(Dated: November 16, 2017)

A rare decay $K_L \to \mu^+\mu^-$ has been measured precisely, while a rare decay $K_S \to \mu^+\mu^-$ will be observed by an upgrade of the LHCb experiment. Although both processes are almost CP-conserving decays, we point out that an interference contribution between $K_L$ and $K_S$ in the kaon beam emerges from a genuine direct CP violation. It is found that the interference contribution can change $K_S \to \mu^+\mu^-$ standard-model predictions at $\mathcal{O}(60\%)$. We also stress that an unknown sign of $A(K_L \to \gamma\gamma)$ can be determined by a measurement of the interference, which can much reduce a theoretical uncertainty of $\mathcal{B}(K_L \to \mu^+\mu^-)$. We also investigate the interference in a new physics model, where the $\epsilon'_K/\epsilon_K$ tension is explained by an additional Z-penguin contribution.

Keywords: rare kaon decay, direct CP violation

Rare kaon decays have played a crucial role in flavor physics; now this physics program is even more exciting due to the NA62 experiment at CERN, which aims to reach a precision of 10% in $\mathcal{B}(K^+ \to \pi^+\nu\bar{\nu})$ compared to the standard model (SM) in 2018 [1, 2], and the KOTO experiment at J-PARC, which aims, as a first step, at measuring $\mathcal{B}(K_L \to \pi^0\nu\bar{\nu})$ around the SM sensitivity [3–5]. The LHCb experiment also has an impressive kaon physics program [6]. New physics motivated from the $\epsilon'_K/\epsilon_K$ tension [7–9] or $B$-physics anomalies may be tested in rare kaon decays too. Experimentally kaons in two muons in the final state can be considered gold channels, and this motivates theoretical studies.

Within the SM, the branching ratios are predicted to be [10–12]

$$\mathcal{B}(K_L \to \mu^+\mu^-)_{\text{SM}} = \begin{cases} (6.85 \pm 0.80 \pm 0.06) \times 10^{-9} (+), \\ (8.11 \pm 1.49 \pm 0.13) \times 10^{-9} (-), \end{cases}$$

(1)

$$\mathcal{B}(K_S \to \mu^+\mu^-)_{\text{SM}} = (4.99 \text{ (LD)} + 0.19 \text{ (SD)}) \times 10^{-12} = (5.18 \pm 1.50 \pm 0.02) \times 10^{-12},$$

(2)

where the first uncertainty comes from long-distance contributions and the second one denotes remaining theoretical uncertainties including the Cabibbo-Kobayashi-Maskawa (CKM) parameters. The long-distance (short-distance) contribution to $\mathcal{B}(K_S \to \mu^+\mu^-)_{\text{SM}}$ is indicated by LD (SD). Here, the leading chiral contribution at $\mathcal{O}(p^4)$, $K_S \to \pi^+\pi^- \to \gamma\gamma \to \mu^+\mu^-$, is theoretically clean [10, 13]: $K_S \to \pi^+\pi^-$ is described in terms of $G_8$ (and $G_{27}$) which represents the leading coupling of the $|\Delta S| = 1$ nonleptonic weak Lagrangian [14] and $\text{sgn}(G_8) < 0$ is taken; we just assume the sign predicted by the $|\Delta S| = 1$ partonic Lagrangian computing the hadronic matrix elements of four-quark operators in the large-$N_C$ limit (or employing naive factorization) [11, 15, 16]. The values of Eqs. (1) and (2) are based on the best-fit result for the CKM parameters in Ref. [17]. One should note that $\mathcal{B}(K_L \to \mu^+\mu^-)_{\text{SM}}$ depends on an unknown sign of $A(K_L \to \gamma\gamma)$. Indeed, differently from the previously discussed $K_S$ decay, the leading $\mathcal{O}(p^4)$ of $A(K_L \to \gamma\gamma \to \mu^+\mu^-)$ given by the Wess-Zumino anomaly [18] is vanishing due to the delicate cancellation enforced by the Gell-Mann–Okubo formula of the two contributions with $\pi^0$ and $\eta$ exchanges [14, 19]. Higher chiral orders spoil this cancellation and unfortunately also the cleanness of the prediction even of the sign of $A(K_L \to \gamma\gamma)$ [15, 16]. When $\text{sgn}(A(K_L \to \gamma\gamma)) = \pm \text{sgn}(A(K_L \to (\pi^0)^* \to \gamma\gamma))$, we represent $+$ or $-$ in Eq. (1). The choice of $+$ (−) gives a destructive (constructive) interference between short- and long-distance contributions to $\mathcal{B}(K_L \to \mu^+\mu^-)$ in the SM [15, 16].

