Dynamic Variations in Punicalagin and Related Metabolic Substances in Pomegranate Fruit and Leaves During Development Periods

Lijuan Feng, Yanlei Yin*, Xuemei Yang, Haixia Tang and Qiqing Jiao

Shandong Institute of Pomology, Tai’an, Shandong 271000, China

Pomegranate (Punica granatum L.) is a functional fruit that is abundant in bioactive substances. Punicalagin is an abundant and important phenolic compound in pomegranate, but the variation patterns and linkage of punicalagin and related synthetic bioactive substances during development are unclear. In this study, the dynamic variations in punicalagin and related synthetic bioactive substances were investigated in different parts of pomegranate during development phases. Punicalagin and related synthetic substances in the pomegranate pericarp, juice, seeds, and leaves were determined by high-performance liquid chromatography. Results revealed that punicalagin, gallic acid, shikimic acid, and total phenol contents, as well as DPPH radical scavenging activity, decreased gradually in the fruit, whereas pentagalloylglucose and 3-dehydroshikimic acid contents increased gradually. Seven substances yielded different variation patterns in the leaves. Ellagic acid content initially decreased and then increased in the fruit and leaves. Pentagalloylglucose was mainly detected in the leaves, while shikimic acid, 3-dehydroshikimic acid, punicalagin, gallic acid, and ellagic acid were mainly found in the pericarp. The highest punicalagin concentration was 156.735 mg·g⁻¹ in the TSH pericarp. Shikimic acid and 3-dehydroshikimic acid were closely related to gallic acid. Punicalagin was significantly positively correlated with gallic acid in the fruit, and significantly negatively correlated with pentagalloylglucose. Antioxidant activity and total phenol content were also closely correlated. Punicalagin and related substances presented different variation patterns in various pomegranate parts during development. Punicalagin was the most abundant phenolic compound in the pericarp, and this finding correlated significantly with gallic acid, ellagic acid, shikimic acid, 3-dehydroshikimic acid, and pentagalloylglucose in the fruit. The pomegranate pericarp contained abundant phenolic compounds and exhibited high antioxidant activity.

Key Words: antioxidant properties, bioactive substances, dynamic variation, pomegranate, punicalagin.

Introduction

Pomegranate (Punica granatum L.) is one of the oldest and most widely grown horticulture crops in several tropical and subtropical countries including India, Turkey, China, the United States, Spain, Italy, Chile, and South Africa (Fawole and Opara, 2013; Chater et al., 2018). Pomegranates are very rich sources of phenolic compounds that are mainly found in various parts such as the pericarp, juice, seeds, leaves, and flowers. For instance, pomegranate contains major phenolic compounds including ellagitannins, punicalagins, flavonoids, gallic acid, and ellagic acid (Singh et al., 2014; BenSaad et al., 2017). These pomegranate phenolic compounds have several health-promoting effects such as antioxidative, anti-inflammatory, antimicrobial, antidiabetic, and antitumor properties (Orgil et al., 2014; Modaeinama et al., 2015; Clementi et al., 2017).

Punicalagin is the most abundant and predominant ellagitannin found in pomegranate (Seeram et al., 2005; Landete, 2011). The biosynthetic pathway of other ellagitannins, such as tellimagrandin II and coruscin E, has been reported, but the biosynthetic pathway of punicalagin is poorly understood (Vermerris and Nicholson, 2006). Gallic acid, pentagalloylglucose, and ellagic acid are related to ellagitannin metabolism (Vermerris and Nicholson, 2006; Dewick, 2009).
Shikimic acid and 3-dehydroshikimic acid are closely related to gallic acid metabolism (Ossipov et al., 2003; Muir et al., 2011). Gallic acid is metabolized into penta-galloylgucose via a series of enzymatic reactions (Grundhöfer et al., 2001). Pentagalloylgucose is then transformed into ellagitannins such as tellimagrandin II and cornusuin E, which are precursors in ellagitannin metabolism (Niemetz and Gross, 2003; Dewick, 2009). Ellagic acid is a degradation product of ellagitannins such as tellimagrandin II and punicalagin (Dewick, 2009). Punicalagin belongs to the ellagitannin family, and its metabolism is similar to ellagitannin. Therefore, shikimic acid, 3-dehydroshikimic acid, gallic acid, pentagalloylgucose, and ellagic acid are possibly related to punicalagin metabolism (Qin et al., 2017) (Fig. 1).

