Abstract: Considering nonlinear variation of working fluid’s specific heat with its temperature, finite-time thermodynamic theory is applied to analyze and optimize the characteristics of an irreversible Atkinson cycle. Through numerical calculations, performance relationships between cycle dimensionless power density versus compression ratio and dimensionless power density versus thermal efficiency are obtained, respectively. When the design parameters take certain specific values, the performance differences of reversible, endoreversible and irreversible Atkinson cycles are compared. The maximum specific volume ratio, maximum pressure ratio, and thermal efficiency under the conditions of the maximum power output and maximum power density are compared. Based on NSGA-II, the single-, bi-, tri-, and quadru-objective optimizations are performed when the compression ratio is used as the optimization variable, and the cycle dimensionless power output, thermal efficiency, dimensionless ecological function, and dimensionless power density are used as the optimization objectives. The deviation indexes are obtained based on LINMAP, TOPSIS, and Shannon entropy solutions under different combinations of optimization objectives. By comparing the deviation indexes of bi-, tri- and quadru-objective optimization and the deviation indexes of single-objective optimizations based on maximum power output, maximum thermal efficiency, maximum ecological function and maximum power density, it is found that the deviation indexes of multi-objective optimization are smaller, and the solution of multi-objective optimization is desirable. The comparison results show that when the LINMAP solution is optimized with the dimensionless power output, thermal efficiency, and dimensionless power density as the objective functions, the deviation index is 0.1247, and this optimization objective combination is the most ideal.

Keywords: irreversible Atkinson cycle; nonlinear variable specific heat; NSGA-II; multi-objective optimization; finite time thermodynamics

1. Introduction

More and more thermodynamic research have focused on the optimal performance of given thermodynamic process and the optimal configuration of a thermodynamic process with a given target extremum, which is defined as finite-time thermodynamics (FTT) [1–4]. The applications of FTT include many aspects, and the two major aspects are optimal configurations [5–21] and optimal performances [22–53] studies.

Many scholars have carried out a lot of research on the performance optimizations of the internal combustion engine cycles by using FTT theory; especially see the review article by Ge et al. [54]. For the Atkinson cycle (AC), when the working fluid’s (WF’s) specific heats (SHs) are constants [55–62], linear [63–69], and nonlinear [70–76] variable with its temperature, many scholars have analyzed and investigated its performance characteristics (PC) by taking into account the different cycle design parameters with different optimization objectives.
When the WF’s SHs are constants, Chen et al. [55] investigated the thermal efficiency ($\eta$) at maximum power density ($P_d$) criterion of a reversible AC without any losses. Rashidi and Hajipour [56] analyzed the influences of cycle intake air temperature, maximum temperature, and compression ratio on the power output ($P$) and $\eta$ PC of a reversible AC, and compared the optimal characteristics with those of Otto and Diesel cycles. Hou [57] derived the $P$ and $\eta$ PC of an endoreversible AC with heat transfer loss (HTL). References [58,59] derived the $P$ and $\eta$ PC of an irreversible AC by considering HTL and friction loss (FL). Zhao and Chen [60] derived the $P$ and $\eta$ PC of an irreversible AC with internal irreversibility loss (IIL) and HTL. Ust et al. [61] further considered IIL on the basis of reference [55], and studied the influences of IIL and cycle temperature ratio on the optimal $P_d$ PC of an irreversible AC. Shi et al. [62] further considered FL, HTL, and IIL on the basis of reference [55], and studied the influence of three losses on the $P_d$ PC of an irreversible AC. The analysis results revealed that the engine designed by maximum $P_d$ criterion is smaller in size and more efficient.

When the WF’s SHs are linear variable with its temperature, Al-sarkhi et al. [63] optimized $P_d$ PC of a reversible AC. Patodi and Maheshwar [64] compared the optimal performances under the maximum $P$, maximum $P_d$, and maximum effective criteria of a reversible AC. Ge et al. [65,66] derived the $P$ and $\eta$ PC of endoreversible [65] and irreversible [66] ACs. Lin and Hou [67] derived the $P$ and $\eta$ PC of an irreversible AC by taking into account the FL and HTL as the fuel energy percentage. Hajipour et al. [68] optimized the $P$ and $\eta$ PC of an irreversible AC by taking into account the FL, HTL, and IIL, and compared the results with those of Dual cycle and Dual-Atkinson cycle. Shi et al. [69] investigated the $P_d$ PC of an irreversible AC by taking into account the FL, HTL, and IIL and compared the cycle maximum specific volume ratio, $\eta$ and pressure ratio under the maximum $P$ and maximum $P_d$ criterions.

