Abstract. The potentials for a one dimensional Schrödinger equation that are displaced along the $x$ axis under second order Darboux transformations, called 2-SUSY invariant, are characterized in terms of a differential-difference equation. The solutions of the Schrödinger equation with such potentials are given analytically for any value of the energy. The method is illustrated by a two-soliton potential. It is proven that a particular case of the periodic Lamé-Ince potential is 2-SUSY invariant. Both Bloch solutions of the corresponding Schrödinger equation are found for any value of the energy. A simple analytic expression for a family of two-gap potentials is derived.

1. Introduction

Originally, it was noticed in the context of periodic potentials [1, 2] that transformed Hamiltonians under special Darboux transformations are displaced with respect to the initial potential by half a period. Later on, this effect was studied in more detail with respect to first order Darboux transformations (also called 1-SUSY transformations) [3, 4]. It was shown that the range of possible displacements produced by a Darboux transformation is not restricted to half a period, but can take on values in a set of (in general) complex values called “Darboux displacements” (or SUSY displacements). The potentials allowing such displacement are called translationally invariant under the Darboux transformation or, simply, 1-SUSY invariant. It was proven that a real-valued even potential function $V_{0}(x) = V_{0}(-x)$ is 1-SUSY invariant if and only if it is of the form $V_{0}(x) = 2\wp(x + \omega')$, where $\wp(x) = \wp(x, g_{2}, g_{3})$ is the standard Weierstrass elliptic function with real and imaginary half-periods $\omega$ and $\omega'$ and invariants $g_{2}, g_{3}$ [5] (including its degenerate forms such as $2x^{-2}, -2\cosh^{-2}x$, and $2\sinh^{-2}x$). This result really means that the family of 1-SUSY invariant potentials is rather sparse. Moreover, it was noticed in [3] that a simple displacement appears to be a “frustrated case” of the Darboux method. Nevertheless, this property has led to mathematically nontrivial results and to unexpected link between the theory of elliptic functions and supersymmetric quantum mechanics [3, 4]. From a physical point of view a very remarkable property of 1-SUSY invariant potentials is that the corresponding Bloch solutions can be found analytically for any value of the energy. If a linear combination of Bloch solutions is used as the transformation function for a simple SUSY transformation, it produces an exactly solvable potential with locally perturbed periodic structure. We believe these potentials could find applications in describing contact effects in crystals, or modelling crystals with embedded inclusions.

In this paper we continue the investigation of SUSY invariant potentials, but at the level of second order Darboux transformations. The aim of this work is to study what happens if a potential is assumed to be 2-SUSY invariant, i.e., a second Darboux transformation results only in a displacement $V_{0}(x) \rightarrow V_{2}(x) = V_{0}(x + d)$. From the very beginning it is clear that this condition is weaker than 1-SUSY invariance, since any 1-SUSY invariant potential is obviously also 2-SUSY invariant. Actually, as a preliminary result shows [4], the family of 2-SUSY invariant potentials is richer than that of 1-SUSY invariant ones; at least, it includes a class of 2-soliton potentials which are not 1-SUSY invariant. Indeed, as we show below, it is even much richer, since a simple Darboux transformation over such a potential gives another 2-SUSY invariant potential which cannot be reduced to a displaced copy of the initial one. Another remarkable property of a 2-SUSY invariant potential is that it allows for an analytic
representation of both linearly independent solutions of the corresponding Schrödinger equation at any value of the energy (not necessarily from the spectral set). Using this property we are also able to generate new exactly solvable potentials with locally distorted periodic structure, as illustrated below. Our results lead us to hypothesise that the general Lamé-Ince potential is invariant under an \( n \)th order Darboux transformation.

This paper is organized as follows. In the next Section we review several properties of Darboux transformations and 1-SUSY invariant potentials. In Section 3 we prove necessary and sufficient conditions for a potential \( V_0(x) \) to be 2-SUSY invariant and point out some simple implications of this property. Section 4 has purely illustrative character. Here we apply the results of the previous section to a well-studied family of 2-soliton potentials. Section 5 is devoted to an analysis of the \( n = 2 \) case of the Lamé-Ince potential \( V_0(x) = n(n+1)\psi(x+\omega') \). It should be mentioned that this remarkable potential has attracted much attention from mathematicians as well as physicists. Without going into further details we refer the interested reader to the excellent recent papers \[6\] where a vast literature is summarized. We believe that our general results applied to the \( n = 2 \) case establish new properties of this remarkable potential. In particular, we show that it is 2-SUSY invariant and give a simple analytic representation of its linearly independent Bloch solutions in terms of the Weierstrass functions. Further we give an explicit formula for 1-parameter family of two-gap (i.e. having only two finite forbidden and allowed bands) potentials. General properties of such potentials have been studied by algebraic-geometrical methods (see e.g. \[6, 7\]). The most striking of our developments is that we use only elementary means and the well-known properties of Weierstrass functions presented in \[5\].

2. Preliminaries

Darboux transformations (also known as SUSY-QM transformations) have become an important tool for dealing with spectral problems associated with the Schrödinger equation, especially in one spatial dimension. Though the basic procedure is quite simple, the method has attracted increasing attention from mathematicians and physicists for more than a century (see e.g. \[8, 9\]).

One begins with a Hamiltonian

\[
    h_0 = -\partial^2 + V_0(x), \quad \partial \equiv d/dx, \quad x \in \mathbb{R},
\] 

(2.1)
Second Order Darboux Displacements

(in appropriate units) whose eigenspace is two dimensional for any eigenvalue $a \in \mathbb{C}$:

$$h_0 u(a, x) = a u(a, x), \quad h_0 \tilde{u}(a, x) = a \tilde{u}(a, x). \quad (2.2)$$

As it is well-known, imposition of boundary, summability or Bloch type constraints selects “physical” solutions $\psi(E, x)$ and leads to physical interpretation of the eigenvalue $E$ as a spectral parameter:

$$h_0 \psi(E, x) = E \psi(E, x), \quad E \in \mathbb{R}. \quad (2.3)$$

If $u_1 \equiv u(a_1, x)$ is a real and nodeless solution of equation (2.2), then the 1-SUSY partner Hamiltonian

$$h_1 = -\partial^2 + V_1(x), \quad V_1(x) = V_0(x) - 2(\ln u_1)'' \quad (2.4)$$

(the prime denotes the derivative with respect to $x$) is isospectral with $h_0$. (For non-periodic $V_0(x)$ the spectrum of $h_1$ may change in one point, but we ignore this for the moment).