Punicalagin in pomegranate has been isolated and identified (Fischer et al., 2011), and its content (Lu et al., 2008) has been evaluated. Punicalagin has several health benefits, including antioxidant, antiviral, anti-proliferation and anticancer properties, and has chemopreventive and chemotherapeutic effects against cervical cancer in humans through inhibition of the β-catenin signaling pathway (Clementi et al., 2017; Tang et al., 2017). Punicalagin inhibits lipopolysaccharide-induced memory impairment via anti-inflammatory and anti-amylogenic mechanisms through inhibition of NF-κB activation (Kim et al., 2017). However, the metabolic mechanism of punicalagin in pomegranate has not yet been investigated. Therefore, our research aimed to (i) investigate the dynamic variations and antioxidant properties of punicalagin and its related synthetic substances in pomegranate pericarp, juice, seeds, and leaves during development and (ii) identify the possible linkage between punicalagin and related synthetic bioactive substances in the fruit and leaves. This study provides a theoretical basis for the functional development of pomegranate, and can support the further development of the pomegranate industry.

**Materials and Methods**

**Sample preparation**

Two Chinese pomegranates, ‘Taishanhong (TSH)’ and ‘TaishanSanbaitian (TSSBT)’ were used as experimental materials. TSH has a red pericarp, red arils and good quality, and TSSBT has a white pericarp, white arils and excellent quality. Ten trees were randomly chosen from a pomegranate orchard located in Taian City, Shandong Province, China, where they were grown under homogeneous conditions. Fruits and functional leaves were picked at 10-day intervals from July 15 to October 2 (full maturity) in 2015–2017. The sampling dates were July 15(S1), July 25(S2), August 4(S3), August 14(S4), August 24(S5), September 3(S6), September 13(S7), September 23(S8), and October 2(S9), respectively. Samples of 20 representative fruits were collected from four tree orientations (east, west, south, and north). The samples were placed in a cooler and transported to a lab. The fruits were peeled manually with a peeler. The pomegranate arils were squeezed in two-layered muslin cloth to extract the juice completely. Fruit peels, seeds, juice, and leaves were lyophilized using an LGJ-10 freeze dryer (Songyuan-huaxing Company, Beijing, China) and then stored at −80°C in a refrigerator until analysis.

**Extraction of punicalagin, gallic acid and ellagic acid**

The extraction method for punicalagin, gallic acid, and ellagic acid was established by Schieber et al. (2001). Frozen peels, juices, seeds, and leaves were ground in liquid nitrogen by using a mortar and pestle. A tissue sample (1.0 g) was added to 10 mL of ultrapure water. The aqueous solution was adjusted to pH 7.0 and extracted with 10 mL of ethyl acetate to determine punicalagin. The extracts were shaken for 30 min on a shaking bed and centrifuged at 4,700 × g for 15 min at 4°C. The upper phase containing ester was separated, and the aqueous phase was extracted twice with ethyl acetate. The ester phase, which was neutral phenol, was combined, and the combined extracts were evaporated to dryness with an RE-52AA rotary evaporator (Shanghaiyiarong Biochemical Instrument Company, Shanghai, China). The residue was dissolved in metha-
nol (2 mL), membrane filtered (0.22 μm), and used for HPLC analysis. The aqueous phase was adjusted to pH 2.0 and extracted with the same method used to isolate gallic acid and ellagic acid.