When the WF’s SHs are nonlinear variable with its temperature, Ge et al. [70] derived the $P$ and $\eta$ PC of an irreversible AC by taking into account the FL, HTL, and IIL. Ebrahimi [71] investigated the $P$ and $\eta$ PC of an irreversible AC by considering the influences of average piston speed, equivalent ratio, and cylinder wall temperature. Zhao et al. [72] analyzed the impacts of average piston velocity on the $P$, $\eta$, and $P_d$ PC of an irreversible AC. Gonca [73] compared the optimal performances of an irreversible AC under effective $P$ and effective $P_d$ criterions. Ebrahimi [74] analyzed the impact of volume ratio of the removal process on the $P$ and $\eta$ PC of an irreversible AC. Zhao and Xu [75] obtained the $P$, $\eta$, and $P_d$ PC of an irreversible AC by taking into account the influences of cycle parameters, geometric conditions, and operating variables, and compared the results with those of the Otto and Miller cycles. Ahmadi et al. [76] analyzed and optimized the $\eta$, ecological performance coefficient and ecological function ($E$) PC of an irreversible AC.

The research mentioned above have focused on single-objective optimization, but different optimization criteria may generate conflicts and lead to different results. Multi-objective optimization (MOO) has better coordination capabilities. NSGA-II is an effective algorithm for solving MOO problems, and it is widely used in the optimization of different cycles under different working conditions [77–95].

Ahmadi et al. [77,78] carried out MOO of solar powered engines [77] and solar disc-Stirling engines [78] by considering the $P$, $\eta$, and entropy generation rate as objective functions. Ahmadi et al. [79,80] also performed MOO of irreversible Stirling [79] and Ericsson [80] refrigerator cycles by considering the cooling load and coefficient of performance as optimization objectives. Ahmadi et al. [81] used $P_d$, $\eta$, and exergy loss density as objective functions to perform MOO of fuel cell-Braysson combined heat engine. Joker et al. [82] used $P$, $P_d$, $E$ density and exergy loss rate as objective functions to perform MOO of Brayton cycle hybrid system. Ghasemkhani et al. [83] performed MOO of endoreversible combined cycles under different heat exchangers. References [84–87] performed MOO on the performance of thermal and economic investment cost of organic Rankine cycle. References [88,89] performed MOO on the dimensionless $P$ ($P_d$), $\eta$, dimensionless $E$ ($E$), and dimensionless $P_d$ ($P_d$) of endoreversible [88] and irreversible [89] closed modified Brayton
cycles. References [90,91] carried out MOO of chemical reactor by considering the entropy generation and production rate as optimization objectives. Sadeghi et al. [92] performed MOO of solar hydrogen production plant by taking into account exergy efficiency and exergy cost of product as optimization objectives. References [93,94] carried out MOO on the total pumping power and entropy generation rate in ocean thermal energy conversion system [93] and surrogate models [94]. Shi et al. [64,95] optimized the AC [64] and Diesel cycle [95] PC under the condition of constant WF’s SHs, and obtained four-objective optimization results based on NSGA-II.

From the references mentioned above, there is no report about the $P_d$ performance of an irreversible AC with nonlinear variable WF’s SHs with its temperature, and MOO for AC is also rarely presented. Based on the model established in references [62,70], this paper further analyzes the maximum $P_d$ PC of an irreversible AC under the condition of nonlinear variable WF’s SHs with its temperature and compare the results with those obtained under the condition of the maximum $P$. Based on NSGA-II, the single-, bi-, tri-, and quadru-objective optimization results will be obtained when the compression ratio is used as the optimization variable and the $P$, $\eta$, $E$, and $P_d$ are used as the objective functions. Three decision-making methods are selected to analyze the optimization results and the best choices under different conditions are obtained. Compared with reference [62], a further step made in this paper is to perform single-, bi-, tri-, and quadru-objective optimization of different optimization objective combinations for an irreversible AC when the WF’s SHs are nonlinear variable with its temperature.

2. Cycle Model and Performance Parameters

Figure 1 shows the $T−s$ diagram (a) [62] and $p−v$ diagram (b) of the irreversible AC. An irreversible AC contains an adiabatic compression process 1 → 2, an isometric process 2 → 3, an adiabatic expansion process 3 → 4, and an isobaric process 4 → 1. The processes 1 → 2 and 3 → 4 are reversible processes without considering the IIL.

![Figure 1](image-url)

**Figure 1.** (a) $T−s$ representation of Atkinson cycle [62]. (b) $p−v$ representation of Atkinson cycle.

In the early research [62], the WF’s SHs were assumed to be constants, but in the actual cycle, accompanying with the combustion reaction, the nature and composition of WF will change. For this reason, the variable SH model can be used to obtain more accurate results. When the cycle-working-temperature range is 300 K – 3500 K, the nonlinear variable SH model is defined as [85]

\[
C_p = 7.2674 \times 10^{-10} T^2 + 4.2166 \times 10^{-6} T^{1.5} - 1.23134 \times 10^{-5} T + 9.1698 \times 10^{-4} T^{0.5} \\
+ 38.5787 - 4.3848 \times 10^5 T^{-1.5} + 8.8827 \times 10^6 T^{-2} - 6.4148 \times 10^8 T^{-3}
\]  