Furthermore, an intertwining operator $L$ obeying $L h_0 = h_1 L$ has the form

$$L = -\partial + (\log u_1)' \quad (2.5)$$

Thus, the eigenfunctions of $h_1$ for eigenvalue $a \neq a_1$ are $v(a, x) = L u(a, x), h_1 v(a, x) = a v(a, x)$. This procedure can be repeated by starting with $h_1$ to produce a second isospectral Hamiltonian $h_2 = -\partial^2 + V_2(x)$, etc. It can be shown that in this way, for fixed $u_1$ and $u_2 \equiv u(a_2, x)$, the transformed potential is expressed in terms of the Wronskian $W(x) \equiv W(u_1, u_2) = u_1 u_2' - u_1' u_2$ as

$$V_2(x) = V_0(x) - 2[\log W(x)]'' \quad (2.6)$$

For $a \neq a_1, a_2$ the eigenfunctions of $h_2$ are $v(a, x) = W(u_1, u_2, u) W^{-1}(u_1, u_2), h_2 v(a, x) = a v(a, x)$ where $u \equiv u(a, x)$. It is easy to see that $W(u_1, u, \tilde{u}_1, 2) \propto u_{2,1}$ so that for $a = a_1, a_2$, up to an inessential constant factor, this formula gives

$$v_{1,2} \equiv v_{1,2}(a_{1,2}, x) = u_{1,2} W^{-1}(u_1, u_2), \quad h_2 v_{1,2} = a_{1,2} v_{1,2}. \quad (2.7)$$

We note that this is a particular case of a much more general result for a chain of $N$ Darboux transformations [9]. Solutions of the initial Schrödinger equation $u_j \equiv u_j(a_j, x)$ are called transformation functions while their eigenvalues $a_j$ are known as factorization constants. We refer the reader to [9] for more details.

A particularly interesting case is where $V_0$ is periodic:

$$V_0(x + T) = V_0(x). \quad (2.8)$$
We recall that inside the eigenfunction space of each eigenvalue for such a Hamiltonian we can build up Bloch functions, i.e., two linearly independent solutions $u^\pm$ of $h_0 u^\pm = a u^\pm$ such that
\begin{equation}
    u^\pm(a, x + T) = [\beta(a)]^{\pm 1} u^\pm(a, x), \quad \beta(a) \in \mathbb{C}.
\end{equation}

When for $a = E$ one has $|\beta(E)| = 1$, the $E$-values belong to a spectral band and the corresponding ("physical") solutions are bounded, while for $|\beta(a)| \neq 1$ they are unbounded ("non-physical") and the values of $a$ lay in forbidden bands (see e.g. [10]). By using appropriate Bloch functions as transformation functions in the Darboux algorithm one can construct periodic partner Hamiltonians [11–4], [11]. A linear combination of Bloch functions leads to a perturbed periodic structure which is asymptotically periodic.

Let, for instance, the transformation functions be Bloch functions $u_1^+(x)$ and $u_2^-(x)$ with corresponding factors $\beta_{1,2} = \beta(a_{1,2})$ as defined in (2.9). Then, according to (2.7), Bloch solutions of the transformed equation corresponding to eigenvalues $a_1$ and $a_2$ are respectively
\begin{equation}
    v_1^- = \frac{u_2^-}{W(x)}, \quad v_2^+ = \frac{u_1^+}{W(x)}, \quad h_2 v_1^\pm = a_{1,2} v_1^\pm,
\end{equation}

where
\begin{equation}
    v_1^-(x + T) = \beta_1^{-1} v_1^-(x), \quad v_2^+(x + T) = \beta_2 v_2^+(x).
\end{equation}

If under a Darboux transformation we have
\begin{equation}
    V_1(x) = V_0(x + d)
\end{equation}
then $d$ is called a Darboux displacement and $V_0$ is said to be 1-SUSY invariant. The first cases of Darboux displacements were found for periodic potentials [11, 2]. Later it was proven [3] that an even function $V_0(x)$ allows for a first order Darboux displacement if and only if it satisfies the nonlinear differential-difference equation
\begin{equation}
    V_0(x) + V_0(x + d) - \frac{1}{2} \left( \frac{V''_0(x) + V''_0(x + d)}{V_0(x) - V_0(x + d)} \right)^2 = \text{const},
\end{equation}

which, up to a constant, is equivalent to the addition formula for the Weierstrass $\wp$ function. This result means that the family of even 1-SUSY invariant potentials is restricted to the $\wp$ function and its degenerate forms, such as one-soliton potentials. In the next Section we prove necessary and sufficient conditions for a potential $V_0$ to admit a displacement under a second order Darboux transformation. The potentials possessing this property will be called 2-SUSY invariant.
3. Second order Darboux displacements

Let, as before, \( u_1^+(x) \) and \( u_2^-(x) \) be two Bloch eigenfunctions of \( h_0 \) which are chosen as transformation functions for a 2-SUSY transformation. Although we concentrate on the case of periodic potentials \( V_0(x+T) = V_0(x) \), our results have a more general character, as will be mentioned below. Now we assume that the potential \( V_2 \), obtained according to (2.6), is displaced from the original one, i.e.,

\[
V_2(x) = V_0(x + d) .
\]  

(3.1)

Thus, the differential equations corresponding to \( h_0 \) and \( h_2 \) have exactly the same solutions, but shifted by the displacement \( d \). Hence, taking into account the property (2.11) we see that

\[
v_1^-(x - d) \propto u_1^- (x) , \quad v_2^+(x - d) \propto u_2^+ (x) .
\]  

(3.2)

From this and (2.10) it follows readily that

\[
W(x) = c_1 \frac{u_2^-(x)}{u_1^-(x + d)} = c_2 \frac{u_1^+(x)}{u_2^+(x + d)} ,
\]  

(3.3)

where \( c_{1,2} \) are constants. It is convenient to use the notation

\[
\tilde{x} = x + d , \quad \Phi(x) = 1/W(x) , \quad p(x) = -2[\ln \Phi(x)]' .
\]  

(3.4)

Therefore, \( p'(x) = V_0(x) - V_0(\tilde{x}) \) and from (3.3) it follows that

\[
u_1^-(\tilde{x}) = c \Phi(x) u_2^-(x) ,
\]  

(3.5)

where \( c \) is an inessential non-zero constant. After taking the second derivative of (3.3) and using (2.2), one obtains

\[
[V_0(\tilde{x}) - a_1] \Phi(x) u_2^-(x) = [V_0(x) - a_2] \Phi(x) u_2^-(x) + [u_2^-(x)]' \Phi'(x) .
\]  

(3.6)

Now, from (3.4) one has

\[
\Phi' = -\frac{p}{2} \Phi , \quad \Phi'' = -\frac{p'}{2} \Phi + \frac{p^2}{4} \Phi ,
\]  

(3.7)

and from (3.6) this yields

\[
[\ln u_2^-(x)]' = \frac{p'}{2p} + \frac{p}{4} + \frac{a_1 - a_2}{p} .
\]  

(3.8)

Similarly

\[
[\ln u_1^+(x)]' = \frac{p'}{2p} + \frac{p}{4} - \frac{a_1 - a_2}{p} ,
\]  

(3.9)
Second Order Darboux Displacements

\[ \left[ \ln u_2^+ (\bar{x}) \right]' = \frac{p'}{2p} - \frac{p}{4} - \frac{a_1 - a_2}{p} , \]

(3.10)

\[ \left[ \ln u_2^- (\bar{x}) \right]' = \frac{p'}{2p} - \frac{p}{4} + \frac{a_1 - a_2}{p} . \]

(3.11)

Remark 1 The formulas (3.8)–(3.11) illustrate one of the most remarkable properties of a 2-SUSY invariant potential. The four Bloch functions corresponding to the eigenvalues \( a_1 \) and \( a_2 \) producing a displacement are expressible only in terms of the potential difference \( p'(x) = V_0(x) - V_0(x + d) \) (a known function) and its primitive (also known from Eq. (3.19) below).

