Abstract

Three-body resonances in the $\bar{K}NN$ system have been studied within a framework of the $\bar{K}NN - \piYN$ coupled-channel Faddeev equation. By solving the three-body equation, the energy dependence of the resonant $\bar{K}N$ amplitude is fully taken into account. The S-matrix pole has been investigated from the eigenvalue of the kernel with the analytic continuation of the scattering amplitude on the unphysical Riemann sheet. The $\bar{K}N$ interaction is constructed from the leading order term of the chiral Lagrangian using relativistic kinematics. The $\Lambda(1405)$ resonance is dynamically generated in this model, where the $\bar{K}N$ interaction parameters are fitted to the data of scattering length. As a result we find a three-body resonance of the strange dibaryon system with binding energy, $B \sim 79$ MeV, and width, $\Gamma \sim 74$ MeV. The energy of the three-body resonance is found to be sensitive to the model of the $I = 0$ $\bar{K}N$ interaction.

I. INTRODUCTION

The analysis of the kaonic atoms [1] revealed an attractive $\bar{K}$-nucleus interaction. Although the strength of the attraction depends on the parametrization of the density dependence of the optical potential [1] and the theoretical study of the $\bar{K}$ optical potential suggests a rather shallow potential [2], there has been a great interest in the possibilities of $\bar{K}$-nucleus bound states in recent years. Akaishi and Yamazaki [3, 4] studied the kaon bound states in light nuclei and found deeply bound kaonic states, for example, $B \sim 100$ MeV for $^3\bar{K}H$. In their study, the kaonic nuclear states were investigated by using the $\bar{K}$ optical potential, which is constructed by folding the $g$ matrix with a trial nuclear density. The potential model of $\bar{K}N - \pi\Sigma$ interaction is determined to reproduce the $\Lambda(1405)$ and the scattering length. The kaonic nuclear states are further studied by using a method of antisymmetrised molecular dynamics [5] using the $\bar{K}N g$ matrix.

Among the simplest $\bar{K}$ nucleus state, the $K^-pp$ state, which has strangeness $S = -1$, total angular momentum and parity $J^p = 0^-$, and isospin $I = 1/2$ dibaryon state, is expected to have largest component of the $I = 0 \bar{K}N$. An experimental signal of the $K^-pp$ bound state is reported by the FINUDA Collaboration from the analysis of the invariant mass distribution of $\Lambda - p$ in the $K^-$ absorption reaction on nuclei [6]. The reported central value of the binding energy, $B$, and the width, $\Gamma$, are $(B, \Gamma) = (115, 67)$ MeV, which is below the $\pi\Sigma N$ threshold energy. This data may be compared with the predicted values $(B, \Gamma) = (48, 61)$ MeV in Ref. [4]. However it was pointed out that the data can be understood by the two-nucleon absorption of $K^-$ in nuclei together with the final state interaction of the outgoing baryons [7].

In the attractive interaction of kaon in nuclei, the resonance $\Lambda(1405)$ in the s-wave and $I = 0$ channel $\bar{K}N$ scattering state plays an essential role. The energy of the $\Lambda(1405)$ is below the $\bar{K}N$ threshold and strongly couples with the $\pi\Sigma$ state. Although the kaonic nuclear states have been studied so far by using the $\bar{K}N g$ matrix or optical potential, it might be very important to examine the full dynamical calculation of $\bar{K}N - \pi\Sigma$ system by taking into account the energy dependence of the resonance $t$ matrix and the coupling with the $\bar{K}N - \pi\Sigma$ channel explicitly. Such a theoretical study may be possible in the simplest kaonic nuclei with baryon number $B = 2$ system. In this work, we study the strange dibaryon system by taking into account the three-body dynamics using the $\bar{K}NN - \pi\Sigma N - \pi\Lambda N (\bar{K}NN - \piYN)$
coupled-channel Faddeev equation with relativistic and non-relativistic kinematics.

Methods to investigate resonances in the three-body system have been developed in the studies of the three-neutron \[8, 9\], \(\pi N N\) dibaryon \[10, 11\], and \(\Sigma N N\) hypernuclei \[10, 12, 13\]. In this work, we employ a method started by Glöckle \[8\] and Möller \[9\] and developed by Matsuyama and Yazaki, Afnan, Pearce and Gibson \[10, 12, 13\] to find a pole of the S matrix in the unphysical energy plane from the eigenvalue of the kernel of the Faddeev equation. To analytically continue the scattering amplitude into the unphysical sheet, the path of the momentum integral must be carefully deformed in the complex plane to avoid possible singularities.

The most important interaction for the study of the strange dibaryon system is for the \(I = 0\) \(\bar{K}N\) states. The internal structure of the \(\Lambda(1405)\) has been a long standing issue. The chiral Lagrangian \[14, 15, 16\] approach can describe well the low energy \(\bar{K}N\) reaction with the meson-baryon dynamics. A genuine \(q^3\) picture of the \(\Lambda(1405)\) coupled with meson-baryon \[17\] may not yet be excluded. Though previous studies of the \(\bar{K}NN\) system used phenomenological models of the \(\bar{K}N\) potentials, we use s-wave meson-baryon coupled-channel potentials guided by the lowest order chiral Lagrangian. With this model, the strength of the potentials and the relative strength of the potentials among various meson-baryon channels are not parameters but are determined from the SU(3) structure of the chiral Lagrangian. In this model, the \(\Lambda(1405)\) is an ‘unstable bound state’, whose pole on the unphysical sheet will become the bound state of \(\bar{K}N\) when the coupling between the \(\bar{K}N\) and the \(\pi Y\) is turned off. We examine a relativistic model as well as a nonrelativistic model to account for the relativistic energy of pion in the \(\pi YN\) state.

