Abstract

Background

The purpose of this study was to investigate the role of microRNA-21 (miR-21) on bevacizumab (BEV)-induced Epithelial-mesenchymal transition (EMT) in retinal pigment epithelial (RPE) cells in vitro.

Methods

Human retinal pigment epithelial cells line (ARPE-19) were exposed to clinical dosage of BEV and miR-21 expression was measured by qRT-PCR assay. The effects of miR-21 on BEV-induced EMT were examined through gain- or loss- expression of miR-21 using miR-21 mimic or inhibitor. The expression of α-smooth muscle actin (α-SMA), E-cadherin, Snail, TGFβ1 and smad2/3 were detected by western blot. TGFβ1/smads2/3 signaling was inhibited by using SB431542 and SIS3.

Results

Clinical dosage of BEV caused EMT and enhanced miR-21 expression in ARPE-19 cells. The inhibition of miR-21 attenuated the EMT effect of BEV, while over-expression of miR-21 promoted this activity. Snail was up-regulated by BEV and the promotion was partially suppressed by miR-21 inhibitor and aggravated by miR-21 mimic. miR-21 regulated BEV-induced TGFβ1 increasing and smad2/3 phosphorylation. The EMT and Snail expression promoted by BEV and miR-21 mimic in ARPE-19 cells was impaired by inhibition of TGFβ1/smads2/3 signaling.

Conclusions

miR-21 promoted BEV-induced EMT in ARPE cells through up-regulating of Snail expression via regulation of TGFβ1/smads2/3 signaling pathway. miR-21 might be a potential miRNA-based therapeutic target in reducing BEV-induced subretinal fibrosis.
Background

Intravitreal injection of anti-vascular endothelial growth factor (VEGF) agents is first line therapy for most of the vasoproliferative ocular diseases such as wet-age related macular degeneration (wAMD), proliferative diabetic retinopathy (PDR) and retinal vein occlusion (RVO) [1,2]. Unfortunately, both long and short-term application of anti-VEGF agents had revealed some unfavorable effects such as tractional retinal detachment and subretinal fibrosis [3-6]. The mechanism underlying anti-VEGF agents-induced subretinal fibrosis remains unclear. In previous studies, we found that bevacizumab (BEV) increased the expression of inflammatory mediators associated with fibrosis in human retinal pigment epithelial (ARPE-19) cells [7,8]. Epithelial-mesenchymal transition (EMT) of RPE cells plays an important role in the development of ocular fibrotic diseases after anti-VEGF treatment [9,10].

MicroRNAs (miRs) are a class of endogenous small RNAs of about 18-22 nucleotides in length that regulate gene expression and exert various biological functions such as proliferation, differentiation, apoptosis, immune function, and angiogenesis [11,12]. Up-or down-regulations of certain miRs are closely related to the occurrence and progression of various diseases and can be applied as molecular targets to diagnosis and treatment ocular diseases [13-16]. It has been reported that miR-21 plays a critical role in regulating fibrosis of various tissues through diverse pathways [17-19]. Usui-Ouchi A et al found that upregulation of miR-21 levels in the vitreous humor is associated with development of proliferative vitreoretinal disease by promoted cell proliferation and migration in RPE cells [20]. Many studies in other organs have shown that miR-21 is involved in the EMT of cells [21-24]. Snail is a zinc-finger transcription factor and one of the best-known functions of Snail is to regulate EMT during tumorigenesis and fibrosis. Li H et al determined that Snail involves in the TGFβ1-mediated EMT of RPE cells and overexpression of Snail in RPE cells
activated EMT [25,26]. Wang et al have demonstrated that miR-21 could stabilize Snail by
regulating the PTEN/Akt/GSK3β pathway in sepsis [27]. In current study, we aimed to
investigate the effect of miR-21 on BEV induced EMT in ARPE-19 cells and to search
potential molecular therapy targets for attenuating fibrosis after BEV treatment.