Later on for a particular case of the Weierstrass potential we will integrate these equations to get analytic expressions for the solutions of the Schrödinger equation.

We turn next to finding necessary and sufficient conditions for \( V_0(x) \) to admit a displacement under a second order Darboux transformation (shortly second order Darboux displacement).

Proposition 1 The Hamiltonian \( h_0 \) allows for a second order Darboux displacement if and only if the potential \( V_0(x) \) satisfies the following differential–difference equation:

\[ T - \frac{1}{4} \left[ \frac{T'}{M} \right]^2 = \text{constant}, \]

(3.12)

where

\[ T = (S'/D)^2 + 4S - 2D''/D, \quad M = D - (S'/D)', \]

(3.13)

and

\[ S = V_0(x) + V_0(\bar{x}), \quad D = V_0(x) - V_0(\bar{x}). \]

(3.14)

Note that this formula resembles (2.13) for the first order displacement, but the functions \( T \) and \( M \) involved depend in a much more complex way on \( V_0(x) \).

Proof. Since \( u'' = [(u'/u)' + (u'/u)^2]u \), the Schrödinger equation for \( u_2^- \) is

\[ \left[ \frac{(u^-_2)'}{u_2} \right]' + \left[ \frac{(u^-_2)'}{u_2} \right]^2 + a_2 - V_0(x) = 0 , \]

(3.15)

which together with (3.8) results in

\[ 2pp'' - (p')^2 + \frac{1}{4}p^4 + 4(a_1 - a_2)^2 + 2p^2(a_1 + a_2 - S) = 0 , \]

(3.16)
where $S$ is defined in (3.14). Now we take the derivative of (3.16) and, since $p' = V_0(x) - V_0(x + d)$ is a known function, we can treat the result as a quadratic equation for $p$, whose solution is

$$p = \frac{S'}{p'} \pm \sqrt{\left(\frac{S'}{p'}\right)^2 - 2\frac{p''}{p'} + 4S - 4(a_1 + a_2)}.$$  
(3.17)

Then taking the derivative of (3.17) and rearranging, we obtain the nonlinear differential-difference equation for $V_0(x)$

$$4(a_1 + a_2) = T - \frac{1}{4} \left[ \frac{T'}{D - (S'/D)'} \right]^2$$  
(3.18)

where $T$ is defined by (3.13). Keeping in mind that the eigenvalues $a_1$ and $a_2$ are independent of $x$ and taking into consideration the definition of $M$ (second formula in (3.13)), we see that the necessary condition is fulfilled. We shall show now that this condition is also sufficient.

First, we notice that by using (3.18) to eliminate $a_1 + a_2$ in (3.17) we find

$$p = \frac{S'}{D} + \frac{1}{2} \frac{T'}{D - (S'/D)'}.$$  
(3.19)

Here we have to choose only plus sign in (3.17) since it is easy to see that the minus contradicts the condition $p' = V_0(x) - V_0(x + d)$. If the right hand side of (3.18) is constant, then from (3.19) we obtain $p$ which, by retracing our steps, satisfies (3.16) which is equivalent to the Schrödinger equation (3.15) for $u^{-2}$. Therefore, from (3.8) and (3.9), we have the logarithmic derivatives of $u^{-2}$ and $u^{2}$. These being known, we are able to calculate the second logarithmic derivative of their Wronskian

$$[\ln W]'' = (a_1 - a_2)\frac{[\ln(u_1^+/u_2^+)]''}{[\ln(u_1^+/u_2^+)]'} - \left( \frac{a_1 - a_2}{[\ln(u_1^+/u_2^+)]'} \right)^2 = \frac{1}{2} D,$$  
(3.20)

which by (2.6) means that $h_0$ possesses a second order Darboux displacement. \qed

**Corollary 1** Any 2-SUSY invariant potential allowing a set of displacements $d$ generates a one-parameter family of 2-SUSY invariant potentials (some of them may have singular points) obtained by a 1-SUSY transformation with one of the four function $u_1^\pm$, $u_2^\pm$ as transformation function.

**Proof.** Let $V_0(x)$ be 2-SUSY invariant. This means that there exists a second order Darboux transformation with transformation functions $u_1^-$ and $u_2^+$ which results only in a displacement of the transformed potential $V_2(x) = V_0(x + d)$. Any second order transformation may be factored into two successive first order transformations. One can realize the first transformation with the transformation function $u_1^-$ to get an intermediate potential $V_1(x)$ which cannot be obtained by a
displacement of $V_0(x)$ if the later is not 1-SUSY invariant and hence $V_1(x)$ is essentially different of $V_0(x)$. We shall show that $V_1(x)$ allows for the same second order Darboux displacement. In order to show this property take the logarithms of the first equality in (3.3)

$$2 \log W(x) + 2 \log u_1^{-}(x + d) = 2 \log c_1 + 2 \log u_2^{-}(x).$$

After taking two derivatives and using (2.6) and (3.1) we obtain

$$V_0(x) - 2|\log u_2^{-}(x)|'' = V_0(x + d) - 2|\log u_1^{-}(x + d)|''. \quad (3.21)$$

The left hand side of this equality means that we realize a 1-SUSY transformation of the potential $V_0$ with the transformation function $u_2^{-}(x)$ and from the right hand side we learn that a similar transformation is realized of the shifted version of the same potential with the transformation function $u_1^{-}(x + d)$. Since the Darboux transformations are invertible, we see that these transformed potentials may always be related to each other with the help of a 2-SUSY transformation for which $V_0$ is an intermediate potential. Hence, the equality (3.21) means that after such a transformation we get only a displacement by the value $d$. If the function $u_2^{-}(x)$ has nodes, the 1-SUSY partner of $V_0(x)$ will have singularities (poles). To displace $V_0(x)$ by another value we have to choose a second pair of transformation functions $u_1^{+}$ and $u_2^{-}$ that give us another member of the family of 2-SUSY invariant potentials.