**Extraction of shikimic acid and 3-dehydroshikimic acid**

The shikimic acid and 3-dehydroshikimic acid contents of the extracts were determined according to the method described by Zhou et al. (2010). A tissue sample (1.0 g) was added to 40 mL of ultrapure water in a covered conical flask. After ultrasonic treatment for 90 min at 60°C with a KQ2200E-type ultrasonic cleaner, the extracts were centrifuged at 7,500 × g for 15 min. The supernatant liquors were diluted with ultrapure water to 50 mL in a volumetric flask, filtered through a membrane (0.22 μm), and stored at −80°C in a refrigerator until HPLC determination.

**Extraction of pentagalloylglucose**

The extraction method for pentagalloylglucose was established by Xie et al. (2013). A tissue sample (0.5 g) was added to 40 mL of methanol in a conical flask, and then ultrasonically treated for 30 min at 37°C with a KQ2200E-type ultrasonic cleaner. The extracts were centrifuged at 7,500 × g for 20 min. The volume of the supernatant liquors was adjusted to 50 mL by adding methanol in a volumetric flask. The extracts were filtered with a 0.22 μm membrane and used for HPLC determination.

**HPLC–DAD analysis**

HPLC analysis was conducted using an Agilent 1260 series HPLC system (1260 quaternary pump VL, series DEABJ01988) coupled with a photodiode array detector (series DEAA01400) and an autosampler (series DEAAC23689), and operated with Agilent ChemStation. Separations were performed on a Zorbax SB-C18 column (150 mm × 4.6 mm ID, 5 μm). The chromatographic conditions of punicalagin and its related compounds were established by our research group (Feng et al., 2017). The mobile phases of punicalagin, gallic acid, and ellagic acid consisted of acetonitrile and glacial acetic acid (2%, v/v), at a ratio of 20:80 (v/v). The mobile phases of shikimic acid and 3-dehydroshikimic acid were composed of methanol and phosphoric acid (1%, v/v), at a ratio of 5:95 (v/v). The mobile phases of pentagalloylgucose were acetonitrile and 0.5% (v/v) phosphoric acid at a ratio of 20:80 (v/v).

The optimum absorption wavelength of punicalagin, gallic acid, and ellagic acid was 280 nm under the same conditions. The absorption wavelength of shikimic acid and 3-dehydroshikimic acid was 214 nm, and the absorption wavelength of pentagalloylgucose was 279 nm. The column temperature was set at 30°C. The flow rate of the mobile phase was 0.8 mL·min⁻¹. The injection volume for all samples was 10 μL. The regression equation, $R^2$, linear range, and LOD of punicalagin and related substances are shown in Table 1.

**Determination of total polyphenols concentration**

The Folin–Ciocalteu method with slight modifications was used to determine the total polyphenol concentration (Ainsworth and Gillespie, 2007). Gallic acid was used as the standard and distilled water was used as a blank. In brief, 1.0 mL of each diluted extract sample, in which 0.1 mL of extract sample was diluted to 10 mL by adding distilled water, punicalagin, gallic acid, and ellagic acid, was mixed with 1.0 mL of distilled water and 1.0 mL of Folin–Ciocalteu reagent and then 2 mL of sodium carbonate solution (10%) was added. Absorbance was read at 765 nm after 60 min of reaction at 30°C. Results were expressed as milligrams gallic acid equivalent per gram of pomegranate extract. Each extract sample was tested in triplicate.

**Determination of DPPH radical scavenging capacity**

DPPH radical scavenging capacity was determined according to the method described by Negi and Jayaprakasha (2003) with slight modifications. In brief, 2.0 mL of each diluted extract sample, in which 0.1 mL of the extract sample was diluted in 10 mL of distilled water, punicalagin, gallic acid, and ellagic acid, was mixed with 2.0 mL of DPPH–ethanolic solution. The diluted extract sample (2.0 mL) was mixed with ethanolic solution (2.0 mL). The absorbance at 517 nm was recorded after 10 min. An ethanol solution was used as a blank. In brief, 1.0 mL of each diluted extract sample, in which 0.1 mL of extract sample was diluted to 10 mL by adding distilled water, punicalagin, gallic acid, and ellagic acid, was mixed with 2.0 mL of DPPH–ethanolic solution. The diluted extract sample (2.0 mL) was mixed with ethanolic solution (2.0 mL). The absorbance at 517 nm was recorded after 10 min. An ethanol solution was used as a blank.

