The Fourier Discrepancy Function

Gennaro Auricchio, Andrea Codegoni, Stefano Gualandi and Lorenzo Zambon

Abstract—In this paper, we propose the Fourier Discrepancy Function, a new discrepancy to compare discrete probability measures. We show that this discrepancy takes into account the geometry of the underlying space. We prove that the Fourier Discrepancy is convex, twice differentiable, and that its gradient has an explicit formula. We also provide a compelling statistical interpretation. Finally, we study the lower and upper tight bounds for the Fourier Discrepancy in terms of the Total Variation distance.

Index Terms—Fourier metrics, discrepancy, weak convergence, maximum likelihood, tight bounds

I. INTRODUCTION

Comparing probability measures is a crucial task in several applied fields, such as computer vision [1], [2], [3], [4], [5], [6], [7], supervised learning [8], [9], [10], [11], [12] and generative models [13], [14], [15]. However, using different metrics for a given task can lead to different results [13]. For this reason, it is of crucial importance to have a wide range of mathematical tools and understand their features. For instance, in [16], a class of divergence measures based on the Shannon entropy has been introduced and studied. A relevant topic in information theory has then become to give a comparison between different discrepancy functions, especially in terms of tight bounds. The problem of finding tight bounds has been introduced in [17]; since then, many works have improved the constants of several known inequalities [18], [19], [20]. These bounds have also been proved to be useful for source coding [21], [22], [23].

In this paper, we introduce the Fourier Discrepancy Function, a distance between discrete probability measures inspired by the 1, 2—Periodic Fourier-Based Metric [24]. Metrics based on the Fourier Transform have been introduced in [25] and used in several fields, such as kinetic theory [26], [27], statistics [28], and, more recently, generative models [14]. The Fourier Discrepancy inherits the ability to capture the geometry of the underlying space, which is an appealing property in several applications [29], [30], [31]. Moreover, it is easy to compute using the Fast Fourier Transform [32].

In Section II we recall the most commonly used discrepancy functions for discrete probability measures and the 1, 2—Periodic Fourier Based Metric [24]. Then, in Section III we introduce the Fourier Discrepancy. We prove that the squared Fourier Discrepancy is twice differentiable. Unlike the Wasserstein distance [33], [34], its gradient has an explicit formula. Moreover, we prove that the Fourier Discrepancy is convex, and we provide an interesting statistical interpretation. Finally, in Section IV we study the lower and upper tight bounds for the Fourier Discrepancy in terms of the Total Variation distance. We close our paper with an open conjecture on the value of the upper tight bound.

II. DISCREPANCY FUNCTIONS FOR PROBABILITY MEASURES

A. Commonly used discrepancy functions

In this subsection, we recall the main distances and divergences used to compare discrete probability measures in computational applied mathematics. Here $(X, d)$ denotes a discrete finite metric space, and $\mathcal{P}(X)$ denotes the set of all the probability measures over $X$. For a complete discussion, we refer to [35], [36].

- The Total Variation distance ($TV$) [35] is defined as

$$TV(\mu, \nu) := \frac{1}{2} \sum_{x \in X} |\mu_x - \nu_x|.$$  

- The Kullback-Leibler divergence ($KL$) [37] is defined as

$$KL(\nu||\mu) := \sum_{x \in X} \log\left(\frac{\nu_x}{\mu_x}\right) \nu_x,$$  

if $\nu_x = 0$ for every $x$ such that $\mu_x = 0$, and otherwise $KL(\nu||\mu) := +\infty$. We follow the convention $0 \cdot \log(0) = 0$.

- The Wasserstein distance ($W_1$) [36], [38] is defined as

$$W_1(\mu, \nu) := \min_{\pi \in \Pi(\mu, \nu)} \left\{ \sum_{(x, y) \in X \times X} |x - y| \pi_{x, y} \right\},$$  

where

$$\Pi(\mu, \nu) := \left\{ \pi \in \mathcal{P}(X \times X) \text{ s.t.} \right\} \sum_{y \in X} \pi_{x, y} = \mu_x, \sum_{x \in X} \pi_{x, y} = \nu_y \}.$$  

Intuitively, $\pi_{x, y}$ denotes the amount of mass that is moved from the point $x$ to the point $y$ to reshape the configuration $\mu$ into the configuration $\nu$. The cost of moving a unit of mass from $x$ to $y$ is given by $|x - y|$. The Wasserstein distance is then the minimum cost for performing the total reshape.