On the other hand, experimental results are [20]

$$\mathcal{B}(K_L \to \mu^+\mu^-)_{\text{exp}} = (6.84 \pm 0.11) \times 10^{-9},$$

(3)

and the 90% C.L. upper bound is [21]

$$\mathcal{B}(K_S \to \mu^+\mu^-)_{\text{exp}} < 0.8 \times 10^{-9}.$$  

(4)

Although a current bound of $\mathcal{B}(K_S \to \mu^+\mu^-)$ is weaker than the SM prediction by 2 orders of magnitude, an upgrade of the LHCb experiment is aiming to reach the SM sensitivity, specifically, the LHC Run 3 (from 2021) [22]. Note that the branching ratios into the electron mode are suppressed by $m^2/\mu^2$, and the detector sensitivity to the electron mode in the LHCb is weaker than the muonic mode.

Equations (1) and (2) are predictions of pure $K_L$ and $K_S$ initial states, respectively. In this Letter, we focus on interference between $K_L$ and $K_S$ states,

$$\Gamma(K \to f)_{\text{int}} \propto A(K_S \to f)^* A(K_L \to f),$$

(5)

where the initial state is the same $K^0$ (or $\bar{K}^0$), and a lifetime of this contribution is $2\tau_S$. Such an interference
contribution is first discussed in Refs. [23, 24], and has been observed and utilized in many processes, e.g., \( K \to \pi \pi [25], K \to 3\pi^0 [26, 27], K \to \pi^+\pi^-\pi^0 [28], \) and \( K \to \pi^0 e^+ e^- [29] \).

**INTERFERENCE BETWEEN \( K_L \) AND \( K_S \)**

We first review the interference contribution briefly; then, we investigate the numerical impact in the mode of \( \mu^+\mu^- \) in the SM. A state of \( K^0 \) (or \( \bar{K}^0 \)) at \( t = 0 \), which is produced by, e.g., \( pp \to K^0K^-\pi^+ \), evolves into a mixture of \( K_1 \) (CP-even) and \( K_2 \) (CP-odd) states, \( \bar{K}^0(t) = \frac{1}{\sqrt{2(1 + \epsilon)}} e^{-iH_{s,t}(K_1 + \bar{c}[K_2])} \pm e^{-iH_{s,t}[(K_2 + \bar{c}[K_1])]} \), \( \epsilon \) is a CP-violating parameter

where \( H_{s,t} = M_{L,S} - (i/2)\Gamma_{L,S}, |K_{1,2}| = (1/\sqrt{2})(|K^0| \pm |\bar{K}^0|), \) and \( CP|K_{1,2}| = \pm K_{1,2} \). The CP impurity parameter \( \epsilon \) is related to \( \epsilon_K \) as \( \epsilon_K = \bar{\epsilon}(\bar{\epsilon} + \text{Im} A_0/\text{Re} A_0)/(1 + i\text{Im} A_0/\text{Re} A_0) \) with \( A|K^0 \to (\pi\pi)_{I=0} \equiv A_0 e^{i\delta_0}, \) and \( \delta_0 \) is a strong phase for an \( I = 0 \) two-pion state.

The decay intensity of a neutral kaon beam into \( f \) is

\[
I(t) = 1 + \frac{D}{2} \left| (f - \Re[A_{K^0}])^{\Delta s = 1}|K^0(t)| \right|^2 + \frac{D}{2} \left| (f - \Re[A_{\bar{K}^0}])^{\Delta s = 1}|\bar{K}^0(t)| \right|^2
\]

where \( M_L - M_S \equiv \Delta M_{K^0} > 0, A_{K(1,2)} \equiv A_{(1,2) \to f} \), and a dilution factor \( D \) is a measure of the initial (\( t = 0 \)) asymmetry of the number of \( K^0 \) and \( \bar{K}^0 \),

\[
D = \frac{K^0 - \bar{K}^0}{K^0 + \bar{K}^0}
\]

The term proportional to \( \exp(-\Gamma_{s,t}) \) [or \( \exp(-\Gamma_{s,t}) \)] arises from \( K_S \) (or \( K_L \)) decay in the mode \( f \), while the term proportional to \( \exp[-(\Gamma_S + \Gamma_L)/2] \) represents the interference between \( K_L \) and \( K_S \), whose lifetime is \( 2/(\Gamma_S + \Gamma_L) \simeq 2\tau_S \).