| Substance          | Regression equation | $R^2$ | Linear range (mg·L⁻¹) | LOD (mg·L⁻¹) |
|--------------------|---------------------|-------|-----------------------|--------------|
| α-Punicalagin      | $y=36924x-1245$     | 0.999 | 2.0–60                | 0.23         |
| β-Punicalagin      | $y=20475x-915$      | 0.999 | 2.0–60                | 0.21         |
| Gallic acid        | $y=54826x-3519$     | 0.999 | 1.5–40                | 0.20         |
| Ellagic acid       | $y=10518x-1382$     | 0.999 | 2.0–70                | 0.19         |
| Shikimic acid      | $y=58903x-22.3$     | 0.999 | 2.0–45                | 0.18         |
| 3-Dehydroshikimic acid | $y=39512x-50.55$  | 0.999 | 2.5–50                | 0.25         |
| Pentagalloylgucose | $y=34325x-95.66$    | 0.999 | 3.0–80                | 0.12         |

*y is the peak area; x refers to the concentration of each substance (mg·L⁻¹).
a blank.

Scavenging capacity (SC) was calculated by using the following equation: SC (%) = \(1 - \frac{(A_i - A_j)}{A_0}\) × 100, where \(A_i\) is the absorbance of the extract sample mixture and DPPH–ethanolic solution, \(A_j\) is the absorbance value of the extract sample mixture and ethanolic solution, and \(A_0\) is the absorbance value of the DPPH–ethanolic solution. Each extract sample was tested in triplicate.

Statistical analysis

Off-line Agilent ChemStation was used for HPLC data processing. SPSS version Rel.19.0 for Windows was used for statistical analysis. The experimental indexes value was the average value for 2015–2017. ANOVA was performed to determine the concentration difference in punicalagin and its related synthetic substances during development phases. Differences among means were considered significant at \(P < 0.05\) with Tukey’s honest significant difference test. Correlation coefficients were determined with Pearson’s correlation matrix method.

Results

Variations in punicalagin, gallic acid, and ellagic acid

The dynamic variations in punicalagin, gallic acid, and ellagic acid in different parts of two pomegranate cultivars are shown in Figure 2. The concentrations of punicalagin in the two cultivars showed similar variation patterns in the pericarp, juice, seeds, and leaves, and decreased gradually with fruit development. The peak value of punicalagin was detected in S1. This suggested that the punicalagin level was higher in the early development period and lower in the late development period. Compared with other periods, the punicalagin concentration of TSH showed a significant difference in the peel in S3, in juice in S1 and S2, and in seeds in S1 (Fig. 2A). There was a significant difference in the punicalagin concentration of TSSBT in juice in S5 (Fig. 2B). Significant differences were also found in the highest concentrations of punicalagin, gallic acid, and ellagic acid in the pericarp, juice, seeds, and leaves in S1.

The gallic acid concentrations of the two cultivars

![Graphs showing variations in punicalagin, gallic acid, and ellagic acid](image_url)

Fig. 2. Variations in punicalagin, gallic acid, and ellagic acid in different pomegranate parts during development phases. Data shown are the means of three replicates, and the vertical bar represents the standard error. * Significant difference at 0.05 levels compared to other samples in the same part in different development stages. ** Significant difference at 0.01 levels compared to other samples in the same part in different development stages.
decreased gradually in the pericarp, juice, and seeds, and the highest value was obtained in S1 (Fig. 2C, D). Gallic acid initially increased and subsequently decreased in the leaves, and its peak was observed in S4. Compared with other periods, the gallic acid concentration of TSH showed a significant difference in the peel from S1 to S4 and S7 to S9 (Fig. 2C). The difference in gallic acid in TSSBT peel was significant compared with that in other periods (Fig. 2D).