(1)

According to the relationship between constant pressure SH and constant volume SH, one has

\[
C_v = C_p - R
\]  

(2)
Then, the constant volume SH of the cycle is

\[ C_v = C_p - R = 7.2674 \times 10^{-10}T^2 + 4.2166 \times 10^{-6}T^{1.5} - 1.23134 \times 10^{-5}T + 9.1698 \times 10^{-4}T^{0.5} + 30.2642 - 4.3848 \times 10^5T^{-1.5} + 8.8827 \times 10^6T^{-2} - 6.4148 \times 10^8T^{-3} \] (3)

where \( R = 8.3145 \text{ J/(mol·K)} \) is the WF’s gas constant. The heat flux rate supplied to the AC is

\[
U = Q_{in} = m \int_{T_1}^{T_2} C_p dT = m \int_{T_1}^{T_2} (7.2674 \times 10^{-10}T^2 + 4.2166 \times 10^{-6}T^{1.5} - 1.23134 \times 10^{-5}T + 9.1698 \\
\times 10^{-4}T^{0.5} + 30.2642 - 4.3848 \times 10^5T^{-1.5} + 8.8827 \times 10^6T^{-2} - 6.4148 \times 10^8T^{-3}) dT
\]

\[ = m[2.422 \times 10^{-10}T^3 + 1.6866 \times 10^{-6}T^{2.5} - 6.1567 \times 10^{-6}T^2 + 6.1132 \times 10^{-4}T^{1.5} \\
+ 30.2642T + 8.7696 \times 10^5T^{-0.5} - 8.8827 \times 10^6T^{-1} + 3.2074 \times 10^8T^{-2}]_{T_2}^{T_3}
\] (4)

where \( m \) is the molar flow rate of the WF.

The heat flux rate transferred to the environment is

\[
Q_{out} = -m \int_{T_1}^{T_2} C_p dT = m \int_{T_1}^{T_2} C_p dT
\]

\[ = m[2.422 \times 10^{-10}T^3 + 1.6866 \times 10^{-6}T^{2.5} - 3.0783 \times 10^{-6}T^2 + 6.1132 \times 10^{-4}T^{1.5} \\
+ 38.5787T + 8.7696 \times 10^5T^{-0.5} - 8.8827 \times 10^6T^{-1} + 3.2074 \times 10^8T^{-2}]_{T_1}^{T_3}
\] (5)

For the two irreversible adiabatic processes \( 1 \rightarrow 2 \) and \( 3 \rightarrow 4 \), the IIL is defined as the irreversible compression and expansion efficiencies [62,70]

\[
\eta_c = \frac{(T_{2s} - T_1)}{(T_2 - T_1)}
\] (6)

\[
\eta_e = \frac{(T_4 - T_3)}{(T_{4s} - T_3)}
\] (7)

According to reference [70], the adiabatic process can be decomposed into numerous infinitely small processes. It is approximately considered that each infinitely small process has a constant adiabatic index. When the temperature of the WF changes \( dT \) and the specific volume changes \( dV \), one has

\[ TV^{k-1} = (V + dV)^{k-1}(T + dT) \] (8)

Changing Equation (8) one can obtain:

\[ C_v \ln(T_i/T_j) = -R \ln(V_i/V_j) \] (9)

where the temperature in \( C_v \) is the logarithmic average temperature between states \( i \) and \( j \), and \( T = (T_i - T_j)/\ln(T_i/T_j) \).

The cycle compression ratio \( \gamma \) and maximum temperature ratio \( \tau \) are defined as

\[
\gamma = V_1/V_2
\] (10)

\[
\tau = T_3/T_1
\] (11)

Therefore, for the two adiabatic processes \( 1 \rightarrow 2 \) and \( 3 \rightarrow 4 \) of an irreversible AC with WF’s SHs as nonlinear variable with its temperature, one has

\[ C_v \ln(T_{2s}/T_1) = R \ln \gamma \] (12)

\[ C_v \ln(T_{4s}/T_3) - R \ln(T_1/T_{4s}) = -R \ln \gamma \] (13)

According to the reference [62], the HTL rate and the power loss due to FL are expressed as

\[ \dot{Q}_{\text{leak}} = B(T_2 + T_3 - 2T_0) \] (14)
where $b = \mu x_2^2/\Delta t_{12})^2$, the heat transfer coefficient is expressed as $B$, the ambient temperature is expressed as $T_0$, the work consumed by friction loss is expressed as $W_{\mu}$, the friction coefficient is expressed as $\mu$, the piston position at the minimum volume is expressed as $x_2$, and the power stroke time is expressed as $\Delta t_{12}$.