Methods

Cell culture and treatment

The ARPE-19 cells (ATCC, Rockefeller, Maryland, USA) were cultured in DMEM/F-12 medium
(Invitrogen, Carlsbad, CA, USA) supplemented with 10% fetal bovine serum (FBS, Gibco,
Life Technologies, Carlsbad, USA), 100 U/ml penicillin and 100 μg/ml streptomycin (Sigma-
Aldrich, St Louis, MO, USA) at 37°C in humidified air with 5% CO₂. ARPE-19 cells were
exposed to a clinical concentration (0.25 mg/ml) of BEV (Roche Diagnostics, GmbH,
Germany) for 2 days. In some experiments, 10 μM of SB431542 (Tocris Bioscience,
Minneapolis, Minnesota, USA) and 2 μM of SIS3 (Aladdin, Shanghai, China) were added in
the culture medium.

Cell transfection

The ARPE-19 cells divided into several groups: the negative control (NC) group (ARPE-19
cells were treated with BEV and transfected with negative control sequence of miR-21
inhibitor or mimic); miR-21 inhibitor group (ARPE-19 cells were transfected with 50 nM of
miR-21 inhibitor (RiboBio Biotechnology, Guangzhou, China) one day before BEV
treatment); miR-21 mimic group (ARPE-19 cells were transfected with 50 nM of miR-21
mimic (RiboBio Biotechnology) one day before BEV treatment).

qRT-PCR assay

The quantitative real-time polymerase chain reaction (qRT-PCR) assay was performed to
detect the expression of miR-21 in ARPE-19 cells. Total RNA was isolated using Trizol
(Invitrogen, Carlsbad, CA, USA) from ARPE-19 cells and the level of miR-21 was determined using specific primers (RiboBio Biotechnology, Guangzhou, China). U6 was used for normalization. qRT-PCR was performed using the Qiagen Rotor-Gene quantitative PCR system according to the manufacturer's protocol (Vazyme Biotech, Nanjing, China). Reaction conditions: pre-change for 10 seconds at 95°C, 5 seconds at 95°C, and 20 seconds at 60°C for 40 cycles. The expression level of the gene is represented by 2-ΔΔCt (Ct represents a cycle threshold).

**Western blot analysis**

Total protein was extracted from lysis of ARPE-19 cells in a radioimmunoprecipitation assay (RIPA) buffer containing a mixture of protease inhibitors and 50 μg of total protein per sample were loaded and separated on 10% SDS-PAGE, and then wet-transferred using PVDF membranes (Rugby WAR, UK). The membranes were blocked in 5% skimmed milk powder in TBST and incubated overnight with specific primary antibodies of E-cadherin (1:1000; Abcam), α-SMA (1:1000; Abcam), Snail (1:1000; Cell Signaling Technology, Trask Lane, Danvers, USA), TGFβ1 (1:1000; Cell Signaling Technology), Phospho-smad2/3 (1:1000; Cell Signaling Technology) and total-smad2/3 (1:1000; Cell Signaling Technology). On the second day, horseradish peroxidase-labeled secondary antibody (goat anti-rabbit IgG at a concentration of 1:2000, ZSGB-BIO, Beijing, China) was added dropwise for 1 hour at room temperature. After the end of the immunological reaction, the cells were illuminated and developed with a western blot chemiluminescence reagent (Invitrogen, Carlsbad, CA, USA). Images were captured using a western blot imaging system (Bio-rad ChemiDoc Touch, USA) and were analyzed using Image J version software (NIH, Bethesda, MD, USA).

**Statistical analysis**

Statistical analysis was performed using SPSS 19.0 software (SPSS Inc., Chicago, IL, USA),
and the data were expressed as mean ± standard deviation. The data between two groups were analyzed by unpaired t-test. One-way ANOVA test was used to determine the statistical difference among three groups. Values of p<0.05 were considered significant.

Results

**Bevacizumab causes EMT in ARPE-19 cells**

The effect of BEV on EMT in ARPE-19 cells was determined by detecting of an epithelial marker (E-cadherin) and a mesenchymal marker (α-smooth muscle actin, α-SMA). The western blot results showed 0.25 mg/ml of BEV treatment caused loss expression of E-cadherin (Fig 1A) and increased expression of α-SMA (Fig 1B) significantly indicating that BEV induced EMT in ARPE-19 cells under our experimental conditions.