Conversely, the ellagic acid concentrations of the two cultivars initially decreased and then increased in the pericarp, juice, seeds, and leaves, and their peak values were observed in S1 and S9 (Fig. 2E, F). There was a significant difference in the ellagic acid concentrations in different parts of the two cultivars during development periods.

The concentration of punicalagin decreased in different parts in the following order: pericarp > juice > seeds > leaves during maturation. The punicalagin concentration of TSH ranged from 79.11 mg·g$^{-1}$ to 156.74 mg·g$^{-1}$ on October 2 in the pericarp, and there was 68.12–128.46 mg·g$^{-1}$ in the TSSBT pericarp. This indicated that the punicalagin concentration in the TSH pericarp was higher than that of TSSBT. The concentration of gallic acid likewise decreased in the following order: pericarp > leaves > juice > seeds during maturation. The concentration of ellagic acid also decreased in the following order: pericarp > juice > leaves > seeds during maturation.

**Variations in shikimic acid, 3-dehydroshikimic acid, and pentagalloylglucose**

In our study, the shikimic acid concentration of the two cultivars decreased gradually in the pericarp, juice, and seeds, and the peak value appeared in S1. The concentration of shikimic acid first increased and then decreased in the leaves, and the peak was observed in S3 (Fig. 3A, B). The 3-dehydroshikimic acid concentration of the two cultivars increased gradually during development (Fig. 3C, D). The concentration of 3-dehydroshikimic acid initially decreased and then increased in leaves, and the peaks were observed in S1 and S9.

Pentagalloylglucose showed a variation pattern simi-
lar to 3-dehydroshikimic acid, and the content of the former increased gradually in the pericarp, juice, and seeds during development (Fig. 3E, F). Pentagalloylglucose initially decreased and then increased in leaves, and the peaks were detected in S1 and S9.

Significant differences were found in the concentrations of shikimic acid, 3-dehydroshikimic acid, and pentagalloylglucose in different parts in the two cultivars. The concentration of shikimic acid decreased in the following order: pericarp > juice > leaves > seeds, except in S1 and S2. This result suggested that shikimic acid was mainly found in the pericarp. The concentration of 3-dehydroshikimic acid also decreased in the early development period (from S1 to S2): leaves > pericarp > juice > seeds. In the late development period (from S6 to S9), the concentration of 3-dehydroshikimic acid was reduced in the following order: pericarp > juice > seeds > leaves. This finding showed that 3-dehydroshikimic acid was mainly found in the leaves and pericarp. The concentration of pentagalloylglucose likewise decreased in the following order: leaves > pericarp > juice > seeds in different development stages.

Variations of total phenol concentration and DPPH radical scavenging activity

The total phenol concentration (Fig. 4A, B) and DPPH radical scavenging activity (Fig. 4C, D) of the two cultivars decreased gradually in the pericarp, juice, and seeds, and the peak was detected in S1. The variation pattern of total phenol content and DPPH radical scavenging activity in the leaves were different from those in the fruit. The total phenol content and DPPH radical scavenging activity in the leaves initially increased and then decreased during development. The peaks of the total phenol content and DPPH radical scavenging activity in the leaves were observed in S4.

Significant differences were found in the total phenol concentration and DPPH radical scavenging activity. The total phenol concentration and DPPH radical scavenging activity decreased in the following order: pericarp > juice > leaves > seeds. The highest concentrations of total phenols in the TSH and TSSBT pericarps were 15.65 times and 19.88 times that in the seeds, respectively. This finding suggests that pomegranate pericarp contains high amounts of phenolic compounds and elicits strong antioxidant activities (Tzulker et al., 2007; Aviram et al., 2008).