Although these three functions are commonly used to compare measures, their features, and thus their behaviours when applied to a given task, are different. Studying these features is crucial to choosing the right discrepancy to be used for the given task. For example, the Total Variation is robust against random noise when used as a loss function for classification tasks [39], the Kullback-Leibler divergence is closely related to likelihood maximisation [29], [10], while the Wasserstein distance performs well at capturing the geometry of the underlying space [31], [36], [38].
B. The 1, 2—Periodic Fourier-based Metric

In this subsection, we review the main notions about the Fourier Transform of discrete measures (DFT) and about Fourier Based Metrics [26, 24, 25]. For a complete discussion on the DFT, we refer to [40].

In what follows, we fix \( X = I_N \), where \( I_N \subset [0,1] \) is defined as
\[
I_N := \left\{ 0, \frac{1}{N}, \ldots, \frac{N-1}{N} \right\},
\]
for any given \( N \in \mathbb{N} \). A discrete measure \( \mu \) on \( I_N \) is then defined as
\[
\mu := \sum_{j=0}^{N-1} \mu_j \delta_{\frac{j}{N}},
\]
where the values \( \mu_j \) are non-negative real numbers such that \( \sum_{j=0}^{N-1} \mu_j = 1 \). Since any discrete measure supported on \( I_N \) is fully characterised by the \( N \)-tuples of positive values \((\mu_0, \ldots, \mu_{N-1})\), we refer to discrete measures and vectors interchangeably.

**Definition 1.** The Discrete Fourier Transform (DFT) of \( \mu \) is the \( N \)-dimensional vector \( \hat{\mu} := (\hat{\mu}_0, \ldots, \hat{\mu}_{N-1}) \) defined as
\[
\hat{\mu}_k := \sum_{j=0}^{N-1} \mu_j e^{-2\pi i \frac{k}{N} j}, \quad k \in \{0, \ldots, N-1\}.
\]

**Remark 1.** Since the complex exponential function \( k \rightarrow e^{-2\pi i \frac{k}{N}} \) is a \( N \)-periodic function for any integer \( j \), we set
\[
\hat{\mu}_k := \hat{\mu}_{\text{mod}N(k)},
\]
for any \( k \in \mathbb{Z} \), where \( \text{mod}N(k) \) is the \( N \)-modulo operation. In particular, \( \hat{\mu}_{-k} = \hat{\mu}_{N-k} \) for any \( k \in \{0, \ldots, N-1\} \).

**Remark 2.** The DFT of a discrete measure can be expressed as a linear map:
\[
(\hat{\mu}_0, \ldots, \hat{\mu}_{N-1}) = \Omega \cdot (\mu_0, \ldots, \mu_{N-1}),
\]
where \( \Omega \) is the \( N \times N \) matrix defined as
\[
\Omega := \begin{bmatrix}
\omega_{0,0} & \omega_{0,1} & \cdots & \omega_{0,N-1} \\
\omega_{1,0} & \omega_{1,1} & \cdots & \omega_{1,N-1} \\
\vdots & \vdots & \ddots & \vdots \\
\omega_{N-1,0} & \omega_{N-1,1} & \cdots & \omega_{N-1,N-1}
\end{bmatrix},
\]
and \( \omega_{k,j} := e^{-2\pi i \frac{k}{N} j} \). Since the matrix \( \Omega \) is invertible, the DFT is a bijective function.

We now introduce the 1, 2—Periodic Fourier-based Metric [24].

**Definition 2.** Let \( \mu \) and \( \nu \) be two discrete measures over \( I_N \). The 1, 2—Periodic Fourier-based Metric is defined as
\[
D_{KL}^1(\mu, \nu) := \int_{[0,1]} \left| \sum_{j=0}^{N-1} (\mu_j - \nu_j) e^{-2\pi i jk} \right|^2 \frac{dk}{|k|^2}.
\]

In [24], it is proved that the integral in (7) converges for any pair of probability measures \( \mu \) and \( \nu \), and that \( D_{KL}^1 \) is equivalent to \( W_1 \).

**III. THE FOURIER DISCREPANCY FUNCTION**

In this section, we introduce the Fourier Discrepancy function, inspired by (7).

We compare the Fourier Discrepancy Function with other discrepancies, and we show with an example its ability to take into account the geometry of the underlying space. Then, we prove that the Fourier Discrepancy Function is convex, and we provide the explicit formula for the gradient and the Hessian matrix of its corresponding loss function. Finally, we present a statistical model with Gaussian noise in the space of frequencies, in which the minimisation of the Fourier Discrepancy is equivalent to the maximisation of the likelihood.

**Remark 3.** Herein, we only consider one-dimensional discrete measures, but all the results may be extended to a multi-dimensional setting.