**BEV-induced EMT were regulated by miR-21 in ARPE-19 cells**

The level of miR-21 in ARPE-19 cells were evaluated by qRT-PCR. The results showed that the expression of miR-21 in BEV treated ARPE-19 cells were up-regulated compared with the control group (1.02 ± 0.025 vs. 2.43 ± 0.345, P < 0.05) (Fig 2). To determine the role of miR-21 on regulating BEV-induced EMT, the expression level of miR-21 was decreased by transfected with miR-21 inhibitor and increased by transfected with miR-21 mimic when the cells were exposed to BEV. Western blot results showed that the E-cadherin expression in the miR-21 inhibitor group was obviously higher than that in the NC group and the α-SMA expression was significantly reduced in the miR-21 inhibitor group than that in the NC group (Fig 3 A and B). Conversely, the E-cadherin expression in the miR-21 mimic group was down-regulated significantly compared with the NC group and the α-SMA expression was up-regulated in the miR-21 mimic group than that in the NC group (Fig 3 C and D). These findings demonstrated the low expression of E-cadherin and high expression of α-SMA caused by BEV were reversed by decreasing miR-21 expression and enhanced by increasing miR-21 expression suggesting that miR-21 may play a critical role in regulating
BEV-induced EMT in ARPE-19 cells.

**miR-21 mediates BEV-induced Snail production in ARPE-19 cells**

Snail is a known mesenchymal marker, we examined whether miR-21 regulates BEV-induced EMT responses by modulating Snail production in ARPE-19 cells in the present studies. As expected, BEV enhanced the protein expression of Snail in ARPE-19 cells significantly (Fig 4A). Inhibition of miR-21 using miR-21 inhibitor suppressed the production of Snail enhanced by BEV (Fig 4B) and promotion of miR-21 using miR-21 mimic aggravated the expression of Snail (Fig 4C). The results indicated that miR-21 might promote BEV-induced EMT via mediating Snail production.

**TGFβ1/smad2/3 pathway involved in BEV-induced EMT in ARPE-19 cells**

In order to understand the mechanism of BEV promoting EMT, we detected the effect of BEV on TGFβ1/smad2/3 signaling pathway in our experimental system. We found that BEV up-regulated TGFβ1 (Fig 5A) and p-smad2/3 (Fig 5B) dramatically. TGFβ1 inhibitor SB431542 and smad3 inhibitor SIS3 were used to block TGFβ1/Smad2/3 pathway and the expression of E-cadherin, α-SMA and Snail were measured to further determine the role of TGFβ1/Smad2/3 signaling in BEV-induced EMT. As shown in Fig 5C, SB431542 and SIS3 increased the expression of E-cadherin, and decreased the expression of α-SMA and Snail in BEV-treated ARPE-19 cells.

**miR-21 regulated TGFβ1/smad2/3 signaling and inhibition of TGFβ1/smad2/3 signaling abrogated miR-21 over-expression induced EMT promotion**

Suppression of miR-21 by miR-21 inhibitor inhibited the promotion effects of TGFβ1 (Fig 6A) and p-smad2/3 (Fig 6B) caused by BEV. Moreover, over-expression of miR-21 by miR-21 mimic more enhanced the promotion of TGFβ1 (Fig 6C) and p-smad2/3 (Fig 6D) induced by BEV in ARPE-19 cells. We further blocked TGFβ1/Smad2/3 pathway to examine its role in regulating the EMT promotion effects mediated by miR-21. The reduced expression of E-
cadherin and the elevated promotion of α-SMA and Snail expression induced by miR-21 mimic were inhibited by SB431542 or SIS3 (Fig 6E). The above findings suggested that TGFβ1/Smad2/3 pathway played an important role in regulating the function of miR-21, blockage of TGFβ1/smad2/3 signaling abrogated miR-21 over-expression induced EMT promotion in ARPE-19 cells.

Discussion

Anti-VEGF agents such as BEV are widely used in the treatment of ocular neovascular disease. Fibrosis as an unfavorable effect caused by anti-VEGF therapy may seriously impair the visual prognosis [3,8,28]. EMT of RPE cells plays a critical role in the development of ocular fibrotic diseases [9,10]. In the present study, we demonstrated that BEV caused EMT in ARPE-19 cells accompanying with the upregulation of miR-21. The further analysis of miR-21 on BEV-induced EMT with miR-21 inhibitor and mimic showed that miR-21 played a key role in BEV-induced EMT in ARPE-19 cells by regulating Snail expression. Furthermore, the study found that miR-21 promoted BEV-induced EMT via TGFβ1/smad2/3 signaling.