**INTERFERENCE EFFECT ON \( K \to \mu^+\mu^- \) IN THE SM**

In the case when \( f = \mu^+\mu^- \), all \( \mathcal{O}(\bar{\epsilon}) \) terms are numerically negligible, which is certainly different situation from \( K \to 2\pi \) and \( K \to 3\pi \). Then, a term of Eq. \((5)\) is relevant, which is the first term in the second line of Eq. \((8)\). The \( |A_{K(1,2)}|^2 \) term provides the SM prediction of \( B(K_{S,L} \to \mu^+\mu^-)_{\text{SM}} \) in Eqs. \((1)\) and \((2)\) \cite{10–12}, which is significantly dominated by a CP-conserving long-distance contribution. Within the SM, regarding the interference term, we obtain

\[
\sum_{\text{spin}} A_{K_1 \to \mu^+\mu^-} A_{K_2 \to \mu^+\mu^-} = 16iG_F^2 M_W^4 F_2^2 M_\mu^2 \sin^2 \theta_W \text{Im}[\alpha_i(y_{\gamma A})] + \epsilon \lambda \theta \epsilon \bar{\epsilon} \lambda \theta \epsilon \text{Im}[\alpha_i(y_{\gamma A})] + \epsilon \lambda \theta \epsilon \bar{\epsilon} \lambda \theta \epsilon \text{Im}[\alpha_i(y_{\gamma A})]
\]

where the spin of the muons is summed up as \( \lambda_q \equiv V_{q0}V_{q0}, \sin^2 \theta_W \equiv \sin^2 \theta_{\text{WS}}(M_Z) = 0.23129(5) [20], f_K = \sqrt{2F_K} = 0.1556(4) \text{GeV} [20], \) the top-quark contribution in next-to-leading order of QCD is \( y_{\gamma A}^t = -0.654(34) [12, 30] \) (which is defined in the next section), the charm-quark contribution in next-to-next-to-leading order of QCD is \( y_c = -2.03(32) \times 10^{-4} [12] \), and an amplitude of the CP-conserving long-distance contributions for \( K_2 \) is \cite{11, 31}

\[
A_{K_{\gamma A}}^c = \frac{\pm 2\pi \alpha_0}{G_F^2 M_W^4 F_2 M_\mu} \sqrt{\frac{\pi}{M_\mu}} \Gamma(K_L \to \gamma\gamma)_{\exp} \times (\epsilon_{\text{disp}} + \epsilon_{\text{abs}}) = \pm 2.01(1) \times 10^{-4} \times (0.71(101) - i5.21),
\]

where \( A_{K_2}^2 = \epsilon_{\text{disp}} + \epsilon_{\text{abs}} [31], \) where \( A(s) \) given in Refs. \cite{32, 33} denotes contributions from \( 2\gamma \) intermediate state and its counterterm, and \( \text{disp} \) (abs) indicates the dispersive (absorptive) contribution, \( B(K_L \to \gamma\gamma)_{\exp} = 5.47(4) \times 10^{-4} [20] \) and \( \alpha_0 = 1/137.04. \) Here, the sign ambiguity in \( A_{K_{\gamma A}}^c \) comes from the unknown sign of \( A(K,L_\to \gamma\gamma), \) and this \( \pm \) corresponds to \( \text{sgn}[A(K_L \to \gamma\gamma)] = \pm \text{sgn}[A(K_L \to (\pi^0)^\tau \to \gamma\gamma)] \) and Eq. \((1)\). Obviously, the interference in Eq. \((10)\) is proportional to the direct CP-violating contribution.

Figure 1 shows a time distribution of \( K \to \mu^+\mu^- \) in Eq. \((8)\) with several choices of \( D \) and the sign of \( A_{K_{\gamma A}}^c \), which are normalized by an integrated decay intensity from \( 0.1\tau_S \) to \( 1.45\tau_S \) (solid lines) and to \( 3\tau_S \) (dashed lines) with \( D = 0 \). It is shown that the interference effect emerges prominently around \( t \simeq 0 \), which can give \( \mathcal{O}(10\%) \) difference. Another important point found here
is that one can probe the unknown sign of $A_{L\gamma\gamma}^\mu$ by precise measurement of the interference correction.