Moreover, for the sake of simplicity, we assume that \( N \) is an even number.

Since \( \hat{\mu}_k = \frac{\mu_{N-k}}{N} \), we have
\[
|\hat{\mu}_k - \hat{\nu}_k| = |\hat{\mu}_{N-k} - \hat{\nu}_{N-k}|,
\]
which means that the \( k \)-th discrete frequencies give us the same information of the \( (N-k) \)-th ones. Therefore, we only consider the first \( \frac{N}{2} - 1 \) frequencies and we take half of the \( \frac{N}{2} \)-th frequency. We then propose the following discrete version of the metric in (7).

**Definition 3.** We define the Fourier Discrepancy function
\[
\mathbb{F} : \mathcal{P}(I_N) \times \mathcal{P}(I_N) \rightarrow [0, +\infty)
\]
as
\[
\mathbb{F}^2(\mu, \nu) := \sum_{k=1}^{N/2} \frac{|\hat{\mu}_k - \hat{\nu}_k|^2}{|k|^2} + \frac{1}{2} \left| \frac{\hat{\mu}_{N/2} - \hat{\nu}_{N/2}}{N/2} \right|^2
\]
\[
= \sum_{k=1}^{N/2} \frac{|\hat{\mu}_k - \hat{\nu}_k|^2}{|k|^2} + \frac{|\hat{\mu}_{N/2} - \hat{\nu}_{N/2}|^2}{N^2/4}.
\]

**Remark 4.** The function \( \mathbb{F} \) is a distance on \( \mathcal{P}(I_N) \). Moreover, the following holds:
\[
\frac{1}{N} C_1 \cdot W_1 \leq \mathbb{F} \leq C_2 \cdot W_1,
\]
where \( C_1, C_2 \) are positive constants that do not depend from \( \mu \) and \( \nu \). This follows from the equivalence between the Fourier-based metric and the Wasserstein distance [24].

**Example 1.** Figure [7] shows the behaviours of different discrepancy functions when comparing Dirac’s delta distributions. We have omitted the KL, since it is always equal to \( +\infty \) whenever the supports of the two distributions are disjoint. We highlight how the Fourier discrepancy, similarly to the \( W_1 \), is able to take into account the geometry of the underlying space.

To conclude, we provide an upper bound for the Fourier Discrepancy with respect to the Total Variation and the Kullback-Leibler.

**Proposition 1.** For any pair of probability measures \( \mu \) and \( \nu \), we have that
\[
\mathbb{F}(\mu, \nu) \leq \frac{2}{\sqrt{0}} TV(\mu, \nu).
\]
In many applications, discrepancies are used to evaluate how different a given probability measure is from a target one. An established tool to perform this comparison is the loss function. For any given \( \nu \in \mathcal{P}(I_N) \), we define the Fourier Loss Function \( L_\nu : \mathcal{P}(I_N) \rightarrow [0, \infty) \) as
\[
L_\nu(\mu) := \mathbb{F}^2(\mu, \nu).
\]
We are able to explicitly express the gradient and the Hessian matrix of this function.

**Proposition 4.** For any probability measure \( \nu \), the function \( L_\nu \) is twice differentiable. Moreover, its gradient and Hessian matrix are expressed through the explicit formulae:
\[
\langle \nabla L_\nu \rangle_l(\mu) = \frac{\partial L_\nu}{\partial \mu_l}(\mu) = 2 \sum_{j=0}^{N-1} (\mu_j - \nu_j) \cdot \text{Re} \left( \hat{b}_{j-l} \right),
\]
and
\[
\langle H L_\nu \rangle_{h,l}(\mu) = \frac{\partial^2 L_\nu}{\partial \mu_h \partial \mu_l}(\mu) = 2 \text{Re} \left( \hat{b}_{h-l} \right),
\]
where \( \hat{b} \) is the Fourier Transform of the vector \( b \).

In particular, \( L_\nu \) is a convex function for any \( \nu \in \mathcal{P}(I_N) \).

**B. Statistical interpretation**

We now show how the minimisation of the Fourier Discrepancy is related to the maximum likelihood estimator in classification models with a random noise. This is a classic framework in machine learning, where we often assume the existence of an underlying probabilistic model that generates the data \([9], [42]\). This model is typically expressed as
\[
y_i = f(x_i; \theta) + \epsilon_i, \quad i = 1, \ldots, m,
\]
where \((x_1, y_1), \ldots, (x_m, y_m)\) are the data, \(\epsilon_1, \ldots, \epsilon_m\) are i.i.d. random noises, \(f\) is a function that specifies the model structure, and \(\theta\) is the parameter that has to be optimised.