We briefly explain our \(\bar{K}NN - \pi YN\) coupled-channel equations and the procedure to search for the three-body resonance in section 2. The model of the two-body interactions used in this work is explained in section 3. We then report our results on the \(\bar{K}NN\) dibaryon resonance in section 4. This work is the extension of the early version of our analysis reported in Ref. \[18\]. Recently Shevchenko \textit{et al.} \[19\] performed a similar study of the \(\bar{K}NN\) system using Faddeev equation starting from the phenomenological \(\bar{K}N\) interaction within a nonrelativistic framework. The comparison of our results with theirs will be discussed in section 4.
II. COUPLED CHANNEL FADDEEV EQUATION AND RESONANCE POLE

We start from the Alt-Grassberger-Sandhas (AGS) equation \([20]\) for the three-body scattering problem. The operators \(U_{i,j}\) of the three-body scattering satisfy the AGS equation

\[
U_{i,j} = (1 - \delta_{i,j})G_0^{-1} + \sum_{n \neq i} t_n G_0 U_{n,j}. \tag{1}
\]

Here we label the pair of particles \(j, k\) by the spectator particle \(i = 1, 2, 3\). The two-body \(t\) matrix \(t_i\) of particles \(j, k\) with the spectator particle \(i\) is given by the solution of the Lippmann-Schwinger equation:

\[
t_i = v_i + v_i G_0 t_i. \tag{2}
\]

Here \(G_0 = 1/(W - H_0 + i\epsilon)\) is the free Green’s function of the three particles, and \(W\) is the total energy of the three-body system.

When the two-body interactions \(v_i\) are given in separable form with the vertex form factor \(|g_i>\) and the coupling constant \(\gamma_i\) as

\[
v_i = |g_i > \gamma_i < g_i|, \tag{3}
\]

the AGS-equation of Eq. (1) is written in the form

\[
X_{i,j}(\vec{p_i}, \vec{p_j}, W) = (1 - \delta_{i,j})Z_{i,j}(\vec{p_i}, \vec{p_j}, W) + \sum_{n \neq i} \int d\vec{p}_n Z_{i,n}(\vec{p_i}, \vec{p_n}, W)\tau_n(W)X_{n,j}(\vec{p_n}, \vec{p_j}, W). \tag{4}
\]

The amplitude \(X_{i,j}\) is defined by the matrix element of \(U_{i,j}\) between state vectors \(G_0|\vec{p}_i, g_i>\) as

\[
X_{i,j}(\vec{p}_i, \vec{p}_j, W) = <\vec{p}_i, g_i|G_0 U_{i,j} G_0|\vec{p}_j, g_j>. \tag{5}
\]

The state vector \(|\vec{p}_i, g_i>\) represents a plane wave state of the spectator \(i\) and the state vector \(|g_i>\) of the interacting pair.

The driving term \(Z_{i,j}\) of Eq. (4) shown in Fig. (a) is given by the particle exchange mechanism defined as

\[
Z_{i,j}(\vec{p}_i, \vec{p}_j, W) = <\vec{p}_i, g_i|G_0|\vec{p}_j, g_j> \frac{g^*(\vec{q}_i) g(\vec{q}_j)}{W - E_i(\vec{p}_i) - E_j(\vec{p}_j) - E_k(\vec{p}_k)}. \tag{6}
\]
Here the momentum of the exchanged particle \( k(\neq i, j) \) is given as \( \vec{p}_k = -\vec{p}_i - \vec{p}_j \) and \( g(q_i) \) is the vertex form factor of the two-body interaction \( g(q_i) = \langle g_i | q_i | g_i \rangle \). The energy \( E_i(\vec{p}_i) \) is given by \( E_i(\vec{p}_i) = m_i + \vec{p}_i^2/2m_i \) for the non-relativistic model and \( E_i(\vec{p}_i) = \sqrt{m_i^2 + \vec{p}_i^2} \) for the relativistic model. The relative momentum is given by \( q_i = (m_k\vec{p}_j - m_j\vec{p}_k)/(m_j + m_k) \) for the non-relativistic model, while we define \( q_i = |\vec{q}_i| \) for the relativistic model as

\[
q_i = \sqrt{\left(\frac{(W_i^2 + m_j^2 - m_k^2)}{2W_i}\right)^2 - m_j^2}, \tag{8}
\]
\[
W_i = \sqrt{(E_j(\vec{p}_j) + E_k(\vec{p}_k))^2 - \vec{p}_i^2}. \tag{9}
\]

The two-body t matrix can be solved for the separable interaction as

\[
t_i = |g_i > \tau_i(W) < g_i|. \tag{10}
\]

Here the 'isobar' propagator \( \tau_i \), illustrated in Fig. (b), is given as

\[
\tau_i(W) = \left[ 1/\gamma_i - \int dq_i \frac{|g_i(q_i)|^2}{W - E_i(\vec{p}_i) - E_{jk}(\vec{p}_i, q_i)} \right]^{-1}. \tag{11}
\]

The two-body t matrix depends on the energy \( E_i(\vec{p}_i) \) of the spectator particle. Here \( E_{jk} \) is the energy of the interacting pair given as \( E_{jk}(\vec{p}_i, q_i) = m_j + m_k + \vec{p}_i^2/(m_j + m_k) + q_i^2/\mu_i \) for the non-relativistic model, while \( E_{jk}(\vec{p}_i, q_i) = \sqrt{(E_j(q_i) + E_k(q_i))^2 + \vec{p}_i^2} \) for the relativistic model. The reduced mass is defined as \( \mu_i = m_jm_k/(m_j + m_k) \).
Following the standard method of angular momentum expansion [21], the AGS equation reduces to following coupled integral equations by keeping only s-wave states:

\[ X_{i,j}(p_i, p_j, W) = Z_{i,j}(p_i, p_j, W) + \sum_n \int dp_n p_n^2 K_{i,n}(p_i, p_n, W) X_{n,j}(p_n, p_j, W). \] (12)

Here we used a simplified notation for the kernel \( K = Z \tau \), which can be written as

\[ K_{i,n}(p_i, p_n, W) = 2\pi \int d(\hat{p}_i \cdot \hat{p}_n) \frac{g_s(q_i)g_s(q_n)}{W - E_i(p_i) - E_j(p_n) - E_k(\hat{p}_i + \hat{p}_n)} \tau_n(W). \] (13)