**Remark 2** No member of the family obtained above is a displaced copy of the initial potential if it is not 1-SUSY invariant. Moreover, few of the potentials are displaced copies of other members of the same family, which means that the whole set of 2-SUSY invariant potentials is quite rich.

Indeed, if the initial potential is not 1-SUSY invariant it is not possible to displace it by a 1-SUSY transformation. Next, any two different members of this family are related by a 2-SUSY transformation, where $V_0$ is an intermediate potential. The factorization parameters of such a transformation are independent of each other, which means that once a representative of the family is fixed, $\tilde{V}$, the whole family is characterized by two independent (factorization) parameters. The potential $\tilde{V}$, being 2-SUSY invariant, also admits 2-SUSY transformations resulting only in a displacement, but these transformations are characterized by one parameter only. This follows from equations (3.16) and (3.18) which may be considered as defining one of the factorization constants (say $a_2$) as an implicit function of the other ($a_1$). This property will also be illustrated in the next Section and used in the Section 5 to produce new exactly solvable periodic potentials.
Remark 3 The results of this Section are valid not only for a periodic potential but for any potential satisfying the conditions of Proposition 1.

This follows from the fact that the only place where we used the Bloch property of solutions of the Schrödinger equation (that is the periodicity of the potential $V_0(x)$) is in formula (3.2). Thus, $u_1^\pm$ and $u_2^\pm$ can be not only Bloch solutions, but two pairs of linearly independent solutions of the Schrödinger equation with a non-periodic potential.

A simple sufficient condition for (3.12) is that $T = (S'/D)^2 + 4S - 2D''/D$ be constant. For example, consider the 1-SUSY invariant potential $V_0(x) = 2\wp(x - \omega')$. From the differential equation for $\wp$, we obtain $V_0'' = 3V_0^2 - g_2$ and therefore $D'' = 3V_0''(x) - 3V_0''(x + d) = 3DS$. From (2.13), the 1-SUSY invariance requires $(S'/D)^2 = 2S + \text{const}$. Therefore, in this case, $T = (S'/D)^2 - 2S = \text{const}$ and, consequently, $V_0$ is also 2-SUSY invariant, which of course was evident from the outset.

Note that for even potentials, $V_0(-x) = V_0(x)$, the expression in square brackets in (3.12) is not defined for $x = -d/2$. Using Mathematica [12] we have found that in this case

$$\lim_{x \to d/2} \frac{1}{4} \left[ \frac{T'}{D - (S'/D)^2} \right]^2 = \frac{12(V_0')^3 V_0'' + (V_0'')^2 V_0'' - V_0'[V_0''(V_0')^2 + V_0''V_0^{(IV)}] + (V_0'')^2 V_0^{(V)}}{V_0'[6(V_0')^3 + V_0''V_0'' - V_0'V_0^{(IV)}]},$$

where all the functions in the right hand side are evaluated at $x = d/2$.

4. Two-soliton potentials

In this section we illustrate our previous developments for a well-studied two-soliton potential. In its most general form this potential is determined by four parameters:

$$V_0(x) = \frac{2(\alpha_1^2 - \alpha_2^2)(\alpha_1^2 \text{sech}^2(\alpha_1 x + \beta_1) + \alpha_2^2 \text{csch}^2(\alpha_2 x + \beta_2))}{[\alpha_1 \text{tanh}(\alpha_1 x + \beta_1) - \alpha_2 \text{coth}(\alpha_2 x + \beta_2)]^2}. \quad (4.1)$$

The parameters $\alpha_2 > \alpha_1 > 0$ define the positions of the discrete levels $E_{0,1} = -\alpha_2^2$, while $\beta_1$ and $\beta_2$ characterize isospectral deformations. It has been shown by direct calculation [4] that the symmetrical case, $\beta_1 = \beta_2 = 0$, is 2-SUSY invariant. We note that exactly the same calculations can be carried out for the general case, indicating that for any fixed values of the parameters $\alpha_{1,2}$ and $\beta_{1,2}$ the potential (4.1) is 2-SUSY invariant. This illustrates Remark 3. With evident modifications of the results of [4] we give the solutions $u_1^+$ and $u_2^-$ producing the second order Darboux displacement $d$ of $V_0$:

$$u_{1,2}^\pm = W(u_{10}, u_{20}, u_{30,40}) W^{-1}(u_{10}, u_{20}),$$
where \( u_{10} = \cosh(\alpha_1 x + \beta_1) \), \( u_{20} = \sinh(\alpha_2 x + \beta_2) \) are solutions of the free particle Schrödinger equation generating the potential (4.1) from the zero potential, and \( u_{30,40} = \exp(\alpha_{3,4} x) \), \( \alpha_{3,4} > 0 \). When parameters \( \alpha_3 \) and \( \alpha_4 \) vary in a certain domain, independently of each other, these functions produce an isospectral deformation of \( V_0 \), resulting in the same expression with the different values of \( \beta_1 \) and \( \beta_2 \). To select from these transformations only ones leading to the shift \( V_0(x) \rightarrow V_2(x) = V_0(x + d) \) one has to impose an additional restriction on \( \alpha_3 \) and \( \alpha_4 \). The analysis in reference [4] shows that to get real displacements one has to change the factorization constants \( \alpha_3 \) and \( \alpha_4 \) so that they fall between the existing discrete levels of \( V_0 \): \( \alpha_1 < \alpha_3 < \alpha_4 < \alpha_2 \).

Let us now characterize the one-parameter family mentioned in Corollary 1. For this purpose we have to realize a 1-SUSY transformation of the potential \( V_0 \) by using one of \( u_{1,2}^\pm \) as the transformation function. For simplicity let us fix \( \beta_1 = \beta_2 = 0 \) and choose the function \( u^+_3 \) to produce the potential \( V_1 \). According to properties of Darboux transformations (see e.g. [9]) this is equivalent to a third order transformation of the zero potential with transformation functions \( u_{10}, u_{20} \) and \( u_{30} \) or simply to a chain of transformations where, for instance, the first transformation is realized with the function \( u_{30} \). For such a transformation the zero potential is not affected, but the functions \( u_{10} \) and \( u_{20} \) receive changes and, up to a constant factor, become \( u_{10}(x) \rightarrow v_{10}(x) = \cosh(\alpha_1 x + \gamma_1), \quad u_{20}(x) \rightarrow v_{20}(x) = \sinh(\alpha_2 x + \gamma_2), \) where

\[
\gamma_1 = \text{arctanh} \left( \frac{\alpha_1}{\alpha_3} \right), \quad \gamma_2 = \text{arctanh} \left( \frac{\alpha_2}{\alpha_3} \right).
\] (4.2)

After the second order transformation with the functions \( v_{10} \) and \( v_{20} \) we get from the zero potential the same two-soliton potential (4.1) where \( \beta \)'s are replaced by \( \gamma \)'s. This is just the 1-parameter family of Corollary 1 where \( \alpha_3 \) is the parameter. From the definition (4.2) we see that the parameters \( \gamma_1 \) and \( \gamma_2 \) are not independent of each other: \( \tanh \gamma_1 / \tanh \gamma_2 = \alpha_1 / \alpha_2 \). They vary so that the potential \( V_1 \) cannot be reduced to a displaced copy of the potential (4.1) at \( \beta_1 = \beta_2 = 0 \), since the later condition requires \( \alpha_1 / \alpha_2 = \gamma_1 / \gamma_2 \), which leads to \( \tanh \gamma_1 / \tanh \gamma_2 = \gamma_1 / \gamma_2 \). The later is possible only for \( \gamma_1 = \gamma_2 \) which contradicts to \( \alpha_1 \neq \alpha_2 \). Just from this, the potential \( V_1 \), being of course a two-soliton potential, is essentially different from \( V_0 \), as pointed out in Remark 2.

