INTRODUCTION

In colon cancer, radical surgery including lymph node dissection up to the origin of the feeding artery is commonly considered as a standard procedure. This principle is based on the sequential lymphatic spread of colon cancer. In cases of early colon cancer, the extent of lymph node dissection can be decreased because early colon cancer including T1 or T2 has a 0% to 20% chance of lymph node metastasis [1-3]. Therefore, the optimal extent of lymph node dissection depends on the clinical stage of colorectal cancer.

However, there are some reports about skip metastasis beyond principle lymph node is very rare. This is a case of early cecal cancer with skip metastasis to portocaval and retropancreatic space, without regional lymph node metastasis. A 69-year-old female diagnosed as cecal adenocarcinoma. The imaging study revealed as early cecal cancer without enlargement of regional lymph node. However, there is enlargement of portocaval lymph node and high fluorodeoxyglucose (FDG) uptake in positron emission tomography scan image. Right hemicolecotomy with extended lymph node dissection was done including retropancreatic, portocaval and hepatoduodenal ligament lymph node. Though whole abdominal cavity exploration was done, there was no evidence of other synchronous cancer. The final pathologic findings revealed the poorly differentiated adenocarcinoma with invasion of submucosal layer and focally superficial layer of muscularis propria. Two of total 27 lymph nodes were involved by metastatic adenocarcinoma which were from portocaval and retropancreatic space. The detailed preoperative imaging study could find unexpected lymph node metastasis beyond range of routine lymph node dissection. Even though the preoperative clinical stage is relatively early, the detailed and sufficient evaluation for clinical and imaging findings is important not to ignore skip metastasis.

CASE REPORT

A 69-year-old female with a history of hypertension and diabetes mellitus came to the outpatient clinic due to positive results of a stool occult blood test during a routine health examination. Colonoscopic exam revealed a large villous polyp of about 3 cm in the cecum (Fig. 1). Gross features of the polyp were that of a benign polyp but biopsy results revealed an adenocarcinoma. The level of carcinoembryonic antigen was 2.4 ng/mL, which is within normal limits.

She was referred to the department of general surgery for opera-
Abdominopelvic computed tomography scan revealed cecal cancer without pericolic infiltration, and enlarged necrotic lymph node in portocaval space (Fig. 2). Positron emission tomography-computed tomography (PET-CT) scan showed increased fluorodeoxyglucose (FDG) uptake of proven cecal cancer and enlarged lymph node in the portocaval space (Fig. 3).

Right hemicolectomy with extensive lymph node dissection including portocaval, retropancreatic, hepatoduodenal lymph node was carried out. The portocaval lymph node was quite hard and a grossly metastatic lymph node. The resected portocaval lymph node was sent to the pathology department for frozen-section diagnosis and the result was metastatic adenocarcinoma. Whole abdominal cavity exploration was done including remnant colon, entire small bowel, stomach, and all intraabdominal organs. However, there was no suspicious lesion indicative of metastatic lesion. She was discharged 8 postoperative days later without any complication. The final pathology revealed a poorly differentiated adenocarcinoma. The cancer invaded the submucosa and the focally su-
pericolic, intermediate and principle lymph nodes. The cecal cancer had lymphovascular invasion but not perineural invasion. The patient was finally diagnosed with cecal cancer stage IVa (T2N0M1a) according to the AJCC 7th edition and was scheduled for adjuvant chemotherapy.

DISCUSSION

Lymphatic spread of colon cancer sequentially advances from submucosal lymphoid follicle to pericolic, intermediate and principle lymph node [5]. Therefore, lymph node dissection including principle lymph node is the standard extent for colon cancer [6]. However, in cases of early colon cancer, the extent of lymph node dissection can be minimized because the incidence of lymphatic spread is low. For clinical T1 colon cancer which invades to the submucosal layer, the incidence of lymph node metastasis is approximately 0% to 7% [1,2]. For clinical T2 colon cancer which invades to the muscularis propria, the incidence of lymph node metastasis is 9% to 20% [2,3]. Kobayashi et al. [7] reported that lymph node dissection only to regional lymph nodes is sufficient in cT1N0 colon cancer. Kotake et al. [8] reported that lymph node dissection including regional lymph nodes and intermediate lymph nodes is sufficient in cT1N+ and cT2N0 colon cancer [7].

However, distant lymph node metastasis without regional lymph node metastasis rarely occurs and it is called “skip metastasis” [4,5]. The incidence of skip metastasis is 1% to 3% [9]. Many skip metastases were metastasis to principle lymph node without regional lymph node metastasis. Skip metastasis to distant lymph nodes has rarely been reported. There was a case report of skip metastasis to the external iliac and inguinal lymph node metastasis without regional lymph node metastasis [10]. In cases of cecal cancer, regional lymph nodes and lymph nodes around the ileocolic artery can metastasize preferentially. However, this is a very rare case of skip metastasis to the portocaval and retropancreatic space without regional lymph node metastasis.

During operation, portocaval lymph node was diagnosed as metastatic adenocarcinoma through frozen-section examination. Thorough exploration of the abdominal cavity was done to discover other metastatic lesions. However, there was no evidence of any other primary or metastatic cancer. This metastatic portocaval lymph node can be considered as carcinoma of unknown primary cancer (CUP). The most common type of CUP is known as adenocarcinoma, and possible primary sites are the lung, pancreas, colon, stomach, breast, ovary, and prostate [11]. However, final immunohistochemical stain revealed metastatic adenocarcinoma from colorectal origin in this case.

The colonoscopic finding of this case was considered as early cecal cancer due to its gross appearance. Despite clinically early cancer, detailed and sufficient preoperative evaluation helped detect skip metastasis. PET-CT scan demonstrated enlarged lymph node in the portocaval space and increased FDG uptake. Preoperative evaluation led us to perform radical surgery including portocaval and retropancreatic space dissection, which was essential for R0 resection.

In this report, skip metastasis could have been missed because of clinically early stage and rarity. Furthermore, it suggests that extensive lymph node dissection should be done if distant lymph node metastasis is suggested. Laparoscopic surgery is commonly performed, especially in early colon cancer [12]. However, a limitation of laparoscopic surgery is difficulty in evaluation of the whole abdominal cavity. Therefore, detailed and sufficient preoperative evaluation for clinical and imaging finding is important not to ignore skip metastasis.