The formulas given above are valid for the spinless and distinguishable particles without channel coupling among the Fock-space vectors. In our \( KNN \) resonance problem, we have included the following \( \bar{K}NN \) and \( \pi YN \) states:

\[ |a> = |N_1, N_2, \bar{K}_3>, \] (14)
\[ |b> = |N_1, Y_2, \pi_3>, \] (15)
\[ |c> = |Y_1, N_2, \pi_3>, \] (16)

with \( Y_i \) is \( \Sigma_i \) or \( \Lambda_i \). After anti-symmetrizing the amplitude for identical particles of nucleons [11], we obtain the following forms of the coupled AGS equations,

\[
\begin{pmatrix}
X_{Y_K,Y_K} \\
X_{Y_K,N^*} \\
X_{d,Y_K} \\
X_{N^*,Y_K}
\end{pmatrix}
= \begin{pmatrix}
Z_{Y_K,Y_K} \\
0 \\
Z_{d,Y_K} \\
0
\end{pmatrix}
\begin{pmatrix}
X_{Y_K,Y_K} \\
X_{Y_K,N^*} \\
X_{d,Y_K} \\
X_{N^*,Y_K}
\end{pmatrix}
+ \begin{pmatrix}
-Z_{Y_K,Y_K} \tau_{Y_K,Y_K} -Z_{Y_K,Y_K} \tau_{Y_K,Y_\pi} 2Z_{Y_K,d} \tau_{d,d} & 0 \\
0 & 0 & 0 & -Z_{Y_\pi,N^*} \tau_{N^*,N^*} \\
Z_{d,Y_K} \tau_{Y_K,Y_K} & Z_{d,Y_K} \tau_{Y_K,Y_\pi} & 0 & 0 \\
-Z_{N^*,Y_\pi} \tau_{Y_\pi,Y_K} & -Z_{N^*,Y_\pi} \tau_{Y_\pi,Y_\pi} & 0 & 0
\end{pmatrix}
\begin{pmatrix}
X_{Y_K,Y_K} \\
X_{Y_K,N^*} \\
X_{d,Y_K} \\
X_{N^*,Y_K}
\end{pmatrix}. \] (17)

Here we have suppressed the spin-isospin quantum numbers, the spectator momentum \( p_j \) and the total energy of the three-body system \( W \) in \( Z, X \) and \( \tau \) for simplicity. The concise notation of \( Y_K, Y_\pi, d \) and \( N^* \) represents the ‘isobars’ and their decay channels. The decay channels of isobars \( Y_K, Y_\pi, d \) and \( N^* \) are \( \bar{K}N(I = 0, 1), \pi \Sigma(I = 0, 1) \) and \( \pi \Lambda(I = 1), NN(I = 1) \) and \( \pi N(I = 1/2, 3/2) \), respectively. Here \( I \) is isobar isospin. Those indices
uniquely specify the three-body states of $X$ and $Z$ except $N^*$ showing $\Sigma N^*$ and $\Lambda N^*$. Therefore we have a nine-channel coupled equation of Eq. (17) for spin singlet, s-wave three-body system. The explicit form of Eq. (7) when we include spin-isospin is summarized in the Appendix.

The dominant Fock space component is expected to be $|\bar{K}NN>$, and therefore the most important amplitudes are $X_{Y_K,Y_K}$ and $X_{d,Y_K}$. They couple to each other through the kaon exchange $Z_{Y_K,Y_K}$ and nucleon exchange $Z_{Y_K,d}$ mechanisms. Notice, however, the $\pi YN$ component is also implicitly included in $\tau_{Y_K,Y_K}$ when we solve the two-body $\bar{K}N - \pi Y$ coupled-channel equations. The $\pi YN$ components, $X_{Y\pi,Y_K}$ and $X_{N^*,Y_K}$, couple with the $\bar{K}NN$ components through the pion exchange mechanism $Z_{N^*,Y_n}$ and the $\pi N$ and $\pi Y$ 'isobars' $\tau_{N^*,N^*}, \tau_{Y\pi,Y}$. The pion exchange mechanism may play an important role in the width of the resonance. In this work, we have not included weak $YN$ interaction. It was found in Ref. [19] that the $YN$ interaction plays rather minor role in this strange dibaryon system.

To find the resonance energy of the three-body system using the AGS equation of Eq. (17), we follow the method used in Refs. [8, 9, 10, 12, 13]. The AGS equation of Eq. (13) is a Fredholm-type integral equation with the kernel $K = Z\tau$. Using the eigenvalue $\eta_a(W)$ and the eigenfunction $|\phi_a(W)>$ of the kernel for given energy $W$,

$$Z\tau|\phi_a(W)> = \eta_a(W)|\phi_a(W)>,$$

(18)

the scattering amplitude $X$ can be written as

$$X = \sum_{a} \frac{|\phi_a(W)> <\phi_a(W)|Z}{1 - \eta_a(W)}.$$  

(19)

At the energy $W = W_p$ where $\eta_a(W_p) = 1$, the amplitude has a pole, and therefore $W_p$ gives the bound state or resonance energy.

Since a resonance pole appears on the unphysical energy Riemann sheet, we need analytic continuation of the scattering amplitude. We use here the nonrelativistic model to explain a method of analytic continuation, which is based on Refs. [9, 10]. At first we examine the singularities of the kernel of Eq. (13). Above the threshold energy of the three-body break up $W > m_i + m_j + m_k$, $Z(p_i, p_n, W)$ has logarithmic singularities. The branch points appear
FIG. 2: The singularities of the one particle exchange interaction $Z(p_i, p_n, W)$ in the complex $p_n$ plane at $W = E + i\epsilon$ and the real $p_i$.

at $p_n = \pm p_{Z1,2}$, where

$$p_{Z1} = -\frac{\mu_j}{m_k} p_i + \sqrt{2\mu_j W_{th} - \frac{\mu_j^2}{\eta_j} p_i^2};$$

$$p_{Z2} = +\frac{\mu_j}{m_k} p_i + \sqrt{2\mu_j W_{th} - \frac{\mu_j^2}{\eta_j} p_i^2};$$

with

$$\mu_j = \frac{m_i m_k}{m_i + m_k},$$

$$\eta_j = \frac{m_j (m_i + m_k)}{m_i + m_j + m_k},$$

$$W_{th} = W - m_i - m_j - m_k.$$
FIG. 3: The integration contour $C$ and the singularity of $Z$ at $W = E - i\Gamma/2$ and real value of $p_i$.