We will illustrate other properties derived in the previous section for the simplest case of this potential. We choose \( \alpha_1 = 1 \) and \( \alpha_2 = 2 \) to produce the well-known Pöschl-Teller potential well

\[
V_0(x) = -6 \text{sech}^2 x
\] (4.3)

for which \( E_0 = -4 \) and \( E_1 = -1 \).
From (3.13) we find the value of $T$,

$$T = 4 \left[ -1 + \text{csch}^2 d - 4 \text{sech}^2 x - 4 \text{sech}^2 (d + x) \right], \tag{4.4}$$

which after being substituted into Eq. (3.18) gives the $x$-independent quantity

$$a_1 + a_2 = -5 - 3 \text{csch}^2 d. \tag{4.5}$$

This means that the necessary and sufficient conditions for $V_0$ (1.3) to be 2-SUSY invariant are fulfilled. Now from (3.19) we obtain $p(x) = -6[\tanh x + \text{csch} \ cosh x \ \text{sech} (x + d)]$. From Eq. (3.16) we deduce the difference of the factorization constants

$$a_1 - a_2 = \pm (3 \coth d \sqrt{1 - 3 \text{csch}^2 d}). \tag{4.6}$$

From here and (4.5) one gets one factorization constant as a function of the other: $a_1 = \frac{1}{2} (-6 - a_2 \pm \sqrt{-12a_2 - 3a_2^2})$. It is clear that this equation and (4.5) define the displacement $d$ as a function of $a_2$:

$$d = \text{arccsch} \sqrt{-4 - a_2 + \sqrt{3 \sqrt{-a_2(a_2 + 4)}} \sqrt{6}}. \tag{4.7}$$

It follows from here that real displacements are possible only when both factorization constants lie between discrete levels, $-4 < a_{1,2} < -1$, and in the above formula for $a_1$ the lower sign is chosen. This agrees completely with the previous result [4]. We see also that when $a_1 \to -3$, then $a_2 \to -3$, and we get the minimal value of the displacement $d_{\text{min}} = \text{arccosh} (1/\sqrt{3})$. The other limit is $a_1 \to -4$, which gives $a_2 \to -1$, so that the displacement increases indefinitely, $d \to \infty$. In this respect we remark that for 1-soliton potentials the (first order Darboux) displacements range is always $(0, \infty)$.

We are able now to find the right hand side of equation (3.8). It is expressed in terms of elementary functions only and its primitive gives us a solution of the Schrödinger equation with the potential $V_0$:

$$u_2(x) = \cosh(x + d)e^{-\frac{1}{2}(3 \coth d + \sqrt{1 - 3 \text{csch}^2 d})}[3 - \cosh 2d + \cosh 2x + \cosh(2x + 2d)]^{1/2}$$

$$\times \ \text{sech}^2 x \left[ \begin{array}{c}
\sqrt{2}(\coth d + 2 \tanh x) \sinh d + \sqrt{\cosh 2d - 7} \\
- \sqrt{2}(\coth d + 2 \tanh x) \sinh d + \sqrt{\cosh 2d - 7}
\end{array} \right]^{1/2}. \tag{4.8}$$

The derivative of this expression yields the potential difference as a function of the parameter $d$:

$$\Delta V = [(4 \cosh x \ \text{csch} \ d \ \text{sech} (x + d) + \tanh x)(\text{sech}^2 (x + d) \ \tanh(x + d) + 2 \text{sech}^2 x \ \tanh x)$$
Second Order Darboux Displacements

\[ + \left( \text{sech}^2(x + d) - \text{sech}^2 x \right)(3 \text{csch}^2 d + \coth d \sqrt{1 - 3 \text{csch}^2 d} \right) \]  
\[ - \text{sech}^2 x - 2 \text{sech}^2(x + d) + 3 \tanh^2 x) \right) \right] \frac{\sqrt{a_2} \tanh x}{\sqrt{a_2} \sinh 2x} \right) \] 
\[ \times \left[ a_2 - 4 + (a_2 + 2) \cosh 2x + 3a_2 \sinh 2x \right]^{-2}. \]  

(4.10)

Of course, this intermediate quantity can be eliminated from the final expression to obtain a somewhat simpler formula for the family of two-soliton potentials:

\[ V_1(x) = 12 \left[ 4 + 9a_2 - a_2^2 - 6 \text{sech}^2 x + 12 \sqrt{a_2} \tanh x \right. \] 
\[ - (a_2 - 1)((a_2 + 4) \cosh 2x + 4 \sqrt{a_2} \sinh 2x) \] 
\[ \times \left[ a_2 - 4 + (a_2 + 2) \cosh 2x + 3a_2 \sinh 2x \right]^{-2}. \]  

(4.10)

Figure 1: Two soliton Pöschl-Teller potential (dashed line) and its SUSY partner at \( a_2 = -4.1 \).

For the potential difference to be regular one has to choose the factorization constant \( a_2 \) to be less than the ground state level of \( V_0 \), \( a_2 < -4 \), which gives complex values for the parameter \( d \). Despite this, the potential difference is real and the solution [4.8] is also real (and nodeless) if it is set real at any point, i.e. \( u_2^\ast (0) = 1 \). As an example we have plotted one of the potentials \( V_1 = V_0 + \Delta V \) with \( \Delta V \) as in [4.9] in the Fig. 1 (solid line) along with \( V_0 \) (dashed line).

5. The Lamé-Ince potential

A much more interesting example of second order Darboux displacements is given by the following result.