The $P$ and $\eta$ of the AC are, respectively

$$P = Q_{in} - Q_{out} - P_{\mu}$$
$$= \dot{m}[2.422 \times 10^{-10}(T_1^2 + T_3^2 - T_2^2 - T_4^2) + 1.6866 \times 10^{-6}(T_1^{2.5} + T_3^{2.5} - T_2^{2.5}) - 6.1567$$
$$\times 10^{-6}(T_1^{T_1} + T_3^{T_1} - T_2^{T_1} - T_4^{T_1}) + 6.1132 \times 10^{-4}(T_1^{T_4} + T_3^{T_4} - T_2^{T_4} - T_4^{T_1}) + 30.2642(T_3 - T_2)$$
$$- 38.578(T_4 - T_1) + 8.7696 \times 10^5(T_1^{T_1} + T_2^{T_1} - T_3^{T_1} - T_4^{T_1} - 8.8827 \times 10^6(T_1^{T_1} + T_3^{T_1}$$
$$- T_2^{T_1} - T_4^{T_1} + 3.2074 \times 10^9(T_1^{T_1} - T_3^{T_1} - T_2^{T_1} - T_4^{T_1})) - b(\gamma - 1)^2$$

$$\eta = P/(Q_{in} + Q_{out})$$
$$= \dot{m}[2.422 \times 10^{-10}(T_1^2 + T_3^2 - T_2^2 - T_4^2) + 1.6866 \times 10^{-6}(T_1^{2.5} + T_3^{2.5} - T_2^{2.5}) - 6.1567$$
$$\times 10^{-6}(T_1^{T_1} + T_3^{T_1} - T_2^{T_1} - T_4^{T_1}) + 6.1132 \times 10^{-4}(T_1^{T_4} + T_3^{T_4} - T_2^{T_4} - T_4^{T_1}) + 30.2642(T_3 - T_2)$$
$$- 38.578(T_4 - T_1) + 8.7696 \times 10^5(T_1^{T_1} + T_2^{T_1} - T_3^{T_1} - T_4^{T_1} - 8.8827 \times 10^6(T_1^{T_1} + T_3^{T_1}$$
$$- T_2^{T_1} - T_4^{T_1} + 3.2074 \times 10^9(T_1^{T_1} - T_3^{T_1} - T_2^{T_1} - T_4^{T_1})) - b(\gamma - 1)^2$$

According to the definition of $P_d$ in references [55,62], one has

$$P_d = P/v_{max} = P/v_4$$

The entropy production rates resulting from the HTL, FL, and III are defined as

$$\sigma_\eta = B(T_2 + T_3 - 2T_0)/[1/T_0 - 2/(T_2 + T_3)]$$

$$\sigma_\mu = P_{\mu}/T_0 = b(\gamma - 1)^2/T_0$$

$$\sigma_{23\rightarrow 2} = \int_0^{T_2} CPD dT/T$$

$$\sigma_{45\rightarrow 4} = \int_0^{T_4} CPD dT/T$$

The entropy production rate produced by the exhaust stroke is

$$\sigma_{pq} = (\dot{m}/T_0)[2.422 \times 10^{-10}(T_2^2 - T_3^2) + 1.6866 \times 10^{-6}(T_2^{2.5} - T_3^{2.5}) - 6.1567 \times 10^{-6}(T_2^2 - T_4^2$$

$$+ 6.1132 \times 10^{-4}(T_1^{T_1} + T_3^{T_1} - T_2^{T_1} - T_4^{T_1}) + 8.7696 \times 10^5(T_1^{T_1} - T_1^{T_4}) - 8.8827$$

$$\times 10^6(T_2^{T_1} - T_2^{T_4}) + 3.2074 \times 10^9(T_2^{T_1} - T_2^{T_4})) - m[3.6337 \times 10^{-10}(T_1^2 - T_2^2)$$

$$+ 1.8339 \times 10^{-3}(T_1^{T_1} + T_1^{T_4}) + 38.578(T_4 - T_1) + 2.9232 \times 10^5(T_1^{T_1} - T_1^{T_4})$$

$$- 4.413 \times 10^9(T_2^{T_1} - T_2^{T_4}) + 2.1382 \times 10^8(T_1^{T_1} - T_1^{T_4})]$$