In principle it might be possible to solve the AGS equation keeping the momentum variables real and taking into account the discontinuity across the cut. The moving logarithmic singularities depending on $p_i$ make it difficult to solve the integral equation. To overcome this problem we deform the integration contour of $p_i$, $p_n$, into the fourth quadrant of the complex momentum plane so that we take into account the contribution of the cuts. As an example of our $\bar{K}NN - \pi YN$ problem, we choose the integration contour of $p_n$ as shown in solid line in Fig. 4. Here we take the energy $W = 10 - i 35 + m_x + m_{\Sigma} + m_N$ MeV, which is below the mass of $\bar{K}NN$ and above the $\pi YN$. The shaded region in Fig. 4 shows the cuts of 'Z' for the pion exchange mechanism. The cuts become 'forbidden regions' because the position of the cuts depends on $p_i$, which runs the same integration contour as $p_n$. In our numerical calculation, we studied all the 'forbidden regions' for $\pi, N$ and $K$ exchange mechanism and determined the integration contour. With the integration contour $C$ in Fig. 4 we choose the physical sheet of $\bar{K}NN$.

The singularities of the isobar propagator $\tau(W)$ arises from the three-body Green’s function in the integrand of $\tau$. The poles are at $q_n = \pm \sqrt{2\mu_j W_{th} - \frac{\mu_j}{\eta_j} p_i^2}$. Since $q_s = (p_{Z_1} + p_{Z_2})/2$, we can analytically continue it into the same unphysical sheet as the case in $Z$ as long as we keep the same deformed contour as the one used in $Z$. Another singularity we have to worry about is the singularity due to the two-body resonance. Since our $\bar{K}N - \pi \Sigma$ system has the two-body resonance $\Lambda(1405)$, the cut starts from the two-body resonance energy in the complex energy plane. To examine this, we write the approximate energy dependence...
FIG. 4: The logarithmic singularities of the $\pi$ exchange mechanism $Z(p_i, p_n, Z)$ at $W_{th} = 10 - 35$ MeV in the complex $p_n$ plane. $C$ is integration contour of $p_n$ and $p_i$.

of the $\tau$ as

$$\tau_i(W) \sim \frac{1}{W - \frac{p_N^2}{2\eta_N} - E_{\Lambda^*} - m_N}. \quad (22)$$

Here $p_N$ and $m_N$ are the momentum and mass of the spectator nucleon. The reduced mass of the spectator nucleon with the isobar pair $KN$ or $\pi\Sigma$ is denoted as $\eta_N$ and $E_{\Lambda^*}$ is the pole energy of $\Lambda(1405)$. At $W = \frac{p_N^2}{2\eta_N} + E_{\Lambda^*} + m_N$ with $p_N$ on the contour $C$ in Figs. 5 (b), the two-body t-matrix has a singularity, which is plotted as a solid line in Fig. 5(a). We illustrate the typical trajectories of the three-body resonance pole $W = W_p$ as curves A and B in Fig. 5. If the pole trajectories A and B intercept the two-body $N\Lambda(1405)$ cut, then the analytic continuation to the $N\Lambda(1405)$ unphysical energy sheet must be examined. The same situation from the $p_N$ plane is shown in Fig. 5 (b). The momentum $p^*$ corresponding to the energy $W_p$ of the three-body resonance is determined by

$$p^* = \pm \sqrt{2\eta_N(W_p - E_{\Lambda^*} - m_N)}. \quad (23)$$

If $p^*$ intercepts the contour $C$, we have to take care of the analytic continuation of the $N\Lambda(1405)$ energy sheet. As will be seen in section 4, the trajectories of the three-body resonance in our calculation follow line A of Fig. 5(a) and do not intercept the singularity of the two-body resonance.
III. MODEL OF THE TWO-BODY INTERACTIONS

We take into account the $\bar{K}N$ interactions in $I^\pi = 1/2^-$, $I = 0$ and $I = 1$ states, the $\pi N$ interactions in $J^\pi = 1/2^-$, $I = 1/2$ and $3/2$ states and the $NN$ interaction in $I = 0, 1 S_0$ state. Our s-wave meson-baryon interaction is guided by the leading order effective chiral Lagrangian for the octet baryon $\psi_B$ and the pseudoscalar meson $\phi$ fields given as

$$L_{int} = \frac{i}{8F_\pi^2} tr(\bar{\psi}_B \gamma^\mu [[\phi, \partial_\mu \phi], \psi_B]).$$

The meson-baryon potential derived from the chiral Lagrangian can be written as

$$<\vec{p}', \beta|V_{BM}|\vec{p}, \alpha> = -C_{\beta, \alpha} \frac{1}{(2\pi)^3 8F_\pi^2} \frac{m_\beta + m_\alpha}{\sqrt{4E_\beta(\vec{p}')E_\alpha(\vec{p})}} \times g_\beta(\vec{p}')g_\alpha(\vec{p}).$$