**Proposition 2** The periodic two-gap potential

\[ V_0(x) = 6 \wp(x + \omega') \]  

(5.1)

where \( \omega' \) and \( \omega \) are the imaginary and real half-periods of the Weierstrass function \( \wp \), with \( g_2 \) and \( g_3 \) as invariants, allows for second order Darboux displacements. The eigenvalues \( a_{1,2} \) of
the transformation functions producing the displacement \(d\) are given by

\[
a_{1,2} = -\frac{3}{2} \left[ \wp(d) \mp \sqrt{g_2 - 3\wp^2(d)} \right].
\] (5.2)

**Proof.** The proof consists simply in calculating the left hand side of the equation \((3.12)\). We obtain first some useful relations between our variables which are direct implications of the well-known properties of the Weierstrass functions (see e.g. [5]). From the differential equation for \(\wp\) one gets

\[
D'' = SD',
\]

so

\[
T = \left( \frac{S'}{D} \right)^2 + 2S.
\]

The addition formula for \(\wp\) is

\[
\wp(u + v) + \wp(u) + \wp(v) = \frac{1}{4} \left[ \wp'(u) - \wp'(v) \right]^2.
\] (5.3)

By setting \(u = x + \omega' + d\), \(v = -x - \omega'\) and noting that \(\wp\) is even, this translates into

\[
(S'/D)^2 = \frac{2}{3} S + 4\wp(d) \quad \text{and} \quad T = \frac{8}{3} S + 4\wp(d).
\]

By taking the square root of the former of these relations and differentiating, we get

\[
\frac{1}{D} \left( \frac{S'}{D} \right)' = \frac{1}{3},
\] (5.4)

and

\[
T' = 8S'/3, \quad D - (S'/D)' = 2D/3.
\]

Inserting these relations into \((3.17)\) yields

\[
p = 3(S'/D).
\] (5.5)

Now we are able to calculate the left hand side of \((3.12)\) which gives

\[
a_1 + a_2 = -3\wp(d).
\] (5.6)

This proves the first part of the statement. Now we shall find the eigenvalues of the transformation functions. For this purpose we shall use the equation \((3.16)\). Since \([\wp'(x)]^2 = 4\wp^3(x) - g_2\wp(x)\), we have the algebraic identity

\[
D^2 - 6\frac{S'D'}{D} + 3S^2 = 36g_2,
\] (5.7)

and since \(p = 3S'/D\), inserting it and \((5.6)\) in \((3.16)\) and taking into account \((5.7)\) we obtain

\[
(a_1 - a_2)^2 = 9[g_2 - 3\wp^2(d)].
\] (5.8)

This equality together with \((5.6)\) proves the statement. One can check that formulas \((5.6)\) and \((5.8)\), for the sum and difference of factorization constants, reduce to those for the specific case of the two-soliton potential \((4.5)\) and \((4.6)\), respectively, when we take the half periods \(\omega' = i\pi/2\) and \(\omega = \infty\).

□

Some straightforward consequences of Proposition 2 are:
Corollary 2 Three of the five band edges for the potential \((5.1)\),

\[ E_1 = 3e_3, \quad E_{1'} = 3e_2, \quad E_2 = 3e_1 \tag{5.9} \]

correspond to \(d = \omega, \ d = \omega + \omega'\) and \(d = \omega'\), where

\[ e_1 = \wp(\omega), \quad e_2 = \wp(\omega + \omega'), \quad e_3 = \wp(\omega'). \tag{5.10} \]

The lowest \(E_0 = -\sqrt{3g_2}\) and the highest \(E_{2'} = \sqrt{3g_2}\) band edges are stationary points for the factorization constants \(a_1\) and \(a_2\) as functions of the displacement \(d\).

Corollary 3 The pair of (real) factorization constants which give rise to a real displacement by means of a second order Darboux transformation belong to the first finite forbidden band \([E_1, E_{1'}]\). The real displacements so produced are in the interval \((d_{\min}, d_{\max})\), where

\[ d_{\min} = \wp^{-1}(\sqrt{g_2/3}), \quad d_{\max} = \omega. \tag{5.11} \]

\(\wp^{-1}(t)\) is the function inverse to \(t = \wp(z)\) for which an appropriate sheet has to be chosen; \(d_{\max} = \omega\) is realized for \(a_2 = E_1\) and \(a_1 = E_{1'}\), while \(d_{\min}\) is realized for \(a_1 = a_2 = -\sqrt{3g_2/2}\).

It is interesting to note that \(-e_k\) are the positions of the band edges for the one-gap potential \(V_0 = -2\wp(x + \omega')\) and that in this case the range of the (first order) Darboux displacements is \((0, \infty)\).

Proof. The first part of Corollary 2 follows immediately from Proposition 2 and known properties of the quantities \(e_k\) given in Ref. [5] (vol. 2), when one uses \(d = \omega, \ d = \omega + \omega'\) and \(d = \omega'\). The second one is a direct consequence of \((5.2)\) and conditions \(a'_{1,2}(d) = 0\). Corollary 3 follows from the restriction on \(d\) to be such that \(g_2 - 3\wp^2(d)\) be positive, since according to Proposition 2 it is inside of the square root. \(\square\)

It is not difficult to see that for \(d = \omega\), the factorization constants are \(a_2 = E_1\) and \(a_1 = E_{1'}\). This is the only possibility for the transformed potential to be displaced by half a real period of the Weierstrass \(\wp\) function. The possibility for the potential \((5.1)\) to be displaced by a half-period was previously noticed in [1, 2]. Here we indicate a possibility of displacing the argument of the potential \((5.1)\) by a complex value and, in particular, by half an imaginary period. We remark that the values for the band edges are given in [2] for the Jacobi form of the Schrödinger equation, which we relate to the Weierstrass form in Appendix A.

We are now able to integrate equations \((3.8)\)–\((3.11)\) and find analytic expressions for the Bloch functions, as it is established in the following proposition.
Proposition 3 The functions
\[ u_2(x) = \pm \sqrt{p} \left( \frac{\sigma(x + \omega + d)}{\sigma(x + \omega')} \right)^{3/2} \left( \frac{\sigma(x - x_1)}{\sigma(x - x_2)} \right)^{1/2} e^{(b - \frac{1}{2} \zeta(d)) x} \] (5.12)
\[ u_2^\pm(\tilde{x}) = \frac{p(x)}{u_2(x)} \] (5.13)
are the Bloch eigenfunctions for the Hamiltonian (5.1) with the eigenvalue \( a_2 \), and
\[ u_1^-(\tilde{x}) = u_2(x) \left( \frac{\sigma(x + \omega')}{\sigma(x + \omega' + d)} \right)^3 e^{3 \zeta(d) x} \] (5.14)
\[ u_1^+(x) = \frac{p(x)}{u_1(x)} \] (5.15)
are the Bloch eigenfunctions with the eigenvalue \( a_1 \). Here \( \sigma \) and \( \zeta \) are standard Weierstrass functions,
\[ x_1 = \wp^{-1} \left( -\frac{1}{2} \wp_0 + \frac{1}{2} \sqrt{g_2 - 3 \wp_0^2} \right) - \omega' \]
\[ x_2 = \wp^{-1} \left( -\frac{1}{2} \wp_0 - \frac{1}{2} \sqrt{g_2 - 3 \wp_0^2} \right) - \omega' \] (5.16)
\( \wp_0 = \wp(d) \), \( \wp^{-1} \) is the function inverse to \( \wp \) and
\[ b = \frac{1}{2} \zeta(\omega' - x_2) - \frac{1}{2} \zeta(\omega' - x_1). \] (5.17)
The proof can be found in Appendix B.