MicroRNAs are small non-coding single stranded RNAs, which could be molecular targets for the diagnosis and treatment of diseases. Several microRNAs such as MicroRNA-148a and MicroRNA-124 have been reported associated with EMT of RPE cells [29-31]. We found that miR-21 was significantly higher in the vitreous fluid of patients with diabetic retinopathy, and it was positively correlated with the number of anti-VEGF drug injections, suggesting that anti-VEGF treatment can change the expression level of miR-21, and miR-21 may be involved in the occurrence of subretinal fibrosis after anti-VEGF treatment (data not shown). Previous studies have indicated that miR-21 is closely related to the occurrence of fibrosis in many organs, including the lung, heart, kidney and skin [17]. Usui-Ouchi A et al identified miR-21 as a candidate fibrotic miRNA with an important role
in the pathogenesis of proliferative vitreoretinal disease (PVD) [20]. As key cells that respond of anti-VEGF agents, RPE cells play an important role in the occurrence of retinal fibrosis. RPE cells participate in the formation of fibrosis mainly through epithelial-mesenchymal transition. Here, we first studied the potential role of miR-21 in BEV-induced EMT in vitro using ARPE-19 cells. We found that the expression of miR-21 in BEV-treated ARPE-19 cells was up-regulated significantly. Gain- and loss-of-function studies revealed that miR-21 positively regulated BEV-induced EMT by decreasing the expression of E-cadherin and increasing the expression of α-SMA. Many researches about the relationship of miR-21 and EMT in other tissues [21-23,32] are consistent with our results, which further prove our conclusion. However, miR-21-5p were downregulated in TGFβ2-induced EMT in human RPE cells [31].

Snail transcription factor has been implicated as an important regulator in EMT of RPE cells. The expression of E-cadherin, which plays a key role in maintaining the epithelial phenotype is mainly regulated by Snail. Snail represses the expression of E-cadherin at transcriptional level by binding to E-box consensus sequences in the E-cadherin promoter [25]. Snail positively regulates TGFβ1-induced EMT in human RPE cells; specific inhibition of Snail could significantly attenuate TGF-β1-induced EMT [25]. Over-expression of Snail could directly trigger EMT in ARPE-19 cells [26]. Previous study has demonstrated that miR-21 has the function of stabilizing Snail [27]. Snail is usually maintained at low levels in cells [33], while BEV treatment dramatically increased the expression of Snail in ARPE-19 cells. Enhanced miR-21 by miR-21 mimic increased the production of Snail and down-regulated miR-21 by miR-21 inhibitor decreased the production of Snail. These results suggesting that miR-21 could regulate Snail in ARPE-19 cells under BEV treatment conditions. Further detection of TGFβ1/smaded2/3 signaling revealed that BEV promoted TGFβ1 expression and smad2/3 phosphorylation, up or down-regulated of miR-21
enhanced or suppressed the activation of TGFβ1/smad2/3 signaling. TGFβ1 has been considered as a major regulator in EMT and fibrosis development. TGFβ1 could cause the phosphorylation of smad2 and smad3 proteins and phosphoactivated smad2/3 form a complex with smad4 that regulates numerous target genes. The transcriptional events of TGFβ1/smad2/3 subsequently regulate cell function by inducing growth arrest, apoptosis, cell migration, EMT, etc [34]. In this experiment, we found blockage of TGFβ1/smad2/3 signaling abrogated BEV caused EMT and abrogated miR-21 over-expression induced EMT promotion and Snail over-expression demonstrating the crucial role of TGFβ1/smad2/3 pathway in regulating the EMT promotion effects mediated by BEV and miR-21 in ARPE-19 cells. These findings are consistent with many previous studies in other tissues [35-39]. Several studies have reported that TGFβ1/smad2/3 signaling was involved in EMT process in RPE cells [40-42].

Conclusions

In conclusion, our findings demonstrated miR-21 regulated BEV-triggered EMT in RPE cells through up-regulating Snail expression via TGFβ1/smad2/3 signaling pathway. Inhibition of miR-21 could attenuate BEV-induced EMT. miR-21 might be a potential miRNA-based therapeutic target in reducing anti-VEGF agents-induced subretinal fibrosis.