Using the result of Eq. (8), let us define an effective branching ratio into $\mu^+\mu^-$, which includes the interference correction and would correspond to event numbers in experiments after a removal of the $K_L$ background,

$$B(K_S \to \mu^+\mu^-)_{\text{eff}} = \tau_S \int_{t_{\text{min}}}^{t_{\text{max}}} dt \left( \frac{\Gamma(K_1)e^{-\Gamma_S t}}{8\pi M_K} + \frac{D}{M_K^2} \sum_{\text{spin}} \text{Re} \left[ e^{-i\Delta M_K t}(A(K_1)^*A(K_2)) e^{-\frac{\Gamma_S + \Gamma_L}{2} t} \right] \right) \varepsilon(t) \right) \right)^{-1},$$

where $\Gamma(K_1) = \Gamma(K_1 \to \mu^+\mu^-)$, $t_{\text{min}}$ to $t_{\text{max}}$ corresponds to a range of detector for $K_S$ tagging, and $\varepsilon(t)$ is a decay-time acceptance of the detector. Note that $B(K_S \to \mu^+\mu^-)_{\text{eff}} = B(K_S \to \mu^+\mu^-)_{\text{SM}}$ in Eq. (2) is obtained when $D = 0$ is chosen. For the removal of the $K_L$ background, the experimental result of $K_L \to \mu^+\mu^-$ in Eq. (3) can be utilized. The LHCb also measures $K_S \to \pi^+\pi^-$ decay as a normalization mode; then, the number of produced $K_S$ can be derived. The number of produced $K_D$ is the same as $K_S$ to a good approximation, so that using the experimental value in Eq. (3) one can estimate and subtract the $K_L \to \mu^+\mu^-$ background [34]. This procedure is independent of $D$, whose dependence appears from $O(\varepsilon)$.

We investigate the effective branching ratio in Eq. (12) as a function of $D$ in Fig. 2. Here, the experimental setup of the LHCb detector is adopted: the decay-time acceptance is $\varepsilon(t) = \exp(-\beta t)$, where $\beta \approx 86$ (ns)$^{-1}$ [35]. The range of the detector for selecting $K \to \mu^+\mu^-$ is $t_{\text{min}} = 8.95$ ps $= 0.1\tau_S$ and $t_{\text{max}} = 130$ ps $= 1.45\tau_S$ [35]. Gray bands represent $B(K_S \to \mu^+\mu^-)_{\text{SM}}$ in Eq. (2). The blue and red lines are the SM predictions, where the lighter (darker) bands stand for uncertainty from $A_{S\gamma\gamma}^\mu$ [from the interference term in Eq. (10)], which is an amplitude of the $CP$-conserving long-distance contributions for $K_1$ [10, 11, 31],

$$A_{S\gamma\gamma}^\mu = \frac{\pi\alpha_0}{G_F^2 M_W^2 F_K M_K[H(0)]^{\frac{1}{2}}} \sqrt{\frac{\pi}{M_K}} \frac{\Gamma(K_S \to \gamma\gamma)_{\text{exp}}}{\Gamma(K_S \to \gamma\gamma)_{\text{SM}}} \times (I_{\text{disp}} + iI_{\text{abs}})$$

$$= 2.48(35) \times 10^{-4} \times (-2.83 + i1.22),$$

with $I(m_\mu^2/M_K^2, m_{\pi\pi}^2/M_K^2) = I_{\text{disp}} + iI_{\text{abs}}$, where a two-loop function $I(a, b)$ from the $2\pi^+2\gamma$ intermediate state is given in Refs. [10, 36], $B(K_S \to \gamma\gamma)_{\text{exp}} = 2.63(17) \times 10^{-6}$ [20] and the pion one-loop function $H(0) = 0.331 + i0.583$ [10] are used. Since this evaluation includes a 17% enhancement of the amplitude by a final-state interaction of the pions and it is reasonable for on-shell but not off-shell photon emission, a 30% uncertainty to the branching ratio is taken [11].