Remark 4 The solutions given in (5.12) and (5.13) are valid for any eigenvalue \( a_2 \). By using (5.2) one can find \( a_1 \) as a function of \( a_2 \):
\[ a_1 = \frac{-a_2 \pm \sqrt{9g_2 - 3 a_2^2}}{2}. \] (5.18)
Then with the aid of (5.6) \( d \) is expressed in terms of \( a_2 \) also. Hence, the Bloch functions (5.12) and (5.13) are determined only by the eigenvalue \( a_2 \) which can take any value and, thus, these functions generate the 1-parameter family of 2-SUSY invariant potentials mentioned in Corollary 1. With appropriate modifications the same is true for the functions (5.14) and (5.15).

To illustrate this Remark we prove:

Proposition 4 The potentials
\[ V_1(x) = V_0(x) + \Delta V(x), \quad V_0(x) = 6\wp(x + \omega'), \] (5.19)
where
\[
\Delta V(x) = -\left[\varphi(x + \omega' + d) + \varphi(x + \omega')\right]^2 + 2\varphi(x + \omega' + d)\varphi(x + \omega') - g_2/2
\]
\[
+ 3\varphi(x + \omega' + d) - 3\varphi(x + \omega') - \varphi(x - x_1) + \varphi(x - x_2),
\]
(5.20)
d = \varphi^{-1}(-\frac{a_1 + a_2}{3}), x_1, x_2 are defined as in (5.16), and \(a_1\) in (5.18), form a one-parameter family of real-valued two-gap potentials isospectral with \(V_0\). The role of the parameter is played by \(a_2 \leq E_0\), where \(E_0 = -\sqrt{3}g_2\) is the lowest band edge for \(V_0\).

**Proof.** The proof consists simply in calculating the right hand side of Eq. (3.8) and taking its derivative which will give us the potential difference (see (2.4)). Using the expression (B.2) below for \(p\) in terms of the Weierstrass \(\zeta\) function and the addition formula (5.3) we first get
\[
\frac{1}{2}(\log p)' = \frac{(\varphi - \tilde{\varphi})^2}{\varphi' + \tilde{\varphi}^2},
\]
(5.21)
where \(\varphi \equiv \varphi(x + \omega')\) and \(\tilde{\varphi} \equiv \varphi(x + \omega' + d)\). To derive the final expression (5.20) we have used the formula (B.8) and the following properties of the Weierstrass functions: \((\varphi')^2 = 4\varphi^3 - g_2\varphi - g_3\), \(\varphi'' = 6\varphi^2 - g_2/2\) and \(\zeta'(x) = -\varphi(x)\). The fact that these potentials have two-gaps follows from the fact that Darboux transformations preserve band structure (see e.g. [11]).

It is interesting to observe that different representatives of this family look like displaced copies of the initial potential (see Fig. 1 A) though \(V_0\) is not 1-SUSY invariant which is clearly seen from Fig. 1 B, where the left hand side of equation (2.13) is plotted.

![Figure 2: (A) Lamé-Ince potential (solid line) at \(\omega = 1\) and \(\omega' = 2i\) and its SUSY partners. Dotted line corresponds to \(a_2 = -5\) and dashed line to \(a_2 = -6\); (B) illustrates that the left hand side of the equation (2.13) is not constant for \(d = 1.3\).](image-url)
Figure 3 shows a non-periodic potential obtained when a linear combination of the functions (5.12) and (5.13) is chosen as the transformation function. We stress that it possesses an energy level at $-5.2$ and the solution of the corresponding Schrödinger equation can easily be obtained by applying the first order Darboux transformation operator (2.5) to the functions (5.12)–(5.15). We would also like to mention that the transformed potential tends to a displaced version of the initial potential at large values of $|x|$. This effect, first noticed in [3], illustrates a nonlocal deformation produced by a Darboux transformation.

Finally, we would like to point out that the function (5.12) acquires a constant factor when its argument increases by the period $2\omega$. This can be seen from properties of the Weierstrass $\sigma$ functions [5] that lead to

$$u_2^-(x + 2\omega) = u_2^-(x) \exp[\zeta(\omega)(3d + x_2 - x_1) - \omega(3\zeta(d) - 2b)].$$

From here it follows, in particular, that for $a_2 = 3e_3$, $a_1 = 3e_2$, one has $d = \omega$, $x_1 = \omega$ and $x_2 = -2\omega'$ which results in the condition $u_2^-(x + 2\omega) = u_2^-(x) \exp[2\zeta(\omega')\omega - 2\omega'\zeta(\omega)] = -u_2^-(x)$, where we have used the Legendre relation [5]. This result agrees with the fact that this function corresponds to the second band edge.

In conclusion, we have characterized and investigated the interesting class of periodic potentials which are merely translated by a second order Darboux transformation. We have presented several examples, concentrating on the fascinating family of two-gap Lamé-Ince potentials. The nonlinear differential equation which must be satisfied by all such potentials, which may be related to the class of Painlevé equations, deserves further investigation.

BFS would like also to thank the Physics Department of CINVESTAV, where this work was started in the spring of 2001, for kind hospitality.

Appendix A

Here, to fix our notation, we relate the Weierstrass form of the Schrödinger equation to its Lamé form (see also [5], vol. 3). According to [5] one has

\[ sn^2(z, k) = \frac{e_1 - e_3}{\wp(x) - e_3}, \quad \wp(x + \omega') = e_3 + \frac{(e_3 - e_2)(e_3 - e_1)}{\wp(x) - e_3} \] (A.1)

or

\[ \wp(x + \omega') = e_3 + (e_2 - e_3)sn^2(z, k), \] (A.2)

where

\[ k^2 \equiv m = \frac{e_2 - e_3}{e_1 - e_3}, \quad z = (e_1 - e_3)^{1/2}x. \] (A.3)

Now, after replacing the variable \( x \) by \( z \) in the Schrödinger equation with the potential [5], one gets

\[ \left[ -\frac{d^2}{dz^2} + (6k^2sn^2(z, k) - \tilde{E}) \right] \psi = 0, \] (A.4)

where

\[ \tilde{E} = \frac{E - 6e_3}{e_1 - e_3} = \frac{E}{e_1 - e_3} + 2m + 2. \] (A.5)