Correlation analysis

The relationship between punicalagin and related substances was investigated through correlation analysis in the two cultivars (Table 2–5). These substances were similarly correlated in the pericarp, juice, seeds, and leaves. Punicalagin was significantly and positively correlated with gallic acid in fruit, but was not correlated with gallic acid in leaves. Gallic acid was significantly and positively correlated with ellagic acid in the fruit. Punicalagin and ellagic acid were significantly and positively correlated with shikimic acid, but significantly and negatively correlated with 3-dehydroshikimic acid, in the fruit. Pentagalloylglucose
### Table 2. Correlation analysis of different indexes in the fruit peel of two pomegranate cultivars.

| Cultivars | Index       | Punicalagin | Gallic acid | Ellagic acid | Shikimic acid | 3-dehydroshikimic acid | Pentagalloylglucose | Total phenols | DPPH |
|-----------|-------------|-------------|-------------|--------------|---------------|------------------------|--------------------|--------------|-------|
| TSH       | Punicalagin | 1           |             |              |               |                        |                    |              |       |
|           | Gallic acid | 0.958**     | 1           |              |               |                        |                    |              |       |
|           | Ellagic acid| 0.924**     | 0.928**     | 1            |               |                        |                    |              |       |
|           | Shikimic acid| 0.981**   | 0.990**     | 0.956**      | 1             |                        |                    |              |       |
|           | 3-dehydroshikimic acid | −0.960** | −0.992**  | −0.930**  | −0.992**  | 1                        |                    |              |       |
|           | Pentagalloylglucose | −0.871** | −0.955**  | −0.930**  | −0.995**  | 0.992**                  | 1                    |              |       |
|           | Total phenols | 0.985**     | 0.986**     | 0.957**    | 0.997**    | −0.985**                | −0.993**            | 1             |       |
|           | DPPH         | 0.871**     | 0.961**     | 0.839**    | 0.933**    | −0.965**                | −0.943**            | 0.921**       | 1     |
| TSSBT     | Punicalagin | 1           |             |              |               |                        |                    |              |       |
|           | Gallic acid | 0.993**     | 1           |              |               |                        |                    |              |       |
|           | Ellagic acid| 0.928**     | 0.951**     | 1            |               |                        |                    |              |       |
|           | Shikimic acid| 0.988**   | 0.979**     | 0.904**     | 1             |                        |                    |              |       |
|           | 3-dehydroshikimic acid | −0.992** | −0.997**  | −0.960**  | −0.979**  | 1                        |                    |              |       |
|           | Pentagalloylglucose | −0.983** | −0.995**  | −0.964**  | −0.975**  | 0.997**                 | 1                    |              |       |
|           | Total phenols | 0.983**     | 0.983**     | 0.952**    | 0.985**    | −0.992**                | −0.991**            | 1             |       |
|           | DPPH         | 0.990**     | 0.984**     | 0.890**    | 0.974**    | −0.976**                | −0.968**            | 0.956**       | 1     |

* Results show a significant correlation at 0.05 levels, ** Results show a significant correlation at 0.01 levels.

### Table 3. Correlation analysis of different indexes in the fruit juice of two pomegranate cultivars.

| Cultivars | Index       | Punicalagin | Gallic acid | Ellagic acid | Shikimic acid | 3-dehydroshikimic acid | Pentagalloylglucose | Total phenols | DPPH |
|-----------|-------------|-------------|-------------|--------------|---------------|------------------------|--------------------|--------------|-------|
| TSH       | Punicalagin | 1           |             |              |               |                        |                    |              |       |
|           | Gallic acid | 0.939**     | 1           |              |               |                        |                    |              |       |

* Results show a significant correlation at 0.05 levels, ** Results show a significant correlation at 0.01 levels.
was also significantly negatively correlated with ellagic acid in the fruit.