It is found that the interference affects the branching ratio at $O(60\%)$ and the unknown sign of $A_{L\gamma\gamma}^\mu$ can be uncovered if $D = O(1)$ can be used. Note that the error of $A_{S\gamma\gamma}^\mu$ dominates the uncertainties of all lines. Since the dispersive treatment [37] will sharpen $A_{S\gamma\gamma}^\mu$, the interference and $B(K_S \to \mu^+\mu^-)_{\text{SM}}$ will, hence, be transparent in these figures. We also comment on the difference between two effective branching ratios with different dilution factors $D$ and $D'$, $B(K_S \to \mu^+\mu^-)_{\text{eff}}(D) - B(K_S \to \mu^+\mu^-)_{\text{eff}}(D') \propto (D - D')$, where $D > 0$ and $D' < 0$.
for $K^0$ and $\bar{K}^0$ tagging, respectively. This measurement does not receive a large uncertainty from $A_{\gamma\gamma}^{0}$, so that one can more clearly determine the sign of $A(K_L \to \gamma\gamma)$. Note that because $\sigma(pp \to K^0 X) \simeq \sigma(pp \to K^0 X)$, $D$ would be 0 as a standard of the LHCb experiment. We propose two methods for generating $K^0-\bar{K}^0$ asymmetry in the neutral kaon signals. The first one is the tagging of a charged kaon which accompanies the neutral kaon beam. An $O(30\%)$ of prompt $K^0$ accompanies $K^-$ through $pp \to K^0 K^- X$ [35]. Such a charged kaon track with a $K \to \mu^+\mu^-$ signal can be tagged by using the RICH detectors. This charged kaon tagging has been utilized to tag $B^0$ in the LHCb experiment [38]. A similar tagging would be possible for $\Lambda^0$ through $pp \to K^0\Lambda^0 X$ with $\Lambda^0 \to p\pi^-$. Another proposal is a charged-pion tagging using $pp \to K^+ X \to K^0\pi^+ X$. A similar charged-pion tagging for $D^0 (D^{*+} \to D^0\pi^+)$ has been achieved in the LHCb experiment [40].

**PROBING NEW PHYSICS**

We now investigate the influence of new physics on the interference. In general new physics, only three operators can contribute to $K \to \mu^+\mu^-$. Then, the interference term in Eq. (10) can be extended to

$$\sum_{\text{spin}} A(K_1 \to \mu^+\mu^-)^* A(K_2 \to \mu^+\mu^-)$$

$$= \frac{8G_F^2 M_W^4 F_K^2 M_K^2 m_L^2}{\pi^4} \left[ 1 - \frac{4m_{\mu}^2}{M_K} \right] \left\{ A_{\text{eff}}^{\mu\mu} \right\}^{*} + \frac{M_K^2}{M_W^2} \text{Re} \, \bar{y}_S \right\} i \frac{M_K^2}{M_W^2} \text{Im} \, \bar{y}_S$$

$$+ \frac{2\pi \sin^2 \theta_W (\text{Im} \, \lambda_i \, y'_{\gamma A} + \text{Im} \, \bar{y}'_{\gamma A}) - i \frac{M_W^2}{M_W^2} \text{Im} \, \bar{y}_P}$$

$$\times \left\{ -2 \pi \sin^2 \theta_W \left( \text{Re} \, \lambda_i \, y'_{\gamma A} + \text{Re} \, \lambda_i \, y_{\gamma e} + \text{Re} \, \bar{y}'_{\gamma A} \right) \right.$$}

$$+ A_{\text{eff}}^{\mu\mu} + \frac{M_K^2}{M_W^2} \text{Re} \, \bar{y}_P \left\}, \right.$$  

where the Wilson coefficients are defined in [31]

$$\mathcal{H}_{\text{eff}}^{[A_{\text{eff}}]} = \frac{G_F^2 m_{\mu}^2}{\pi^2} \left\{ \bar{y}'_S (\bar{\tau}_\gamma \bar{\gamma}_d) (\bar{\mu}_d) + \bar{y}'_P (\bar{\tau}_\gamma \bar{\gamma}_d) (\bar{\mu}_d\bar{\gamma}_d) \right\}$$

$$+ \frac{G_F^2 \alpha}{\sqrt{2}} (\lambda_i \, y'_{\gamma A} + \bar{y}'_{\gamma A}) (\bar{\tau}_\gamma \bar{\gamma}_d) (\bar{\mu}_d\bar{\gamma}_d) + \text{H.c.} \right.$$  

Here, new physics contributions are represented by $\bar{y}'_S$, and $\alpha = \alpha_{\text{eff}}(M_Z) = 1/127.95$ [20]. We find that the interference in Eq. (14) is still a genuine direct $CP$-violating contribution. The new physics contributions ($\bar{y}'_S$, $\bar{y}'_P$, and $\bar{y}'_{\gamma A}$) to $\Gamma(K_{1,2} \to \mu^+\mu^-)$ are given in Ref. [31].