Here $\vec{p}$ and $\vec{p}'$ are the momentum of the meson in the initial state $\alpha$ and the final state $\beta$. The strength of the potential at zero momentum is not an arbitrary constant but is determined by the pion decay constant $F_\pi$. The relative strength between the meson-baryon states is controlled by the constants $C_{\beta, \alpha}$ which are basically determined by the SU(3) flavor structure of the chiral Lagrangian. The parameter of our model is the cutoff $\Lambda$ of the phenomenologically introduced vertex function $g_\alpha(\vec{p}) = \Lambda_\alpha^4/(\vec{p}^2 + \Lambda_\alpha^2)^2$. 
The most important interaction for the study of the $KNN$ system is the $I = 0$ $KN$ interaction. We describe the $KN$ interaction by the coupled-channel model of the $KN$ and the $\pi\Sigma$ states. The constants $C_{\beta,\alpha}$ for this channel are given as $C_{KN-KN} = 6, C_{KN-\pi\Sigma} = -\sqrt{6}$ and $C_{\pi\Sigma-\pi\Sigma} = 8$. The cutoff $\Lambda$ is determined by fitting the scattering length $a_{KN}^{I=0} = -1.70 + i0.68$ fm of Ref. [22]. The values of $\Lambda$ are around 1 GeV and are given as model (a) in Tables I and II for the nonrelativistic and the relativistic models. In general, the form factors of the relativistic models are hard compared with those of the non-relativistic models because of the weak relativistic kinetic energy. We found a resonance pole at $W = 1420 - i30$ MeV for the non-relativistic and the relativistic models. The relativistic kinematics might be important in describing $\pi Y$ channel because of the small pion mass. We choose this model (a) as a standard parameter of the $KN$ interaction.

The $\bar{K}N$ scattering lengths are not very well constrained from the data. The ranges of the $\bar{K}N$ scattering lengths are studied within the chiral unitary model in Ref. [23]. In this work, we simply examined models with the scattering length $a_{KN}^{I=0} = (-1.70\pm0.10) + i(0.68\pm0.10)$ fm in order to examine the sensitivity of the energy of the three-body resonance on the input model of the two-body interaction. The cutoff $\Lambda$’s for those models are given as models (b)-(e) of Tables I and II. The values of the resonance energy are about $1415 \sim 1425$ MeV, and the width $50 \sim 70$ MeV, which are close to the values of the chiral model in Ref. [16]. One can notice that there is a correlation between the real (imaginary) part of the pole energy of the $\Lambda(1405)$ and the imaginary (real) part of the scattering length. Those resonance energies are slightly larger than the pole energy reported in Ref. [24]. Therefore as a last model, model (f) reproduces the deeper resonance energy $1406 - i25$ MeV of Ref. [24]. The scattering length of this model is $-1.72 + i0.44$ fm, which is, however, somewhat different from the value $-1.54 + i0.74$ fm in Ref. [24].

The $I = 1 \bar{K}N$ interaction is described by the $\bar{K}N - \pi\Sigma - \pi\Lambda$ coupled-channel model. The coupling constants $C_{\beta,\alpha}$ are $C_{KN-KN} = 2, C_{KN-\pi\Sigma} = -2, C_{KN-\pi\Lambda} = -\sqrt{6}, C_{\pi\Sigma-\pi\Sigma} = 4$ and $C_{\pi\Sigma-\pi\Lambda} = C_{\pi\Lambda-\pi\Lambda} = 0$. The cutoff $\Lambda$’s are determined to fit the imaginary part of the scattering length of Ref. [22], which are given as model (A) in Tables III and IV for the non-relativistic and the relativistic models. The real part of the scattering length of those models is larger than $a_{KN}^{I=1} = 0.37 + i0.60$ fm of Ref. [22]. The $K^-p$ scattering length predicted from model (aA) , which is model (a) for $I = 0$ and model (A) for $I = 1$ interactions, is between the central values of the two kaonic hydrogen data [25, 26, 27]. To study the sensitivity of
the models of $I = 1$ $KN$ interaction to the resonance energy of $K^-pp$ system, we constructed model (B) given in Tables III and IV. A similar model of $KN$ interaction is developed to study $K^-d$ scattering\[28]. The range of the vertex form factor found in in Ref. \[28\], which is monopole form factor with 880MeV cutoff mass, is comparable to ours.

The total cross sections of $K^-p$ reactions predicted from our models (aA), (aB) and (fA) are shown in Fig. 6 together with the data \[29, 30, 31, 32, 33\]. The models (aA) and (aB) describe well the $K^-p \rightarrow K^-p(Fig. \, 6a)$, $K^-p \rightarrow \pi^+\Sigma^-(Fig. \, 6b)$ and $K^-p \rightarrow \pi^-\Sigma^+(Fig. \, 6c)$ reactions, where both $I = 0$ and $I = 1$ interactions contribute to the cross section. The models of $I = 0$ ($I = 1$) can be tested from $K^-p \rightarrow \pi^0\Sigma^0(Fig. \, 6d)$ ($K^-p \rightarrow \pi^0\Lambda(Fig. \, 6e)$) reactions, where models 'a' and 'A/B' describe the cross sections well. The model (fA) tends to give smaller cross sections. It is noticed, however, as we will see, that the resonance energy of the $K^-pp$ system is more sensitive to the $I = 0$ $KN$ interaction and less sensitive to $I = 1$ interactions, while both $I = 0$ and $I = 1$ interactions are equally important to describe $K^-p$ cross sections and kaonic hydrogen data.

TABLE I: The cutoff parameters, scattering length and the resonance pole of the relativistic models of $I=0 \bar{K}N - \pi\Sigma$ interaction.

The form of the s-wave $\pi N$ interactions is taken as Eq. (25). The constant $C_{\alpha,\beta}$ is 4 for $I = 1/2$ and $-2$ for $I = 3/2$ states. The parameters of the potentials are determined by fitting the scattering length and the low energy phase shifts. For $I = 1/2$ state, the strength of the potential is modified as $\lambda C_{\beta,\alpha}$ by introducing a phenomenological factor $\lambda$ to describe the data of the scattering length (0.1788±0.0050)$m^{-1}$[34] and the phase shifts [35]. The fitted parameters $\lambda$ and $\Lambda$ are shown in Table V together with the scattering length.

For the $I = 3/2$ $\pi N$ scattering, the $\pi N$ potential is constructed so as to reproduce the scattering length $(-0.0927 \pm 0.0093)m^{-1}$ and the $S_{31}$ partial wave phase shifts data.