The total entropy production rate due to HTL, FL, III and exhaust process is
\[
\sigma = \sigma_0 + \sigma_\gamma + \sigma_{\gamma \rightarrow 2} + \sigma_{3 \rightarrow 4} + \sigma_{\eta 0} \\
= B_1 (T_2 + T_3 - 2T_0) [(1/T_3) - 2/(T_2 + T_0)] + b (\gamma - 1)^2 / T_0 + \hat{m} [3.6337 \times 10^{-10} (T_2^2 - T_{2s}^2 - T_{3s}^2 \\
+ T_1^2) + 2.8111 \times 10^{-6} (T_{2s}^{1.5} - T_{4s}^{1.5} + T_{3}^{1.5} + T_1^{1.5}) - 1.23134 \times 10^{-5} (T_2 - T_{2s} - T_{4s} + T_1) + 1.8339 \times 10^{-3} (T_2^0 - T_{2s}^0 - T_{4s}^0 + T_1^0) + 30.2642 \ln(T_2/T_{2s}) - 38.5787 \ln(T_{4s}/T_1) + 2.9232 \times 10^5 \\
(T_{2s}^{1.5} - T_{4s}^{1.5} - T_{3}^{1.5} + T_1^{1.5}) - 4.4413 \times 10^6 (T_2^2 - T_{2s}^2 - T_{4s}^2 + T_1^2) + 2.1382 \times 10^8 (T_{2s}^3 - T_{4s}^3 + T_1^3)] + \hat{m} [2.422 \times 10^{-10} (T_2^3 - T_1^3)] + 1.6866 \times 10^{-6} (T_{2s}^{2.5} - T_{3s}^{2.5} - T_{4s}^{2.5}) - 6.1567 \times 10^{-6} (T_{2s}^2 + T_{4s}^2 - 2T_1^2) + 6.1132 \times 10^{-4} (T_{3s}^{1.5} + T_{4s}^{1.5} - T_{2s}^{1.5} - T_1^{1.5}) + 30.2642 (T_3 - T_2) \\
- 38.5787 (T_4 - 2T_1) + 8.7696 \times 10^5 (T_{2s}^{0.5} - T_{4s}^{0.5} - T_{2s}^{0.5} - T_{4s}^{0.5}) - 8.8827 \times 10^6 (T_3^3 - 2T_2^3 - T_1^3)] + 3.2074 \times 10^8 (T_4^3 - T_1^3) + 1.8339 \times 10^{-3} (T_{2s}^{1.5} - T_{4s}^{1.5} + T_1^{1.5}) - 4.4413 \times 10^6 (T_2^2 - T_{2s}^2 - T_{4s}^2 + T_1^2) + 2.1382 \times 10^8 (T_{2s}^3 - T_{4s}^3 + T_1^3)] \\
\]
\[
E = P - T_0 \sigma \\
= \hat{m} [2.422 \times 10^{-10} (T_3^3 + 2T_2^3 - 2T_1^3)] + 1.6866 \times 10^{-6} (T_{2s}^{2.5} + 2T_{2s}^{2.5} - T_2^{2.5} - 2T_{2s}^{2.5}) - 6.1567 \times 10^{-6} (T_{2s}^2 + T_{4s}^2 - 2T_1^2) + 6.1132 \times 10^{-4} (T_{3s}^{1.5} + 2T_{4s}^{1.5} - T_{3s}^{1.5} - T_{4s}^{1.5}) + 30.2642 (T_3 - T_2) \\
- 38.5787 (T_4 - 2T_1) + 8.7696 \times 10^5 (T_{2s}^{0.5} - T_{4s}^{0.5} - T_{2s}^{0.5} - T_{4s}^{0.5}) - 8.8827 \times 10^6 (T_3^3 - 2T_2^3 - T_1^3)] + 3.2074 \times 10^8 (T_4^3 - T_1^3) + 1.8339 \times 10^{-3} (T_{2s}^{1.5} - T_{4s}^{1.5} + T_1^{1.5}) - 4.4413 \times 10^6 (T_2^2 - T_{2s}^2 - T_{4s}^2 + T_1^2) + 2.1382 \times 10^8 (T_{2s}^3 - T_{4s}^3 + T_1^3)] - B_1 (T_2 + T_3 - 2T_0) [1 - 2T_0/(T_2 + T_3)] - 2b (\gamma - 1)^2 \\
\]

According to the treatment method in the references [55,62], the \(P, \eta, E, \) and \(P_d\) are defined as

\[
\overline{P} = P / \overline{P}_{\max} \\
\overline{P}_d = P_d / (P_d)_{\max} \\
\overline{E} = E / \overline{E}_{\max} 
\]

When the compression ratio \(\gamma\), the cycle initial temperature \(T_1\), and the maximum temperature ratio \(\tau\) are given, the numerical solutions of temperatures at each state point and cycle performances can be obtained.

3. Performance Optimization with the Maximum Power Density Criterion

According to reference [62], the values of the cycle parameters can be determined: \(\hat{m} = 1 \text{ mol/s}, T_0 = 300 \text{ K}, T_1 = 350 \text{ K}, B = 2.2 \text{ W/K}, \tau = 4.28 - 6.28, b = 20 \text{ W}.\)

Figures 2 and 3 show the effect of cycle maximum temperature ratio (\(\tau\)) on cycle dimensionless power density versus compression ratio (\(P_d - \gamma\)) and cycle dimensionless power density versus thermal efficiency (\(P_d - \eta\)), respectively. It can be noticed that there is an optimal compression ratio (\(\gamma_{P_d}\)) to make \(P_d\) reach the maximum. As the \(\tau\) increases from 5.78 to 6.78, the \(\gamma_{P_d}\) increases from 8.3 to 9.0, and increases by about 8.434%. The \(\eta_{P_d}\) corresponding to the cycle maximum \(P_d\) increases from 0.4330 to 0.4579, and increases by 5.75%. It shows that under the maximum \(P_d\) criterion, the increases of the \(\gamma_{P_d}\) and \(\eta_{P_d}\) of the cycle are accompanied with the increase of the \(\tau\).
3. Performance Optimization with the Maximum Power Density Criterion