Let us suppose that, for every \( i = 1, \ldots, m, \epsilon_i \sim \mathcal{CN}(0, \Sigma) \), where \(\mathcal{CN}(0, \Sigma)\) is the circularly-symmetric complex normal distribution with zero mean and covariance matrix \(\Sigma\), defined as \(\Sigma := \text{diag}(2\sigma^2 \beta)\), for some \(\sigma > 0\), and where \(\beta\) is given by
\[
\beta := \left( 0, 1^2, \ldots, \left| \frac{N}{2} - 1 \right|^2, \left| \frac{N^2}{2} - 1 \right|^2, \ldots, 1^2 \right).
\]
For a complete discussion on complex normal distributions, we refer to \([43]\).

The likelihood of the observations \((x, y) = (x_i, y_i)_{i=1,\ldots,m}\) is then given by
\[
\mathbb{P}(y|x, \theta) = \prod_{i=1}^{m} \mathbb{P}(y_i = f_i + \epsilon_i) = \prod_{i=1}^{m} \mathbb{P}(\hat{y}_i = \hat{f}_i + \hat{\epsilon}_i) = C \cdot \prod_{i=1}^{m} \exp \left[ - \frac{1}{2} (\hat{y}_i - \hat{f}_i)^H \Sigma^{-1} (\hat{y}_i - \hat{f}_i) \right]
= C \cdot \exp \left[ - \frac{1}{2\sigma^2} \sum_{i=1}^{m} \mathbb{F}^2(y_i, f_i) \right],
\]
provided that the mass of $y_i$ is the same as $f_i$, for every $i = 1, \ldots, m$. The vector $(\tilde{y}_i - \tilde{f}_i) \cdot H$ denotes the conjugate transpose of $(\tilde{y}_i - \tilde{f}_i)$ and $C$ is a positive constant that does not depend on the data.

By taking the logarithm in (18), we obtain the following result.

**Theorem 1.** Let us consider a model of the form (17), where $(x_1, y_1), \ldots, (x_m, y_m)$ are the data and $\epsilon_1, \ldots, \epsilon_m$ are distributed as described above. Then, the value of $\theta$ maximising the likelihood of the data is the one minimising the Fourier Discrepancy

$$\frac{1}{m} \sum_{i=1}^{m} L_{\delta_{n_i}}(f(x_i; \theta)).$$

Notice that the structure of the covariance matrix $\Sigma$ measures how the error on the $k^{th}$ frequency is weighted. As the variance grows, we are more willing to accept discrepancies between the real value of the frequency and the predicted one. In particular, for $k = 0$, we have a null variance Gaussian (i.e. a Dirac’s delta). Therefore the model does not admit any error on the null frequency: $\mu$ and $\nu$ must have the same mass.

**IV. Tight Bounds**

In this section, we study the tight bounds for the Fourier Discrepancy in terms of the Total Variation distance.

A first result is given in Proposition 1. However, what we aim to find are the lower and upper tight bounds, respectively $C_L(\theta)$ and $C_U(\theta)$, defined, for any given $\theta \in (0, 1)$, as

$$C_L(\theta) := \inf_{\mu, \nu : TV(\mu, \nu) = \theta} F(\mu, \nu),$$

$$C_U(\theta) := \sup_{\mu, \nu : TV(\mu, \nu) = \theta} F(\mu, \nu).$$

Due to the linearity of the DFT, we have that

$$F(\mu, \nu)^2 = \sum_{k=1}^{N} \frac{|(\mu - \nu)_k|^2}{|k|^2},$$

we then set $\Delta := \mu - \nu$ and express both $TV$ and $F$ as functions of $\Delta$, rather than $\mu$ and $\nu$.

We now introduce and study the space of null sum measures.

**Definition 4.** We say that a real measure $\Delta$ is a null sum measure if

$$\sum_{i=0}^{N-1} \Delta_i = 0.$$ 

We denote by $\Theta$ the set of all the null sum measures.

Given any pair of probability measures $\mu$ and $\nu$, their difference is a null sum measure. As the following result shows, up to a multiplicative constant, the converse is also true.

**Proposition 5.** Given any non-zero $\Delta \in \Theta$ and $\theta \in (0, 1)$, there exists $C > 0$ and a pair of probability measures $(\mu, \nu)$ such that

$$\mu - \nu = C \cdot \Delta \quad \text{and} \quad TV(\mu, \nu) = \theta.$$

**Proof.** Let $C := \frac{\theta}{TV(\Delta)}$ and $\Delta := C \cdot \Delta$, which are well-defined since $TV(\Delta) \neq 0$ for any non-zero $\Delta$.