Here we introduced a modified dipole form factor as

$$
g(\vec{p}) = \frac{\Lambda^4}{(\vec{p}^2 + \Lambda^2)^2} \times (1 + a\vec{p}^2).
$$

(26)

TABLE V: Parameters and scattering length for the relativistic and nonrelativistic model of $I=1/2$ $\pi N$ interaction.

The parameters of the model are $\Lambda$ and $a$ for the form factor and the strength parameter $\lambda$. The obtained parameters are summarized in Table VII. The relativistic model can describe well the phase shifts up to 1.2 GeV as shown in Fig. 7; however, the non-relativistic model starts to deviate from the data at around 1.1 GeV.

We used a Yamaguchi-type separable interaction for the nucleon-nucleon potential. To take into account the long range attractive interaction and the short range repulsion of the two-nucleon interaction, we used a two-term separable potential,

$$<\vec{p}'|V_{BB}|\vec{p}> = C_{RG}g_R(\vec{p}) g_R(\vec{p}) - C_{A}g_A(\vec{p}) g_A(\vec{p}).$$  \hspace{1cm} (27)
Here $C_R$ ($C_A$) is the coupling strength of the repulsive (attractive) potential. $g_R(\vec{p})$ ($g_A(\vec{p})$) is the form factor, whose form is given as $g_R(\vec{p}) = \Lambda_R^2 / (\vec{p}^2 + \Lambda_R^2)$ ($g_A(\vec{p}) = \Lambda_A^2 / (\vec{p}^2 + \Lambda_A^2)$), where $\Lambda$ is a cutoff of the nucleon-nucleon potential. The adjustable parameters in our nucleon-nucleon potential are determined by fits to the data of the $^1S_0$ phase shifts. The best-fit parameters are summarized in Table VI. The low energy phase shifts of the $^1S_0$ state is shown in Fig. 8.

| $\lambda$ | $\Lambda$ (MeV) | $a$ (fm$^2$) | scattering length |

**TABLE VII:** Our parameters of the relativistic and nonrelativistic model for $NN$ scattering.
IV. RESULTS AND DISCUSSION

The dibaryon resonance with $J^\pi = 0^-, S = -1, I = 1/2$ is studied using a formalism of the Faddeev equation as explained in section 2. We assume all the angular momentum to be in an s-wave state and the spin singlet state $S_{BB} = 0$ for the two baryon states. We have included the dominant $\bar{K}NN, \pi \Sigma N$ and $\pi \Lambda N$ Fock-space components, whose isospin wave functions are $[\bar{K} \otimes [NN]_{I=1/2}]_{I=1/2}$, $[\pi \otimes [\Sigma N]_{I=1/2,3/2}]_{I=1/2}$ and $[\pi \otimes [\Lambda N]_{I=1/2}]_{I=1/2}$. An approximation within this model is that the weak $YN$ interaction is not included.

Let us start to examine the three-body resonance energy by taking into account only the $\bar{K}N$ interactions $v_{\bar{K}N-KN}^{I=0,1}$ neglecting the $\pi YN$ Fock space. In this case, the bound state pole is expected to lie on the physical Riemann sheet below $m_K + 2m_N$ if the $\bar{K}N$ attraction is strong enough. Therefore it is not necessary to use the analytic continuation of the amplitude with the deformed contour discussed in section 2, so we simply use the integral over the momentum $p_i$ in the real axis. The results are shown in Fig. 9 marked by $a$ and $a'$ for the the 'relativistic' and 'non-relativistic' models. Here we use the 'standard' parameters (aA) of the $\bar{K}N$ interaction with nonrelativistic and relativistic kinematics. The binding energies are about 18 MeV. The $\bar{K}N$ interaction included in $\tau$ and $Z$ is strong enough to bind the $\bar{K}NN$ system, where the $I = 0 \bar{K}N$ interaction plays a dominant role. We then take into account the $NN$ interaction. Then the binding energy increased furthermore to 25.1 MeV (22.8 MeV) shown as $b$ ($b'$) for 'relativistic' ('nonrelativistic') model. Notice that
FIG. 9: The pole trajectories of the $\bar{K}NN - \pi YN$ scattering amplitude for the $J^\pi = 0^-$ and $I = 1/2$ state. The solid curve and the filled circles (dashed curve and filled triangles) show the results of the relativistic (nonrelativistic) model (aA). Here $W_{KNN} = m_K + 2m_N$.

if we neglect the repulsive component of the $NN$ interaction, we obtain a much more deeply bound state.

In the next step, we gradually include the $\pi YN$ interactions, while the pion-exchange $Z$ diagram is not yet included. To do this, we multiply by factor $x$ the coupling constants $C_{\alpha,\beta}$ of the $\bar{K}N - \pi Y$ and $\pi Y - \pi Y$ interactions as $xC_{\alpha,\beta}$. When the parameter is zero, $x = 0$, the $\pi Y$ is disconnected from $\bar{K}N$ and when it takes the value 1, $x = 1$, we recover the full model. By varying the parameter $x$ from 0 to 1, we can follow the trajectory of the resonance pole from the bound state pole. Now the $\bar{K}NN$ bound state decays into the $\pi YN$ channel and the bound state pole moves into the unphysical sheet. Since the $\bar{K}NN$ bound state was found above the $\pi \Sigma N$ threshold, the resonance pole may be on the $\pi YN$ unphysical and $\bar{K}NN$ physical Riemann sheet, which we have discussed in section 2. The results of the pole trajectories are shown by the solid and dashed curves in Fig. 9 corresponding to the relativistic and the nonrelativistic models. Increasing the coupling to the $\pi YN$ channel causes the width as well as the binding energy of the resonance increases. For larger binding energy $Re(W_{\text{pole}} - W_{KNN}) < -60$ MeV the width starts to decrease because of the decreasing phase space for the decay into the $\pi \Sigma N$ state. The pole position is at $-82 - i29$ MeV ($-91 - 28i$) for the relativistic (nonrelativistic) model shown as $c(c')$. It is noticed that the numerical method to follow the pole trajectories helps us to find whether
we encounter singularities or not. As an example, the pole of the three-body resonance is shown by the solid line in Fig. 10 for $0 < x < 1$. The pole of the $\Lambda(1405)$ is also shown by the dashed curve. The trajectory of the $\bar{K}NN$ resonance is similar to the the case A in Fig. 5, and the integration contour does not intercept the singularity arising from the two-body resonance $\Lambda(1405)$.