According to reference [62], the values of the cycle parameters can be determined: $\gamma$ increases from 5.78 to 6.78, the $\eta$ increases from 8.3 to 9.0, and increases by about 20.57%. It shows that under the maximum power density versus thermal efficiency ($P_d$ and $\gamma$), to make the cycle losses increase of the cycle are accompanied with the increase of the $\gamma$ and $\eta$.

$P_d$ and $\gamma$ of the cycle are accompanied with the increase of the $\eta$, and increases by about $0.4579$, and increases by $5.75\%$. It can be seen that under the maximum power density versus compression ratio ($\tau$), the $\gamma$ increases from 0 to $0.94$, the $\eta$ decreases from 0.94 to 0.94. The $\eta$ is an optimal compression ratio ($\eta_c = \eta_r = 0.94$).

The curves of Figures 2 and 3 show the effect of cycle maximum temperature ratio ($\tau$) on cycle parameters. In Figure 4, when only considering the FL, comparing curves 1 and 2, the FL increases from 0 to 20 W, the $\gamma_{P_d}$ decreases from 31.4 to 10.9 and decrease by 65.287%. When only considering the IIL, comparing curves 1 and 1', the IIL increases (from 1 to 0.94), the $\gamma_{P_d}$ will decrease from 31.4 to 18.5, and decrease by 41.083%. When considering both FL and IIL, comparing curves 1 and 2', the IIL increases (from 1 to 0.94) the FL increases from 0 to 20 W, the $\gamma_{P_d}$ will decrease from 31.4 to 9.1 and decrease by 71.019%. It can be seen that the decrease of the $\gamma_{P_d}$ of the cycle is accompanied with the increases of the cycle losses.

Figures 4 and 5 show the characteristic relationships of $P_d - \gamma$ and $P_d - \eta$ with different loss combinations. In Figure 4, when only considering the FL, comparing curves 1 and 2, the FL increases from 0 to 20 W, the $\gamma_{P_d}$ will decrease from 31.4 to 10.9 and decrease by 65.287%. When only considering the IIL, comparing curves 1 and 1', the IIL increases (from 1 to 0.94), the $\gamma_{P_d}$ will decrease from 31.4 to 18.5, and decrease by 41.083%. When considering both FL and IIL, comparing curves 1 and 2', the IIL increases (from 1 to 0.94) the FL increases from 0 to 20 W, the $\gamma_{P_d}$ will decrease from 31.4 to 9.1 and decrease by 71.019%. It can be seen that the decrease of the $\gamma_{P_d}$ of the cycle is accompanied with the increases of the cycle losses.
In Figure 5, when only considering the FL, comparing curves 1 and 2, the FL increases from 0 to 20 W, the $\eta_{T_d}$ will decrease from 0.7114 to 0.5611 and decrease by 21.13%. When only considering the HTL, comparing curves 1 and 3, the HTL increases from 0 to 2.2 W/K, the $\eta_{T_d}$ will decrease from 0.7114 to 0.6371 and decrease by 10.44%. When only considering the IIL, comparing curves 1 and 1’, the IIL increases (from 1 to 0.94), the $\eta_{T_d}$ will decrease from 0.7114 to 0.561 and decrease by 21.03%. When considering HTL and FL at the same time, comparing curves 1 and 4, the HTL increases from 0 to 2.2 W/K and the FL increases from 0 to 20 W, the $\eta_{T_d}$ will decrease from 0.7114 to 0.5618 and decrease by 37.32%. It can be seen that the decrease of the pressure ratio under the maximum $\gamma$ criterion is bigger. Therefore, the engine designed based on the maximum $\gamma$ criterion is smaller in size and more efficient.
0.7114 to 0.4791 and decrease by 32.65%. When considering FL, HTL, and IIL at the same time, comparing curves 1 and 4', the FL increases from 0 to 20 W, the HTL increases from 0 to 2.2 W/K, and the IIL increases from 1 to 0.94, the $\eta_{Pd}$ will decrease from 0.7114 to 0.4459 and decrease by 37.32%. It can be seen that the decrease of the $\eta_{Pd}$ of the cycle is accompanied with the increases of the cycle losses.

Figures 6–8 show the compared results of the cycle $\eta$, maximum specific volume ratio, and pressure ratio under the maximum $P$ and maximum $P_d$ criterions when there are three losses. Comparing with the maximum $P$ criterion, the $\eta$ and maximum pressure ratio under the maximum $P_d$ criterion are higher, while the maximum specific volume ratio under the maximum $P_d$ criterion is smaller. Therefore, the engine designed based on the maximum $P_d$ criterion is smaller in size and more efficient.