Then, for the $1$-homogeneity of $TV$, we have that

$$TV(\Delta) = \frac{\theta}{TV(\Delta)} \cdot TV(\Delta) = \theta.$$

Let $\mu$ and $\nu$ be, respectively, the positive and negative part of $\Delta$. Therefore, $\Delta = \mu - \nu$ and $\mu_i, \nu_i \geq 0$ for any $i$.

We have that

$$2\theta = \sum_{i} |\Delta_i| = \sum_{i} \mu_i + \sum_{i} \nu_i,$$

and moreover, since $\Delta$ is a null sum measure:

$$0 = \sum_{i} \Delta_i = \sum_{i} \mu_i - \sum_{i} \nu_i.$$

From (21) and (22) follows easily that $\sum_{i} \mu_i = \sum_{i} \nu_i = \theta$. We now define

$$\mu := \mu + (1 - \theta)\delta_0, \quad \nu := \nu + (1 - \theta)\delta_0.$$

We have that $\mu$ is a probability measure since $\mu_i \geq 0$ for any $i$ and $\sum_{i} \mu_i = \sum_{i} \nu_i + (1 - \theta) = 1$. The same holds for $\nu$.

Moreover, $\mu - \nu = \Delta$, hence $TV(\mu, \nu) = TV(\Delta) = \theta.$

**Remark 6.** Thanks to Proposition 5 and for the $1$-homogeneity of $F$, we have that

$$C_L(\theta) = \inf_{\Delta \in \Theta : TV(\Delta) = \theta} F(\theta, TV(\Delta)) = \theta \cdot \inf_{\Delta \in \Theta : TV(\Delta) = \theta} \frac{F(\Delta)}{TV(\Delta)},$$

and, analogously,

$$C_U(\theta) = \theta \cdot \sup_{\Delta \in \Theta : TV(\Delta) = \theta} \frac{F(\Delta)}{TV(\Delta)}.$$

**A. Lower tight bound**

Let us define the complex vector $\omega_k \in \mathbb{C}^N$ as

$$\omega_k = \left( e^{i \frac{2\pi k}{N}}, e^{i \frac{2\pi k}{N}}, \ldots, e^{i \frac{2\pi k}{N}} \right).$$

Since $\{\omega_k\}_{k=0}^{N-1}$ is an orthogonal basis of $\mathbb{C}^N$ [40], for any $\Delta \in \Theta$ there exists a unique $N$-tuple of complex coefficients $(\lambda^{(k)})_k$ such that

$$\Delta = \sum_{k=0}^{N-1} \lambda^{(k)} \omega_k.$$

We define

$$\Xi := \{ \Delta \in \Theta : \sum_{k=0}^{N-1} |\lambda^{(k)}| = 1 \}.$$

From (23), and for the $1$-homogeneity of both $TV$ and $F$, we have that:
\[ C_L(\theta) = \theta \cdot \inf_{\Delta \in \Theta} \mathcal{F}\left( \frac{\Delta}{TV\left( \sum |\lambda(k)| \right)} \right) \sum |\lambda(k)|, \]
\[ = \theta \cdot \inf_{\Delta \in \Xi} \frac{\mathcal{F}(\Delta)}{TV(\Delta)}. \]  

Lemma 2. We have that
\[ \sup_{\Delta \in \Xi} TV(\Delta) = \frac{N}{2}, \tag{27} \]
and the supremum is attained at \( \Delta = \omega_N \). 

Proof. Since \(|(\omega_k)_j| = |e^{2\pi jk}| = 1\) for all \( j \) and \( k \), we have that \( TV(\omega_k) = \frac{N}{2} \). Then, for any \( \Delta \in \Theta \) such that \( \sum |\lambda(k)| = 1 \), we have
\[ TV(\Delta) = TV\left( \sum_{k=0}^{N-1} \lambda(k) \omega_k \right) = \frac{1}{2} \sum_{j=0}^{N-1} \sum_{k=0}^{N-1} |\lambda(k)(\omega_k)_j| \]
\[ \leq \frac{1}{2} \sum_{j=0}^{N-1} \sum_{k=0}^{N-1} |\lambda(k)(\omega_k)_j| = \frac{1}{2} \sum_{j=0}^{N-1} \sum_{k=0}^{N-1} |(\omega_k)_j| \]
\[ = \frac{N}{2} \sum_{k=0}^{N-1} |\lambda(k)| = \frac{N}{2}. \]
Finally, notice that \( \omega_N \in \Theta \) since \( (\omega_N)_j = e^{i\pi j} = (-1)^j \), therefore \( \omega_N \) is real and \( \sum_{j=0}^{N-1} (\omega_N)_j = 0 \). \( \Box \)