Using this relation and Corollary 2 one recovers the known band edges for the Lamé equation (see e.g. [2]),

\[ \tilde{E}_0 = \frac{E_0 - 6e_3}{e_1 - e_3} = 2m + 2 - 2\delta, \]
\[ \tilde{E}_1 = m + 1, \quad \tilde{E}_1' = 4m + 1, \]
\[ \tilde{E}_2 = m + 4, \quad \tilde{E}_2' = 2m + 2 + 2\delta. \] (A.6)
Appendix B

In this Appendix we prove Proposition 3. In our notation the addition theorem for the Weierstrass $\zeta$–function (see [5])

$$\frac{1}{2} \frac{\wp'(x + d) + \wp'(x)}{\wp(x + d) - \wp(x)} = \zeta(x) - \zeta(x + d) + \zeta(d)$$  \hspace{1cm} (B.1)

becomes

$$\frac{1}{2} \frac{S'}{D} = \zeta(x + \omega' + d) - \zeta(x + \omega') - \zeta(d).$$

Hence

$$p = 3 \frac{S'}{D} = 6[\zeta(x + \omega' + d) - \zeta(x + \omega') - \zeta(d)].$$  \hspace{1cm} (B.2)

Recalling that

$$p^2 = 9 \left( \frac{S'}{D} \right)^2 = 6S + 36\wp(d)$$  \hspace{1cm} (B.3)

we find

$$S = 6[\wp(x + \omega') + \wp(x + \omega' + d)].$$  \hspace{1cm} (B.4)

Let us find now the expression for $1/p$.

The function $S$ has second order poles at the same points as $\wp(x + \omega')$ and $\wp(x + \omega' + d)$, that is at $x = -\omega'$ and $x = -\omega' - d$. This means that $S$ is a second order elliptic function and has two second order zeros. Here and below, for simplicity, we suppose that $d$ falls in the interval $(d_{\min}, d_{\max})$ indicated in Corollary 3.

Let us denote

$$f(x) := \wp(x + \omega') + \wp(x + \omega' + d) + \wp(d).$$  \hspace{1cm} (B.5)

Then $p^2 = 36f \geq 0$ for real values of $\wp$. Note that for $d = \omega$, $f(0) = f(\omega) = e_1 + e_2 + e_3 = 0$. Hence, $x = 0$ and $x = \omega$ are the points of local minima for $f(x)$. Therefore $f'(0) = f'(\omega) = 0$, i.e. the zeros are of second order. Next, it is easy to see that $f'(\omega/2) = f'(3\omega/2) = 0$ and the points $x = \omega/2$ and $x = 3\omega/2$ are the points of local maxima for real valued $f(x)$. We find now the positions of these zeros.

Let $x_0$ be a minimum (or a zero-point) for $f(x)$, that is $f(x_0) = 0$ and $f'(x_0) = 0$. Let us abbreviate the notation by putting

$$\wp := \wp(x_0 + \omega'), \hspace{0.5cm} \tilde{\wp} := \wp(x_0 + \omega' + d), \hspace{0.5cm} \wp_0 := \wp(d).$$
Then $\varphi + \tilde{\varphi} + \varphi_0 = 0$ and $\varphi' + \tilde{\varphi}' = 0$ (with the evident notation $\varphi' = \varphi'(x_0)$, ...). Or else $\varphi'^2 - \tilde{\varphi}'^2 = 0$. Using the differential equation for $\varphi$, $\varphi'^2 = 4\varphi^3 - g_2\varphi - g_3$, one finds from here that

$$(\varphi - \tilde{\varphi})(4\varphi^2 + 4\tilde{\varphi}^2 + 4\varphi\tilde{\varphi} - g_2) = 0.$$  

Since $\varphi \neq \tilde{\varphi}$ this implies that

$$0 = 4\varphi^2 + 4\tilde{\varphi}^2 + 4\varphi\tilde{\varphi} - g_2 = 4\varphi_0^2 + 4\varphi\varphi_0 - g_2$$

and

$$\varphi(x_0 + \omega') = -\frac{1}{2}\varphi_0 \pm \frac{1}{2}\sqrt{g_2 - 3\varphi_0^2}.$$  

(B.6)

Hence, the positions $x_1$ and $x_2$ of the zeros of $f(x)$ are given by (5.16). In using these formulas it is necessary to keep in mind that $\varphi$ is a multisheet function. Note, that for $d = \omega$ one gets $x_2 = 0$ and $x_1 = \omega$ since $\sqrt{g_2 - 3\varphi_0^2} = e_2 - e_3$, $\varphi^{-1}(e_3) = \omega'$, $\varphi^{-1}(e_2) = \omega + \omega'$. Note also that since the equation $\varphi(z) = A$ defines $z$ up to a sign and up to the periods, either the sum or the difference of $x_1$ and $x_2$ modulo periods is equal to $-d$.

The function $p(x) = \pm 6\sqrt{f(x)}$ has simple zeros $x_1$ and $x_2$ and simple poles $1/p(x)$. It is not difficult to find the residues of $1/p(x)$ at these points

$$\text{Res}_{x=x_1} \frac{1}{p(x)} = -\text{Res}_{x=x_2} \frac{1}{p(x)} = \frac{1}{6\sqrt{g_2 - 3\varphi_0^2}}.$$  

(B.7)

This implies that the residues of $(a_1 - a_2)/p$ at the points $x_{1,2}$ are $\pm 1/2$.

Now, using the known decomposition of an elliptic function in terms of $\zeta$ functions one finds

$$\frac{a_1 - a_2}{p} = \frac{1}{2}\zeta(x - x_1) - \frac{1}{2}\zeta(x - x_2) + b.$$  

(B.8)

The constant $b$ here may be calculated by the same formula at $x = \omega'$ where $1/p = 0$. This gives (5.17).

Using the fact that $\sigma'(z)/\sigma(z) = \zeta(z)$ one obtains

$$\frac{a_1 - a_2}{p} = \frac{1}{2} \left[ \log \frac{\sigma(x - x_1)}{\sigma(x - x_2)} \right]' + b$$  

(B.9)

and from (B.2) one finds

$$p = 6 \left[ \log \frac{\sigma(x + \omega' + d)}{\sigma(x + \omega')} \right]' - 6\zeta(d).$$  

(B.10)
With the help of the last two relations one gets from (3.8)

\[
[\log u_2(x)]' = \frac{1}{2} [\log p]' + \frac{1}{4} p + \frac{a_1 - a_2}{p}
\]

(B.11)

\[
= \frac{1}{2} [\log p]' + \frac{3}{2} \left[ \log \frac{\sigma(x + \omega' + d)}{\sigma(x + \omega')} \right]' - \frac{3}{2} \zeta(d) + \frac{1}{2} \left[ \log \frac{\sigma(x - x_1)}{\sigma(x - x_2)} \right]' + b.
\]

It follows from here that (5.12) is a quadrature of the above formula. Similarly, the formulae (5.13)–(5.15) follow from (5.12) and (3.9)–(3.11), and the proposition is proved.
