Centro de Física Computacional, Universidade de Coimbra, 3004-516 Coimbra, Portugal

We study the Landau gauge gluon propagator at zero and finite temperature using lattice simulations. Particular attention is given to the finite size effects and to the infrared behaviour.

PACS numbers: 11.15.Ha; 12.38.Gc

1. The gluon propagator at zero temperature

In lattice QCD, the finite lattice spacing and finite lattice volume effects on the gluon propagator can be investigated with the help of lattice simulations at several lattice spacings and physical volumes. Here we report on such a calculation. For details on the lattice setup see [1].

In figure 1, we show the renormalized gluon propagator at $\mu = 4$ GeV for all lattice simulations. Note that we compare our data with the large volume simulations performed by the Berlin-Moscow-Adelaide collaboration [2] – see [1] for details. In each plot we show data for a given value of $\beta$, i.e. data in the same plot has the same lattice spacing. The plots show that, for a given lattice spacing, the infrared gluon propagator decreases as the lattice volume increases. For larger momenta, the lattice data is less dependent on the lattice volume; indeed, for momenta above $\sim 900$ MeV the lattice data define a unique curve.

We can also investigate finite volume effects by comparing the renormalized gluon propagator computed using the same physical volume but different $\beta$ values. We are able to consider 4 different sets with similar physical volumes — see figure 2. Although the physical volumes considered do not match perfectly, one can see in figure 2 that for momenta above $\sim 900$ MeV the lattice data define a unique curve. This means that the

Fig. 1. Renormalized gluon propagator for $\mu = 4$ GeV for all lattice simulations.

Renormalization procedure has been able to remove all dependence on the ultraviolet cut-off $a$ for the mid and high momentum regions. However, a comparison between figures 1 and 2 shows that, in the infrared region, the corrections due to the finite lattice spacing seem to be larger than the corrections associated with the finite lattice volume. In particular, figure 2 shows that the simulations performed with $\beta = 5.7$, i.e., with a coarse lattice spacing, underestimate the gluon propagator in the infrared region. In this sense, the large volume simulations performed by the Berlin-Moscow-Adelaide collaboration provide a lower bound for the continuum infrared propagator.

2. The gluon propagator at finite temperature

We also aim to study how temperature changes the gluon propagator. At finite temperature, the gluon propagator is described by two tensor structures,

$$ P_{\mu \nu}^{ab}(q) = \delta^{ab} \left( P_T^{\mu \nu} D_T(q, \vec{q}) + P_L^{\mu \nu} D_L(q, \vec{q}) \right) $$

(1)
where the transverse and longitudinal projectors are defined by

\[ P_{\mu\nu}^T = (1-\delta_{\mu4})(1-\delta_{\nu4}) \left( \delta_{\mu\nu} - \frac{q_\mu q_\nu}{q^2} \right) \quad P_{\mu\nu}^L = \left( \delta_{\mu\nu} - \frac{q_\mu q_\nu}{q^2} \right) - P_{\mu\nu}^T ; \quad (2) \]

the transverse \( D_T \) and longitudinal \( D_L \) propagators are given by

\[ D_T(q) = \frac{1}{2V(N_c^2 - 1)} \left( \langle A^a_i(q)A^a_i(-q) \rangle - \frac{q_4^2}{q^2} \langle A^a_i(q)A^a_i(-q) \rangle \right) \quad (3) \]

\[ D_L(q) = \frac{1}{V(N_c^2 - 1)} \left( 1 + \frac{q_4^2}{q^2} \langle A^a_i(q)A^a_i(-q) \rangle \right) \quad (4) \]

On the lattice, finite temperature is introduced by reducing the temporal extent of the lattice, i.e. we work with lattices \( L_s^3 \times L_t \), with \( L_t \ll L_s \). The temperature is defined by \( T = 1/aL_t \).

In table 2 we show the lattice setup of our simulation. Simulations in this section have been performed with the help of Chroma library [4]. For the determination of the lattice spacing we fit the string tension data in [3].
Table 1. Lattice setup used for the computation of the gluon propagator at finite
temperature.

| Temp. (MeV) | $\beta$  | $L_a$ | $L_t$ | $a$ [fm] | $1/a$ (GeV) |
|-------------|----------|-------|-------|----------|-------------|

in order to have a function $a(\beta)$. Note also that we have been careful in the
choice of the parameters, in particular we have only two different spatial
physical volumes: $\sim (3.3 \text{fm})^3$ and $\sim (6.5 \text{fm})^3$. This allows for a better
control of finite size effects.

Figures 3 and 4 show the results obtained up to date. We see that the
transverse propagator, in the infrared region, decreases with the temperature.
Moreover, this component shows finite volume effects; in particular,
the large volume data exhibits a turnover in the infrared, not seen at the
small volume data. The longitudinal component increases for temperatures
below $T_c \sim 270 \text{ MeV}$. Then the data exhibits a discontinuity around $T_c$, and
the propagator decreases for $T > T_c$. The behaviour of the gluon propagator
as a function of the temperature can also be seen in the 3d plots shown
in figure 5.

As shown above, data for different physical (spatial) volumes exhibits
finite volume effects. This can be seen in more detail in figure 6 where we
show the propagators for two volumes at $T=324$ MeV. Moreover, we are
also able to check for finite lattice spacing effects at $T=305$ MeV, where
we worked out two different simulations with similar physical volumes and
temperatures, but different lattice spacings. For this case, it seems that
finite lattice spacing effects are under control, with the exception of the
zero momentum for the transverse component – see figure 7.

Our results show that a better understanding of lattice effects is needed
before our ultimate goal, which is the modelling of the propagators as a
function of momentum and temperature.