Lemma 3. For any \( \Delta \in \Theta \), the Fourier Discrepancy is given by
\[ \mathcal{F}^2(\Delta) = N^2 \left( \sum_{k=1}^{N} \frac{|\lambda(k)|^2}{k^2} + \frac{|\lambda(\omega_N)|^2}{|N|^2} \right). \tag{28} \]

Proof. For any \( j = 0, \ldots, N - 1 \), we have that the DFT of \( \omega_j \) is given by
\[ (\widehat{\omega_j})_k = \sum_{l=0}^{N-1} e^{-i\frac{2\pi}{N}lk}(\omega_j)_l = \sum_{l=0}^{N-1} e^{-i\frac{2\pi}{N}lk-j} = N\delta_{k-j}. \]
Hence, for the linearity of the DFT:
\[ \hat{\lambda}_k = \sum_{j=0}^{N-1} \lambda(j)(\omega_j)_k = N \sum_{j=0}^{N-1} \lambda(j)\delta_{k-j} = N \lambda(k). \]

Lemma 4. We have that
\[ \inf_{\Delta \in \Xi} \mathcal{F}(\Delta) = 1, \]
and the infimum is attained at \( \Delta = \omega_N \).

Proof. Let \( \Delta \in \Xi \). Then \( \lambda(0) = \sum \Delta_j = 0 \). Moreover, since \( \Delta \) is real, we have that \( \hat{\lambda}_k = \frac{\Delta_k}{N-k} \) for any \( k = 1, \ldots, N - 1 \), hence \( |\lambda(k)| = |\lambda(N-k)| \). If we define
\[ \gamma_j := \begin{cases} 2|\lambda(j)| & \text{for } j = 1, \ldots, N/2 - 1, \\ |\lambda(\omega_N)| & \text{for } j = N/2, \end{cases} \]
from (28) we obtain
\[ \mathcal{F}^2(\Delta) = \frac{N}{2} \sum_{k=1}^{N} \frac{\gamma_k^2}{k^2}, \]
while the constraint (25) is written as
\[ \sum_{j=1}^{N} \gamma_j = 1. \]
It is easy to see that the minimum is achieved when \( \gamma_N = 1 \) and \( \gamma_j = 0 \) for \( j = 1, \ldots, N/2 - 1 \). Therefore \( \Delta = \omega_N \in \Xi \), and \( \mathcal{F}(\Delta) = 1 \). \( \Box \)

Combining (26) with Lemma 2 and Lemma 4, we infer that the lower tight bound is attained at \( \Delta = [-1, 1, -1, 1, \ldots, 1] \). Thanks to Proposition 5, we can conclude with the following theorem.

Theorem 5. The lower tight bound \( C_L(\theta) \) is given by
\[ C_L(\theta) = \frac{2\theta}{N}, \tag{29} \]
and is attained at
\[ \mu = \frac{2\theta}{N} [1, 0, 1, 0, \ldots, 0] + (1 - \theta)\delta_0, \]
\[ \nu = \frac{2\theta}{N} [0, 1, 0, 1, \ldots, 1] + (1 - \theta)\delta_0. \]

B. Upper tight bound
First, we introduce a suitable class of null sum measures.

Definition 5. For any \( i, j \in \{0, \ldots, N - 1\} \), we define the measure \( \eta_{i,j} \) as
\[ \eta_{i,j} := \delta_i - \delta_j. \]

Theorem 6. Let \( \Delta \) be a null sum measure on \( \{0, \ldots, N - 1\} \). Then, we can express \( \Delta \) as \( \Delta = TV(\Delta) \cdot \Delta' \), where \( \Delta' \) is a convex combination of \( \{\eta_{i,j}\}_k \) such that, for any pair \( \eta_{i,k} \) and \( \eta_{i',j'} \), we have
\[ i_k \neq j_k, \tag{30} \]
for any \( k \neq k' \).

