/\gamma^2$ value is found to depend on $n$ as proportional to $n^{-4/3}$ from eq.(3) and also from other theoretical studies [2, 20, 21, 27]. Taking this into consideration, the deviation of CePd$_3$ from the universal line is reasonable. Similar deviation is reported for the Kondo semiconductor CeNiSn [28]. Anomalously large $A$ value ($54 \mu\Omega cm/K^2$) compared to its $\gamma$ ($40 \text{ mJ/mol K}^2$) has been attributed to its extremely low carrier concentration [28].

The compounds CeNi($N = 6$) and YbCuAl($N = 8$) also show slight deviations, possibly due to the error in the $N$ estimations. For other exceptions, YbInAu$_2$ and Yb$_2$Co$_3$Ga$_9$, we have no explanation for the origin of deviation. Other causes such as multi-Fermi-surface effect [8] may have to be considered. In addition, strong anisotropy of the Fermi surface can cause deviation from the universal relation [2, 20]. This effect would be in general more prominent in d-electron systems [50, 51].

For U-based compounds, its degeneracy has been the subject of arguments. If the 5f-electrons are well localized, $N$ can be determined experimentally, as in the case of UPd$_3$ [32]. In most of U-compounds, however, it is considered that the 5f-electrons have more itinerant character than 4f, since 5f-orbitals are spatially more expanded. The definition of $N$ in U-compounds is therefore ambiguous. Here, one can see in Fig.1 and Fig.2 that those U-compounds well agree with the theoretical prediction for $N = 2$. This can lead us to the possibility that the orbital degree of freedom is quenched and only the spin degree of freedom participates in the Fermi-liquid state in these 5f-systems, similar to transition metals. Although the estimation of $N$ from the $A/\gamma^2$ plot is not conclusive, this plot may serve as a hint to discuss the puzzling 5f-electrons.

In addition, we note that the grand-KW-relation is also powerful to describe the pressure dependent properties of heavy-fermion systems. In CeCu$_2$Ge$_2$ (or YbNi$_2$Ge$_2$), it is suggested that the value of $A/\gamma^2$ reduces (or increases) about 25 times at high pressures [33, 34] probably due to the change of $N$ by pressures. In our plot of $\tilde{A}$ and $\tilde{\gamma}$, these crossover would be described on the single scaling without breaking the universality. This situation may be hence ideal for the continuity principle of the Landau

![Graph showing the plot of $\tilde{A}$ and $\tilde{\gamma}$ of heavy-fermion systems. $\tilde{A}$ and $\tilde{\gamma}$ are the divided values of $A$ and $\gamma$ by $\frac{1}{2}N(N-1)$, respectively. $N$ of the U-based compounds is tentatively assumed to be 2. The dotted line represents the grand KW-relation (4) given in the text; $\tilde{A}/\tilde{\gamma}^2 = 1 \times 10^{-5} \mu\Omega(K/mol/J)^2$.](image)
Fermi-liquid theory \[13\]. Current interests in strongly-correlated electron systems are extended to the orbitally-degenerate cases. Hence, the grand-KW-relation will be one of the most fundamental relations in Fermi-liquid systems. We also comment that the effect of the degeneracy is one of the most fundamental relations in Fermi-liquid systems. Hence, the grand-KW-relation will be relevant in such systems. Therefore, the degeneracy relevant to the Fermi-liquid behavior should be much smaller than 4.

[13] The eq.(1) and (2) explicitly describes the units like $k_B$ and $h$, that were omitted in the equations of ref. 15.
[14] Here the free electron model $k_F = (3\pi^2 n)^{1/3}$ ($n$ being the carrier concentration) is employed. For numerical estimation, we have assumed $n^{5/3}a^3 \approx 1 \times 10^5 \text{cm}^{-1}$. This assumption corresponds to 3.3 carriers per formula unit for $a = 5\text{Å}$ or to 2.8 carriers per f.u. for $a = 4\text{Å}$, which seems to be typical values for them. Formula unit is to include only one rare-earth ion.
[15] For the values of $N$, we have employed the data listed in ref. 8, most of which were determined by fitting the specific heat using the impurity-Kondo models. Although the real system is periodic, we believe that this estimation of $N$ is reliable, because these fittings are performed for the data at relatively high temperatures, at which intersite effect are not prominent. However, it is difficult to determine the value of $N$ explicitly when $\Delta$ (crystal-field splitting) and $\tau_K$ are comparable.

[19] The lowest crystal-field level in CeB$_6$ is considered to be a quartet. However, we note that the Fermi-liquid behavior in this system is only observed below 0.5 K, which is much lower than the quadrupolar-ordering temperature of 3.3 K [N. Sato, A. Sumiyama, S. Kunii, H. Nagano, and T. Kasuya, J. Phys. Soc. Jpn. 54, 1923 (1985)]. Therefore, the degeneracy relevant to the Fermi-liquid behavior should be much smaller than 4.

[27] In the reference 21, $A/\gamma^2 \propto \rho_0 \propto (N^2\tau_{K_0})^{-1} \propto k_F^2/n^2$. Assuming $k_F = (3\pi^2 n)^{1/3}$, this gives the $n^{-4/3}$ dependence.

[31] $A/\gamma^2$ of transition metals like Pd and Pt also deviates from the KW-relation, and is the same order as that of the degenerate heavy-fermion systems ($N \approx 8$); $A/\gamma^2 = 0.4 \times 10^{-6} \mu\Omega\text{cm}(K \text{ mol/ml})^2$ [M. J. Rice, Phys. Rev. Lett. 20, 1439 (1968)]. However, these transition metals are not likely to hold the universal relation, eq.(4), because $N$ of these metals would be close to 2 due to the quenching of the orbital moment. $A/\gamma^2$ of these metals is hence much smaller than eq.(4). Here, note that the theory 10 we use in the present work is based on the strong-coupling case ($n^2/n \gg 1$), which is apparently not the case of these metals. For such weak-coupling cases, deviation from the KW-relation is suggested theoretically in [K. Miyake, T. Matsuura and C. M. Varma, Solid State Commun. 71, 1149 (1989)].