Gallic acid was significantly and positively correlated with shikimic acid in the fruit and leaves, but was negatively correlated with 3-dehydroshikimic acid. Shikimic acid was significantly and negatively correlated with 3-dehydroshikimic acid, and was significantly and positively correlated with total phenol content and DPPH radical scavenging activity. 3-Dehydroshikimic acid was also significantly and positively correlated with pentagalloylglucose. Pentagalloylglucose was significantly and negatively correlated with punicalagin and gallic acid in the fruit. Total phenol content was significantly and positively correlated with DPPH radical scavenging activity. Previous studies also revealed high correlations between antioxidant activity and total phenol content (Tzulker et al., 2007; Zhao et al., 2008).

**Discussion**

**Variations in punicalagin, gallic acid, and ellagic acid**

Punicalagin, gallic acid, and ellagic acid are major phenolic compounds in pomegranate. The punicalagin content decreased in different parts during maturation and this observation is consistent with that reported in Israeli pomegranate pericarp (Shwartz et al., 2009). Ellagic acid content decreased in the early development period, and this finding was in accordance with that in strawberry (Williner et al., 2003). Ellagic acid content increased in the late development period, and this was consistent with the finding in muscadine grapes (Lee and Talcott, 2004).

In our study, the punicalagin concentration of the two cultivars was highest in the pericarp. The punicalagin concentration in the pericarp in the mature stage was 40–122 mg·g⁻¹ (Lu et al., 2008). High punicalagin contents (5.48–36.68 mg·g⁻¹ of TSH, 3.26–29.35 mg·g⁻¹ of TSSBT) were also found in pomegranate juice. In previous studies, punicalagin contents were 4–565 mg·L⁻¹ (Fischer et al., 2011) and 20–1350 mg·L⁻¹ (Gil et al., 2000) in pomegranate juice. The lowest punicalagin concentration was detected in the leaves, and this finding indicated that punicalagin was not the most important phenolic compound in leaves. High punicalagin contents in the pericarp and juice have been extensively investigated. Punicalagin is also considered to be a promising multifunctional compound because of its remarkable pharmacological attributes, health-beneficial properties, bioavailability, and nontoxic nature (Kulkarni et al., 2007).

In four pomegranate parts, the concentrations of punicalagin, gallic acid, and ellagic acid significantly differed. The highest concentrations of punicalagin, gallic acid, and ellagic acid were mainly found in the pericarp. This finding suggests that phenolic compound concentrations are higher in pomegranate pericarp than in other parts (Fischer et al., 2011). The highest punicalagin concentration in the two cultivars was higher than those of gallic acid and ellagic acid in the peel. This result is in agreement with previous studies (Tzulker et al., 2007), which revealed that punicalagin was the most abundant phenolic compound in pomegranate pericarp.

**Variations in shikimic acid, 3-Dehydroshikimic acid, and pentagalloylglucose**

Shikimic acid is an essential compound in synthesis pathways for aromatic amino acids, alkaloids, and phenolic compounds (Gurib-Fakim, 2006). Shikimic acid is also a key intermediate for the synthesis of the neuraminidase inhibitor oseltamivir (Tamiflu), an antiviral drug (Cui et al., 2014). 3-Dehydroshikimic acid is an intermediate in the catabolism of shikimic acid via the β-ketoadipate pathway (Chang et al., 2003). 3-Dehydroshikimic acid is produced from shikimic acid via the shikimic acid pathway (Ghosh et al., 2012). Gallic acid synthesized from 3-dehydroshikimic acid has been detected in birch leaves (Ossipov et al., 2003). Our results showed that the variation pattern in shikimic acid was similar to that of gallic acid, and unlike that of 3-dehydroshikimic acid. Correlation analysis showed that gallic acid was significantly and positively correlated with shikimic acid in the fruit and leaves, but was negatively correlated with 3-dehydroshikimic acid. Shikimic acid was significantly and negatively correlated with 3-dehydroshikimic acid. These findings suggest that shikimic acid and 3-dehydroshikimic acid are closely related to gallic acid metabolism in pomegranate (Muir et al., 2011).