4. Multi-Objective Optimization

In actual cycle, there is no point at which the $P$, $\eta$, $E$, and $P_d$ are optimized at the same time. Therefore, when solving the MOO problem, it is very important to take into account the trade-offs between the interests of different objectives, and obtain the Pareto optimal solution that simultaneously satisfies multiple different or even contradictory goals. The Pareto frontier is defined as the solution set of the optimization objectives. Figure 9 shows the algorithm diagram of NSGA-II [62]. When taking the compression ratio as the optimization variable and taking the $P$, $\eta$, $E$, and $P_d$ as the optimization objectives, the single-, bi-, tri-, and quadru-objective optimization results are obtained. The optimal solution is obtained by comparing the magnitude of the deviation indexes obtained by LINMAP, TOPSIS, and Shannon entropy solutions.

The optimization problems are solved with different optimization objective combinations, which forms different MOO problems. The one quadru-objective optimization problem is as follows:

$$\max \left\{ \frac{P_d(\gamma)}{\eta(\gamma)}, \frac{\eta(\gamma)}{E(\gamma)}, \frac{P(\gamma)}{\eta(\gamma)}, \frac{P_d(\gamma)}{E(\gamma)} \right\} \quad (29)$$

The four tri-objective optimization problems are as follows:

$$\max \left\{ \frac{P(\gamma)}{\eta(\gamma)}, \frac{\eta(\gamma)}{E(\gamma)}, \max \left\{ \frac{P_d(\gamma)}{\eta(\gamma)}, \frac{\eta(\gamma)}{E(\gamma)} \right\} \right\}, \max \left\{ \frac{P(\gamma)}{\eta(\gamma)}, \max \left\{ \frac{\eta(\gamma)}{E(\gamma)}, \max \left\{ \frac{E(\gamma)}{P_d(\gamma)} \right\} \right\} \right\} \quad (30)$$

The six bi-objective optimization problems are as follows:

$$\max \left\{ \frac{P(\gamma)}{\eta(\gamma)}, \max \left\{ \frac{\eta(\gamma)}{E(\gamma)}, \max \left\{ \frac{E(\gamma)}{P_d(\gamma)} \right\} \right\} \right\}, \max \left\{ \frac{P(\gamma)}{\eta(\gamma)}, \max \left\{ \frac{\eta(\gamma)}{E(\gamma)}, \max \left\{ \frac{E(\gamma)}{P_d(\gamma)} \right\} \right\} \right\} \quad (31)$$

Table 1 lists the results of the MOO based on LINMAP, TOPSIS, and Shannon entropy solutions under different combinations of optimization objectives, and lists the results of single-objective optimization corresponding to the maximum $P$, maximum $\eta$, maximum $E$, and maximum $P_d$, and the corresponding deviation index. Figures 10–20 show the Pareto frontiers of different combinations of single-, bi-, tri-, and quadru-objective optimizations. The diamond represents the corresponding points of Shannon entropy solution, and the
positive and negative triangles represent the corresponding points of LINMAP and TOPSIS solutions, respectively.

Figure 16. Bi-objective optimization on $\overline{P} - \overline{E}$.
Figure 16. Bi-objective optimization on $P_E - P_{dE}$.

Figure 17. Bi-objective optimization on $dP - P_{dP}$.

Figure 18. Bi-objective optimization on $\eta - \overline{E}$. 

Figure 19. Bi-objective optimization on $d\eta - \overline{E}$.
The deviation indexes of maximum $\bar{P}$, maximum $\eta$, maximum $\bar{E}$, and maximum $\bar{P}_d$ are 0.7326, 0.2752, 0.1260, and 0.5120, respectively. For the quadrur-objective optimization, Figure 10 shows the Pareto frontier for $\bar{P} - \eta - \bar{E} - \bar{P}_d$. It can be noticed that with the increase of $\eta$, the $\bar{P}$ and $\bar{P}_d$ increase, and the $\bar{E}$ first increases and then decreases. The deviation indexes (0.1250, 0.1250, 0.5266) obtained by the LINMAP, TOPSIS, and Shannon entropy solutions are smaller than those of single-objective optimization. It means that the results obtained by four-objective optimization are more perfect than single-objective optimization. In addition, when taking $\bar{P}$, $\eta$, $\bar{E}$, and $\bar{P}_d$ as the objective functions, the deviation indexes obtained by LINMAP and TOPSIS solutions are the same, and the optimization results are more desirable than those obtained by the Shannon entropy solution.
For tri-objective optimization, Figures 11–14 show the Pareto frontiers for \( P - \eta - E \), \( P - \eta - d \), \( P - E - d \), and \( \eta - E - d \). It can be noticed that with the increases of \( \eta \), the \( P \) and \( d \) increase, while the \( E \) first increases and then decreases. With the increase of \( P \), the \( P \) decreases, the \( \eta \) increases, and the \( E \) first increases and then decreases. The deviation indexes obtained by different decision-makings are smaller than those obtained by single-objective optimization, and which is the same as that obtained by quadru-objective optimization. When taking \( P, \eta \), and \( E \) as the objective functions, the deviation index obtained by the Shannon entropy solution is smaller. When taking \( P, \eta \), and \( d \) as the objective functions, the deviation index obtained by the LINMAP solution is smaller. When taking \( P, E \), and \( d \) as the objective functions, the LINMAP and TOPSIS solutions get the same deviation indexes, and the optimization results are more desirable than those obtained by the Shannon entropy solution. When taking \( \eta, E \) and \( d \) as the objective functions, the deviation index obtained by the TOPSIS solution is smaller and the result is better.