Finally we include the $\pi$ exchange mechanism in $Z$ and $\pi N$ two-body scattering terms in $\tau$, which adds another mechanism for the decay of the $\bar{K}NN$ into $\pi YN$ and is important for the width of the three-body resonance. The final results of the $\bar{K}NN - \pi YN$ resonance poles are denoted by $d$ and $d'$ in Fig. 9. This mechanism increases the width of the three-body resonance by about 14 MeV, while the effect on the real part is small. The cancellation between the attractive $I = 1/2$ $\pi N$ interaction and the repulsive $I = 3/2$ $\pi N$ interaction may lead to the small effects on the real part of the resonance energy. The effects of $\pi \Lambda N$ channel is small which increases binding energy and half-width at most by 1MeV. The pole position of the three-body resonance is $W = M - i\Gamma/2 = 2m_N + m_K - 79.3 - i37.1$ MeV ($2m_N + m_K - 92.2 - i35.4$ MeV) for relativistic (nonrelativistic) model shown as $d$ and $d'$.

The model dependence of our results on the three-body resonance is summarized in Tables VIII and IX. The $\bar{K}NN - \pi YN$ resonance pole is located on the $\bar{K}NN$ physical and $\pi YN$ unphysical sheet with the binding energy, $B \sim 60 - 95$ MeV, and the width, $\Gamma \sim 45 - 80$ MeV, using relativistic models. All of our models predict resonance energies above the $\pi \Sigma N$ threshold. The relatively large model dependence of our results is due to the uncertainty in the models of $I = 0 \bar{K}N - \pi \Sigma$ interaction. Comparing the results of model (A) with
|       | Model (A) | Model (B) |
|-------|-----------|-----------|
| (a)   | $-79.3 - i37.1$ | $-79.3 - i37.3$ |
| (b)   | $-93.3 - i27.4$ | $-93.3 - i27.6$ |
| (c)   | $-57.2 - i38.6$ | $-56.9 - i38.6$ |
| (d)   | $-72.4 - i31.7$ | $-72.2 - i31.9$ |
| (e)   | $-87.1 - i40.8$ | $-87.1 - i41.0$ |
| (f)   | $-63.3 - i22.2$ | $-63.2 - i22.3$ |

**TABLE VIII:** The pole energy ($W_{pole} - m_K - 2m_N$) of the three-body resonance using relativistic models. The listed pole energies in MeV can be related to binding energy $B$ and the width $\Gamma$ as $W_{pole} - m_K - 2m_N = -B - i\Gamma/2$.

|       | Model (A) | Model (B) |
|-------|-----------|-----------|
| (a)   | $-92.2 - i35.4$ | $-92.3 - i35.6$ |
| (b)   | $-101.6 - i20.7$ | $-101.6 - i20.7$ |
| (c)   | $-72.7 - i53.9$ | $-72.5 - i54.9$ |
| (d)   | $-83.0 - i33.3$ | $-83.0 - i33.6$ |
| (e)   | $-98.1 - i33.2$ | $-98.2 - i33.3$ |
| (f)   | $-66.5 - i24.4$ | $-66.3 - i24.4$ |

**TABLE IX:** The pole energy of the three-body resonance. The same as Table VIII but for the nonrelativistic models.

model (B), we can see the three-body pole position is almost independent of the parameters of the $I = 1 \bar{K}N - \pi Y$ interaction. By varying the real(imaginary) part of the fitted scattering length by $\pm 0.1$ fm, the binding energy of the three-body resonance is affected by $\sim \pm 14(8)$ MeV. Following another way to construct the model, the parameters of the model (f) are fitted to the pole energy of the $\Lambda(1405)$. This model predicts the scattering length $-1.72 + i0.44$ fm. The energy of the three-body resonance is found to be $B = 63$ MeV with a rather small width, $\Gamma = 44$ MeV, compared with the models (a-e), which can already be seen in the small imaginary part of the scattering length in model (f).

Let us briefly compare our results with those of the other theoretical studies of the $K^-pp$
resonance, which use a nonrelativistic approach. Our resonance has a deeper binding energy and a similar width compared with those in Ref. [4]. However, it is not straightforward to compare with the pole energy of Ref. [4] because of the differences in the method to obtain the three-body resonance energy and on the model for the $\bar{K}N$ interaction. Their $\bar{K}N$ potential is stronger and has a short range than ours. Recently Shevchenko, Gal and Mares [19] studied $K^-pp$ system using the nonrelativistic coupled-channel Faddeev equation. Though the details of their method is not described in Ref. [19], it seems their approach is quite similar to our present study. They employed a phenomenological $\bar{K}N$ potential model, and reported $B \sim 55 - 70$ MeV and $\Gamma \sim 95 - 110$ MeV. Their result is consistent with our results of the nonrelativistic model. Specially our result using the model (c) gives a quite similar resonance energy and width.