Pentagalloylglucose, a naturally occurring hydrolysable tannin and an active compound present in many traditional medicinal herbs, exhibit multiple biological activities (Pei et al., 2011; Kim et al., 2014). Pentagalloylglucose in the two cultivars initially decreased and then increased in the leaves. The large amount of pentagalloylglucose in pomegranate leaves was consistent with the experimental result in *Tellima grandiflora* (Niemetz and Gross, 2003) and *Rhus typhina* (Niemetz and Gross, 2001).

Gallic acid is the starting material for hydrolysable tannin synthesis (Ossipov et al., 2003), and can generate pentagalloylglucose (Grandhöfer et al., 2001). Punicalagin was significantly and positively correlated with gallic acid in the fruit. Pentagalloylglucose was significantly and negatively correlated with punicalagin and gallic acid in the fruit. Therefore, gallic acid and pentagalloylglucose are metabolized into punicalagin mainly in pomegranate fruit (Tzulker et al., 2007).

**Variations in total phenols and DPPH radical scavenging activity**

Total phenols protect fruits from plant diseases and pests during early development, although only low amounts of phenols are required during late development (Shwartz et al., 2009). The total phenol concentra-
tion of the two cultivars decreased gradually during development. This result is consistent with that observed in guava fruit (Bashir and Abu-Goukh, 2003). The decrease in total phenols causes a reduction in fruit astringency, which is a desirable sensory attribute of pomegranate (Kulkarni and Aradhya, 2005). The decrease in total phenols is attributed to polyphenol oxidation by polyphenol oxidase during fruit ripening (Fawole and Opara, 2013).

The antioxidant activity in different pomegranate parts has been quantified in terms of its radical scavenging potential (Kulkarni and Aradhya, 2005). DPPH radical scavenging activity was significantly and positively correlated with total phenol. Previous studies also revealed high correlations between antioxidant activity and total phenol content (Tzulker et al., 2007; Zhao et al., 2008). The antioxidant activity of pomegranate peel was the highest, followed by the juice, and was the lowest in seeds. This result is supported by a study in Turkey pomegranate (Orak et al., 2012) that revealed the levels of antioxidants in different pomegranate parts. The difference in the antioxidant activity of the peel, juice, leaves and seeds may be ascribed to their different phenolic compositions (Singh et al., 2002). As a result, pomegranate peel could be further exploited and used in health supplements.

Punicalagin, ellagic acid, gallic acid, shikimic acid, 3-dehydroshikimic acid, ellagic acid, and pentagalloylglucose are bioactive compounds in pomegranate. Total phenol content and DPPH radical scavenging activity were significantly and positively correlated with punicalagin, gallic acid, shikimic acid, ellagic acid in the fruit and leaves. These results implied that the concentrations of punicalagin, gallic acid, shikimic acid, and ellagic acid were highly correlated with total phenol content and antioxidant activity. 3-Dehydroshikimic acid and pentagalloylglucose were significantly and negatively correlated with total phenol content and DPPH radical scavenging activity in the fruit. This phenomenon may be influenced by development stage and different pomegranate parts.

The seasonal variations in punicalagin and related synthetic compounds during development phases in different pomegranate parts were investigated. Further studies should be performed to understand the metabolism of punicalagin in pomegranate. The relationship of punicalagin and related regulatory enzymes should also be further explored. Punicalagin regulatory enzyme genes should be cloned, and their expression levels during development should be analyzed at the molecular level.

Conclusions
Punicalagin and related substances showed different variation patterns in various pomegranate parts during development. Punicalagin was the most abundant phenolic compound in the pericarp; it was significantly positively correlated with gallic acid and shikimic acid in the fruit, and significantly negatively correlated with pentagalloylglucose and 3-dehydroshikimic acid. Pomegranate pericarp contained abundant phenolic compounds and exhibited strong antioxidant activity. Our study revealed the variation patterns and tissue differences of punicalagin content and related substances in pomegranate. This could provide a theoretical basis for the development and utilization of different pomegranate parts.