For bi-objective optimization, Figures 15–20 show the Pareto frontiers for \( P - \eta, P - E \), \( P - d, \eta - E \), \( \eta - d \), and \( E - d \). It can be noticed that the \( \eta \), \( E \), and \( d \) decrease with the increase of \( P \). The indexes obtained by different decision-makings are smaller than those obtained by single-objective optimization, and the conclusion is the same as that obtained by tri- and quadru-objective optimization. When taking \( P \) and \( \eta \) or taking \( P \) and \( \eta \) as the objective functions, the deviation index obtained by the LINMAP solution is smaller. When taking \( P \) and \( d \) or taking \( E \) and \( d \) as the objective functions, the deviation index obtained by the Shannon entropy solution is smaller. When taking \( P \) and \( d \) or taking \( E \) and \( d \) as the objective functions, the deviation index obtained by the TOPSIS solution is smaller and the result is better.

By comparing the deviation indexes obtained under various conditions, the results show that the solution obtained by MOO is more desirable, and the deviation indexes are smaller. In addition, when the LINMAP solution is optimized with \( P, \eta \), and \( d \) as the objective functions, the deviation index is 0.1247, the contradiction obtained is the smallest, and the result is the best. In practical applications, the optimal plan can be selected from the Pareto frontier, and the design can be optimized according to the actual requirements of the decision-maker.

5. Conclusions

Through FTT analysis, this paper performs the performance analyses of the irreversible AC under the maximum \( P_d \) criterion when the WF’s SHs are nonlinear variable with its temperature. The results of the \( \eta \), maximum specific volume ratio and pressure ratio obtained under the maximum \( P_d \) criterion are compared with those under the maximum \( P \) criterion. Based on NSGA-II, when the compression ratio is the optimization variable and the \( P, \eta, E \), and \( d \) are the optimization objectives, the single-, bi-, tri-, and quadru-objective optimization results are obtained. The optimal solution is obtained by comparing the deviation indexes of LINMAP, TOPSIS, and Shannon entropy solutions. It can be noticed that:

1. There is an \( \gamma_{T_d} \) to maximize the \( T_d \). With the cycle maximum temperature ratio increases, the \( \gamma_{T_d} \) and \( \eta_{T_d} \) corresponding to the \( T_d \) will increase. With the increases of HTL, FL, IIL, the \( \gamma_{T_d} \) and \( \eta_{T_d} \) corresponding to the cycle maximum \( P_d \) will decrease.
2. Under the maximum \( P_d \) criterion, the \( \eta \) will be higher and the size will be smaller.
3. Compared with single-objective optimization, MOO has less contradictions and conflicts. Comparing the results of single-, bi-, tri-, and quadru-objective optimization, when the LINMAP solution is optimized with \( P, \eta \), and \( d \) as the objective functions, the contradiction is smaller and the result is more perfect.

Nomenclature

- $B$: Heat transfer loss coefficient (W/K)
- $C_p$: Specific heat at constant pressure (J/(mol·K))
- $C_v$: Specific heat at constant volume (J/(mol·K))
- $E$: Ecological function (W)
- $k$: Adiabatic index (-)
- $m$: Molar flow rate (mol/s)
- $P$: Power output (W)
- $P_d$: Power density (W/m$^3$)
- $Q$: Heat transfer rate (W)
- $R$: Gas constant (-)
- $T$: Temperature (K)

Greek symbol

- $\gamma$: Compression ratio (-)
- $\eta$: Thermal efficiency (-)
- $\eta_c$: Irreversible compression efficiency (-)
- $\eta_e$: Irreversible expansion efficiency (-)
- $\mu$: Friction coefficient (kg/s)
- $\sigma$: Entropy generation rate (W/K)
- $\tau$: Cycle maximum temperature ratio (-)

Subscripts

- $in$: Input
- $max$: Maximum value
- $out$: Output
- $P_d$: Max power density condition
- $\eta$: Max thermal efficiency condition
- $\theta$: Environment
- $1, 2, s, 4s$: Cycle state points

Superscripts