The following is a specific example of new physics: we focus on a modified $Z$-coupling model [41–45], which can easily explain a $2.8\sigma - 2.9\sigma$ discrepancy in $\epsilon_K/\epsilon_K$ between the measured values and the predicted one at next-to-leading order [7–9]. In this model, after the electroweak symmetry breaking, the following flavor-changing $Z$ interactions emerge:

$$\mathcal{H}_{\text{eff}}^{[A_{\text{eff}}]} = -\Delta_{L}^{NP} \bar{\tau}_\mu \bar{\gamma}_L d Z^\mu + (L \leftrightarrow R) + \text{H.c.} \right.$$  

In our analysis, we assume that the new physics is only left handed and that it is pure imaginary, for simplicity: $\Delta_{L}^{NP} = 0$. According to Ref. [44], the $\epsilon_K/\epsilon_K$ discrepancy is explained at the $1\sigma$ level by the range of $-1.05 \times 10^{-6} < \text{Im} \, \Delta_{L}^{NP} < -0.50 \times 10^{-6}$ without conflict with $\epsilon_K$ and $B(K_L \to \mu^+\mu^-)$. This range corresponds to

$$0.86 \times 10^{-4} < \text{Im} \, \bar{y}'_{\gamma A} < 1.82 \times 10^{-4}, \quad \bar{y}'_S = \bar{y}'_P = 0.$$  

Green bands in Fig. 2 show that the effective branching ratio into $\mu^+\mu^-$ in Eq. (12), which can explain the $\epsilon_K/\epsilon_K$ discrepancy at $1\sigma$. It is observed that the interference vanishes or flips the sign compared to the SM predictions. This is because the interference is proportional to the direct $CP$ violation ($\text{Im} \, \lambda_i \, y'_{\gamma A} + \text{Im} \, \bar{y}'_{\gamma A}$) and $\text{Im} \, \lambda_i \, y'_{\gamma A} = -0.92 \times 10^{-4}$.

The other new physics scenario that can explain the $\epsilon_K/\epsilon_K$ discrepancy [46] will be presented in a forthcoming article [47].
**DISCUSSION AND CONCLUSIONS**

In this Letter, we have studied the interference between $K_L$ and $K_S$ in $K \to \mu^+\mu^-$ within the SM and the modified $Z$-coupling model, which could be probed by the future upgrade of the LHCb experiment. We have pointed out that the interference is a genuine direct CP-violation effect, so that one can investigate direct CP violation by precise measurement of $K \to \mu^+\mu^-$. It is found that within the SM the interference can amplify the effective branching ratio of $K_S \to \mu^+\mu^-$ in Eq. (12) by $\mathcal{O}(60\%)$ by determining the unknown sign of $\mathcal{A}(K_L \to \gamma\gamma)$, which can much reduce the theoretical uncertainty of $B(K_L \to \mu^+\mu^-)$. It is also shown that in the modified $Z$-coupling model, accounting for the $\epsilon_K'/\epsilon_K$ anomaly, the interference is predicted to vanish or flip the sign.

Such an investigation of the direct CP violation of kaon decay is important for, of course, $\epsilon_K'/\epsilon_K$ tension and also as a cross-check of the KOTO experiment, which is probing a CP-violating $K_L \to \pi^0\nu\pi$ decay and will reach SM sensitivity in 2021 [5, 48].

A similar study would be possible for $K_S \to \pi^+\pi^-\pi^0$ using the interference in the LHCb experiment. Although there are significant background events from $K_L \to \pi^+\pi^-\pi^0$, the Dalitz analysis of the momenta of the three pions can cut the background [28, 49].

**ACKNOWLEDGMENTS**

We would like to thank Diego Martinez Santos for valuable comments about the LHCb experiment and Ulrich Nierste for reading the manuscript. T. K. is also grateful to Yuto Minami for fruitful discussions. G. D. was supported in part by MIUR under Project No. 2015P5SBHT (PRIN 2015) and by the INFN research initiative ENP.