Proof. Let \( \Delta \) be a null sum measure. Without loss of generality, we can reorder the values of \( \Delta \) as follows:
\[ \Delta = (\alpha_1, \ldots, \alpha_r, -\beta_1, \ldots, -\beta_l, 0, \ldots, 0), \]
where \( r + l \leq N \), \( \alpha_1, \beta_1 > 0 \), \( \alpha_i \leq \alpha_{i+1}, \beta_j \leq \beta_{j+1} \), for any \( i \) and \( j \), and \( \sum \alpha_i = \sum \beta_j \).
Without loss of generality, we assume that
\[ \alpha_1 \leq \beta_1. \]
Hence, we can write
\[ \Delta = \alpha_1 \eta_{0,r} + \Delta^{(1)}, \]
where
\[ \Delta^{(1)} = (0, \alpha_2, \ldots, \alpha_r, -\beta_1, \ldots, -\beta_1, 0, \ldots, 0) \]
\[ \Rightarrow (0, \alpha_2, \ldots, \alpha_r, -\beta_1 - \alpha_1, -\beta_2, \ldots, -\beta_l, 0, \ldots, 0). \]
Next, we compare $c_2^{(1)}$ and $\beta_2^{(1)}$ and repeat the process until every entry vanishes. At the end, we find
\[
\Delta = \lambda_1 \eta_{0,r} + \cdots + \lambda_k \eta_{r-1,N-1} =: \sum_k \lambda_k \eta_{i_k,j_k}.
\] (31)

Notice that each $\eta_{i,j}$ in (31) is such that $i < r$ and $j \geq r$ by construction, which implies condition (30).

Since by hypothesis, for any $l = 0, \ldots, N - 1$, all the l-th entries $(\eta_{i_k,j_k})$ have the same sign, we can write
\[
|\Delta| = \left| \sum_k \lambda_k (\eta_{i_k,j_k})_l \right| = \sum_k \lambda_k |(\eta_{i_k,j_k})_l|.
\]

Therefore:
\[
TV(\Delta) = \frac{1}{2} \sum_l |\Delta_l| = \frac{1}{2} \sum_l \sum_k \lambda_k |(\eta_{i_k,j_k})_l|
= \frac{1}{2} \sum_k \sum_l \lambda_k |(\eta_{i_k,j_k})_l|
= \frac{1}{2} \sum_k \lambda_k \sum_l |(\eta_{i_k,j_k})_l| = \sum_k \lambda_k,
\]

since $\sum_l |(\eta_{i_k,j})_l| = 2$ for any $i, j$. To conclude, it suffices to set
\[
\Delta' := \frac{1}{TV(\Delta)} \Delta = \sum_k \lambda_k \eta_{i_k,j_k},
\]
where $\lambda_k := \frac{\lambda_k}{\sum_i \lambda_i} > 0$, and $\sum_k \lambda_k = 1$.

**Theorem 7.** There exist $i^*, j^* \in \{0, \ldots, N - 1\}$ such that, for any $\theta \in (0, 1]$:
\[
\theta \cdot \eta_{i^*,j^*} = \arg \max_{TV(\Delta) = \theta} F(\Delta).
\] (32)

**Proof.** First, let us define
\[
(i^*, j^*) := \arg \max_{i,j \in \{0, \ldots, N - 1\}} F(\eta_{i,j}),
\] (33)

which exists since the maximum is taken over a finite set. For any $\theta \in (0, 1]$ and any null sum measure $\Delta$ with $TV(\Delta) = \theta$, thanks to Theorem 6, we can write $\Delta = \theta \cdot \sum_k \lambda_k \eta_{i_k,j_k}$.

From the 1-homogeneity and the convexity of $F$, we obtain:
\[
F(\Delta) = F \left( \theta \cdot \sum_k \lambda_k \eta_{i_k,j_k} \right) = \theta \cdot F \left( \sum_k \lambda_k \eta_{i_k,j_k} \right)
\leq \theta \cdot \sum_k \lambda_k F(\eta_{i_k,j_k}) \leq \theta \cdot \sum_k \lambda_k F(\eta_{i^*,j^*})
= \theta \cdot F(\eta_{i^*,j^*}) = \theta \cdot F(\eta_{i^*,j^*}).
\]

As a straightforward consequence, we get the following result.

**Corollary 1.** The upper right bound $C_U(\theta)$ is given by
\[
C_U(\theta) = \theta \cdot F(\eta_{i^*,j^*}).
\] (34)

Corollary 1 allows to search for the upper tight bound over a finite set of points. By explicit computation of the Fourier Discrepancy (see Appendix B), we have that
\[
F^2(\eta_{j,l}) = \sum_{k=1}^{N-1} \frac{2 - 2 \cos \left( \frac{2\pi j - l}{N} k \right)}{k^2} + 2 - 2 \cos(\pi j - l).
\]

Notice that $F(\eta_{j,l})$ depends on $j$ and $l$ only through $d := |j - l|$. Hence, we can further restrict to measures of the form $\eta_{0,d}$, with $d \in \{1, \ldots, N - 1\}$. By studying the derivatives with respect to $d$, it is possible to show that $d^* = \frac{N}{2}$ is a local minimum for the function $g : [0, N] \to \mathbb{R}$, defined as:
\[
g(d) := \sum_{k=1}^{N-1} \frac{2 \cos \left( \frac{2\pi d}{k} \right)}{k^2} + \frac{\cos(\pi d)}{N^2}.
\] (35)

We close our paper with the following open conjecture.