In summary we have studied the existence and properties of a strange dibaryon resonance using the $\bar{K}NN - \piYN$ coupled channel Faddeev equation. By solving the three-body equation the energy dependence of the resonant $\bar{K}N$ amplitude is fully taken into account. The resonance pole has been investigated from the eigenvalue of the kernel with the analytic continuation of the scattering amplitude on the unphysical Riemann sheet. The model of the $\bar{K}N - \piY$ interaction is constructed from the leading order term of the chiral Lagrangian takes into account the relativistic kinematics. The $\bar{K}N$ interaction parameters are fitted to the scattering length given by Martin. We found a resonance pole at $B \sim 79$ MeV and $\Gamma \sim 74$ MeV in the relativistic model (aA). However, as the $\bar{K}N$ interaction is not very well constrained by the data, we studied a possible range of the resonance energies by considering different parameter sets of the $\bar{K}N - \piY$ interaction. The binding energy and the full width can be in the range of $B \sim 60 - 95$ MeV and $\Gamma \sim 45 - 80$ MeV when computed in the relativistic model. In order to connect the resonance found in this work to the experimental signal, further theoretical studies on the production mechanism and further decay of the resonance especially to the $\Lambda - p$ channel are necessary.

The authors are grateful to Prof. A. Matsuyama for very useful discussions on the three-body resonance. We also thank Drs. B. Juliá-Díaz, T.-S. H. Lee and Prof. A. Gal for discussions. This work is supported by a Grant-in-Aid for Scientific Research on Priority
APPENDIX

The spin-isospin recoupling coefficient of the particle exchange interaction $Z$ is briefly explained. The coefficient given in Eq. (1.181) of Ref. [21] can be simplified for s-wave states. The three-body state with total spin and isospin $(S_{tot}, I_{tot})$, which couples with baryon 'isobar' with spin and isospin $(S, I)$ and the spectator baryon $B_i(S_i, I_i)$, is given as

$$[[M_3(S_3, I_3) \otimes B_j(S_j, I_j)](S, I) \otimes B_i(S_i, I_i)](S_{tot}, I_{tot}) >.$$  \hspace{1cm} (A.1)

Here baryon $i, j$ represents particle 1 or 2, and the meson is always assigned as the third particle. The wave function of the three-body state, which couples with dibaryon 'isobar' and the spectator meson $M_3$, is given as

$$[[B_1(S_1, I_1) \otimes B_2(S_2, I_2)](S, I) \otimes M_3(S_3, I_3)](S_{tot}, I_{tot}) >.$$  \hspace{1cm} (A.2)

Then Eq. (7) is extended to include spin-isospin degrees of freedom. The particle exchange interaction for the spectators $l, m$, the isobars $f', f$ with spin-isospin $(S', I')$ and $(S, I)$ and the exchanged particle $n$ can be expressed as follows

$$Z_{i, f'(S', I'), m, f(S, I)}(p_l, p_m, W) = R_{i, f'(S', I'), m, f(S, I)} \int d(\hat{p}_l \cdot \hat{p}_m) \frac{2\pi g_f(s', I')(q_l)g_f(s, I)(q_m)}{W - E_l(p_l) - E_m(p_m) - E_n(\hat{p}_l + \hat{p}_m)},$$  \hspace{1cm} (A.3)

where $f$ represents isobar $Y_K, Y_\pi, d$ and $N^*$.

$R_{i, f'(S', I'), m, f(S, I)}$ is given by the overlap of the initial and final spin-isospin wave functions.

For the meson($M_3$) exchange mechanism, $R_{i, f'(S', I'), j, f(S, I)}$ is given as,

$$R_{i, f'(S', I'), j, f(S, I)} = \frac{\langle [[M_3(S_3, I_3) \otimes B_j(S_j, I_j)](S', I') \otimes B_i(S_i, I_i)](S_{tot}, I_{tot}) \rangle}{\langle [[M_3(S_3, I_3) \otimes B_i(S_i, I_i)](S, I) \otimes B_j(S_j, I_j)](S_{tot}, I_{tot}) \rangle} \times \langle [[M_3(S_3, I_3) \otimes B_i(S_i, I_i)](S, I) \otimes B_j(S_j, I_j)](S_{tot}, I_{tot}) \rangle >$$

$$= (-1)^{S + S' - S_{tot}} W(S_1, S_3, S_{tot}; S_j, S, S') \sqrt{(2S + 1)(2S' + 1)}$$

$$\times (-1)^{I + I' - I_{tot}} W(I_i, I_3, I_{tot}; I_j, I, I') \sqrt{(2I + 1)(2I' + 1)}. \hspace{1cm} (A.4)$$
For the baryon($B_j$) exchange mechanism, $R_{i,f'(S',I'),3,f(S,I)}$ is given as,

$$R_{i,f'(S',I'),3,f(S,I)} = \langle \left[ M_{3}(S_3,I_3) \otimes B_{j}(S_j,I_j) \right] (S',I') \otimes B_{i}(S_i,I_i) \rangle_{(S_{tot},I_{tot})}$$

$$\times \langle \left[ B_{i}(S_i,I_i) \otimes B_{2}(S_{2},I_{2}) \right] (S,I) \otimes M_{3}(S_3,I_3) \rangle_{(S_{tot},I_{tot})} >$$

$$= (-1)^{S_3+S_{tot}+I_3+I-I_{tot}} W(S_3, S_j, S_{tot}, S_{i}; S', S) \sqrt{(2S'+1)(2S+1)}$$

$$\times W(I_3, I_j, I_{tot}, I_i; I') \sqrt{(2I'+1)(2I+1)}$$

$$\times (\delta_{i,2}\delta_{j,1} + \delta_{i,1}\delta_{j,2}(-1)^{S_i+S_j-S+I_i+I_j-I}).$$

(A.5)

When we anti-symmetrize the AGS equation, the last factor in the bracket in Eq. (A.5) projects the anti-symmetric two nucleon states. This can be explicitly seen by comparing the exchange of nucleon 2 $Z_2,Y_K(S',I'),3,d(S,I)$ and nucleon 1 $Z_1,Y_K(S',I'),3,d(S,I)$ interactions. Using Eq. (A.5), those interactions are related as

$$R_{1,Y_K(S',I'),3,d(S,I)} = (-1)^{S+I} R_{2,Y_K(S',I'),3,d(S,I)},$$

(A.6)

which leads to Eq. (17) as

$$X_{Y_K,Y_K} = (1 - (-1)^{S+I}) Z_{Y_K,d7d,d} X_{d,Y_K} + \cdots.$$