**Conjecture 1.** $d^* = \frac{N}{2}$ is a global minimum for $g$.

If our conjecture was true, we would have
\[
C_U(\theta) = \theta \cdot \sqrt{\sum_{k=1}^{N-1} \frac{2 - 2(-1)^k}{k^2} + 2 - 2(-1)^\frac{N}{2}}.
\]

**ACKNOWLEDGMENT**

We are deeply indebted to Giuseppe Toscani for several stimulating discussions and valuable suggestions on the Fourier Based Metrics. The research was partially supported by the Italian Ministry of Education, University and Research (MIUR): Dipartimenti di Eccellenza Program (2018–2022) - Dept. of Mathematics “F. Casorati”, University of Pavia. The PhD scholarship of Andrea Codecioni is funded by Sea Vision S.r.l.

APPENDIX A
PROOF OF PROPOSITION[1]

Proof. Let us fix two probability measures \( \mu \) and \( \nu \) over \( I_N \). By definition, we have

\[
\mathbb{F}(\mu, \nu)^2 = \sum_{k=1}^{N^2} \frac{1}{k^2} \left| \sum_{j=0}^{N-1} (\mu_j - \nu_j) (e^{-2\pi i \frac{j}{k}}) \right|^2
\]

where inequality (36) follows from the fact that \( N^{-2} \leq \frac{1}{N^2} \). The proof is concluded by taking the square root on both sides.

APPENDIX B
COMPUTING \( \mathbb{F}(\eta_{l,j}) \)

Let us consider null sum measures of the form \( \eta_{l,j} \). We recall that \( \eta_{l,j} := \delta_l - \delta_j \). Since

\[
\hat{\eta}_{l,j} = \Omega \cdot \eta_{l,j},
\]

we have

\[
\hat{\eta}_{l,j} = \Theta_l - \Theta_j,
\]

where \( \Theta_k \) is the \( k \)-th column of the matrix \( \Omega \). By the definition of \( \Omega \) we have

\[
\Theta_l = \left( e^{i \frac{2\pi l}{N}}, e^{i \frac{2\pi l}{N}}, \ldots, e^{i \frac{2\pi l}{N} (N-1)} \right),
\]

therefore, the value \( \mathbb{F}(\eta_{l,j})^2 \) is then given by

\[
\mathbb{F}(\eta_{l,j})^2 = \sum_{k=1}^{N^2} \frac{1}{k^2} \left| (\Theta_l - \Theta_j)_{k} \right|^2 + \frac{|(\Theta_l - \Theta_j)_{k}|^2}{N^2}.
\]

Let us now compute explicitly \( |(\Theta_l - \Theta_j)_{k}|^2 \) for a given \( k \).

We have

\[
(\Theta_l - \Theta_j)_k = \cos \left( \frac{2\pi l}{N} k \right) - \cos \left( \frac{2\pi j}{N} k \right)
+ i \sin \left( \frac{2\pi l}{N} k \right) - i \sin \left( \frac{2\pi j}{N} k \right),
\]

therefore

\[
| (\Theta_l - \Theta_j)_{k} |^2 = \left( \cos \left( \frac{2\pi l}{N} k \right) - \cos \left( \frac{2\pi j}{N} k \right) \right)^2
+ \left( \sin \left( \frac{2\pi l}{N} k \right) - \sin \left( \frac{2\pi j}{N} k \right) \right)^2
= 2 - 2 \cos \left( \frac{2\pi l}{N} \right) \cos \left( \frac{2\pi j}{N} \right)
+ \sin \left( \frac{2\pi l}{N} \right) \sin \left( \frac{2\pi j}{N} \right)
= 2 - 2 \cos \left( \frac{2\pi (j - l)}{N} k \right),
\]

where the equality in (39) comes from the following trigonometric identity:

\[
\cos(\alpha - \beta) = \cos(\alpha) \cos(\beta) + \sin(\alpha) \sin(\beta).
\]

Therefore

\[
\mathbb{F}^2(\eta_{l,j}) = \sum_{k=1}^{N^2} \frac{2}{k^2} - 2 \cos \left( \frac{2\pi l}{N} \right) \cos \left( \frac{2\pi j}{N} \right)
+ 2 - 2 \cos \left( \frac{2\pi (j - l)}{N} \right).
\]
