Abstract

Background: Body image is a perception of our physical appearance. Weight misperception in adolescent lead to body dissatisfaction and obesity in adolescent. Gender also plays a role in adolescent obesity and body image. Obese adolescents have greater risk of non-communicable diseases than adolescents with normal weight. therefore, this research aims to discover body image and gender influence on adolescent obesity.

Method: This study is an observational design with cross sectional approach. The study was conducted in November 2019 at SMK Negeri 9 Surakarta. The subjects were 57 sophomore that were chosen randomly with simple random sampling. Body image and obesity were measured using MBSRQ-AS questionnaire, BMI for Age Charts and waist circumference. Data was processed by independent T-test, fisher exact test, logistic regression test with significance value p <0.05.

Results: There is a significant difference in body image scores between obese and non-obese group (p = 0.006) and male students scored higher in every aspect of body image than female students. A significant relationship was found between body image and obesity (p=0.045), and gender with obesity (p = 0.009).

Conclusion: There is a significant relationship between body image and gender with obesity in adolescents and body image scores differ significantly between obese and non-obese group and between male and female students.

Keywords: body image, obesity, gender, adolescents
Obesity defined as an abnormal accumulation of excess fat in adipose tissue that can lead to other health problems and also known as one of the health problems in the world. Adolescents obesity is a global concern because of its impacts on health and high rate incidence in the world. In 2016, WHO reported that over 340 million children and adolescents aged 5-19 were obese. Adolescent’s obesity has a greater risk of developing non-communicable diseases compared to normal weight counterparts and often have psychological and social problems such as self-confidence, misperception on body image, depression, anxiety and discrimination.

Based on Erik Erikson’s Physicosocial Development theory, adolescence is the stage of finding an identity. This makes adolescents is a crucial period in forming body image. Their perception of the ideal body can be influenced by gender, media, ethics, and social interaction. Ideal body perception between female and male is different. Female tends to want a thin body but male likes bulky body more. Media is responsible for the thin body as an ideal body image. Thin ideal body stigma causes obese adolescents to tend to feel dissatisfied with their body or called body dissatisfaction. This weight misperception can cause body dissatisfaction that induces maladaptive eating behavior in adolescents. The prevalence of weight misperception also increases along with the prevalence of adolescent obesity.

This study aims to analyze the relationship between body image and gender with obesity in adolescents. This research is also useful to increase knowledge related to body image and obesity and can be used as a source to educate teenagers in evaluating their bodies and using a body image approach to promote adolescents obesity prevention.

METHODS

Study design
This study is an observational analytic design with a cross sectional approach.

Study subjects
The study takes place at SMK Negeri 9 Surakarta which is under Banyuanyar Public Health Center territory work area in November 2019. Subjects of this study were sophomore in multimedia and visual communication design class that were chosen randomly by simple random sampling. The sample size was calculated using the Lemeshow formula and 55 samples were obtained. This study also had an ethical clearance from Faculty of Medicine, Universitas Sebelas Maret, number 331/UN27.06/KEPK/EC/2019.

Study variables
The dependent variable was obesity. In this study, obesity was measured by using WHO’s BMI for age chart and measuring tape. The measuring tape was used for measuring waist circumference. Measurement of waist circumference and BMI is needed in this study to increase the sensitivity and specificity. The cut-offs for obesity in this study were >+2SD and/or >86.45 cm for male’s waist circumference and >76.50 cm for female’s waist circumference. Adolescent does not have universal cut-offs. Therefore, waist circumference’s cut-offs is based on research that was conducted in Indonesia by Mulyasari and Pontang. Independent variable was body image and gender. Body image is an individual’s perception of their physical appearance based on self observation and other’s opinions. MBSRQ-AS was used to assess body image. There were five aspects of body image in MBSRQ-AS, appearance evaluation, appearance orientation, overweight preoccupation, body area satisfication, and self-classified weight. Self-classified weight will not be assessed. In this section, the question is a categorical question that can’t be scored. This questionnaire consists of appearance orientation, appearance evaluation, overweight preoccupation, body area satisfication, and self-classified weight. Self-classified weight will not be assessed. In this section, the question is a categorical question that can’t be scored. Data analysis
Firstly data were analyzed with Kolmogorov-smirnov normality test and Homogeneity test. The data was normal and homogenous. To determine the relationship between 2 variables, the independence T-test, Mann Whitney, and fisher’s exact test were used. Independence T-test and Mann Whitney are used to analyze body image and obesity, while fisher’s exact test is used to analyze gender and obesity. To evaluate the two independent variables on influencing the dependent variable this study used logistic regression. In logistic regression, two
variables can be included simultaneously to get an adjusted odds ratio. All of these tests was run by SPSS 24 Software for Windows.

RESULTS

Characteristics subject from this study were categorized into several variables, like age, gender, physical activity, and parents socioeconomic conditions. Based on gender and age, there were 40 male students and 17 female students with age ranges from 16 to 18 years old (Table 1). According to table 1, total of 35 students had moderate physical activity, and based on the distribution of parents’ socioeconomic conditions, 59.6% were reported to have low income category and based on their obesity status, 13 students belong to obese groups and 44 in non-obese groups.

According to a univariate analysis of body image, all of the subjects in this study were reported to have a positive body image (≥2,50). But there were significant body image score differences between male and female students where male student scores higher than the female students (Table 2). This correlation was tested using an independent T-test.

Table 1. Subject’s characteristic

| Characteristics        | N   | %   |
|------------------------|-----|-----|
| Gender                 |     |     |
| Male                   | 40  | 70.2|
| Female                 | 17  | 29.8|
| Age                    |     |     |
| 16 years old           | 39  | 68.4|
| 17 years old           | 17  | 29.8|
| 18 years old           | 1   | 1.8 |
| Physical Activity      |     |     |
| Low                    | 22  | 38.6|
| Moderate               | 35  | 61.4|
| Parents Income         |     |     |
| Low                    | 34  | 59.6|
| High                   | 23  | 40.4|
| Obesity                |     |     |
| Obese                  | 13  | 22.8|
| Non Obese              | 44  | 77.2|

Independent T-test was used to evaluate the correlations between body image and obesity and obtained p value = 0.006 which means there are significant differences in body image mean scores between the obese and non-obese groups (Table 4). The obese group has a smaller mean body image score than non-obese group.

Table 2. Gender, obesity and body image scores

| Gender      | Male | Female | Min | Max  | Mean | 95% CI | P    | Upp-er | Low-er |
|-------------|------|--------|-----|------|------|--------|------|--------|--------|
| Obesity     |      |        |     |      |      |        |      |        |        |
| Non Obese   | 2,74 | 4,19   | 3,22| 0,03 | 0,39 | 0,03   |      |        |        |
| Obese       | 2,71 | 3,39   | 2,94| -0,475 | -0,083 | 0,006 |      |        |        |

In addition to body image, gender is also associated with obesity. Based on the fisher’s exact test results showed the value of p = 0.001 (Table 5). Therefore, it can be concluded that gender variables have a significant relationship with obesity.

Table 3. Correlation between body image scores and obesity

| Gender     | Male | Female | P   |
|------------|------|--------|-----|
| Obesity    |      |        |     |
| Non Obese | 4    | 9      | 0.001|
| Obese      | 36   | 8      |     |

This study assessed four body image aspects in MBSRQ-AS questionnaire. There are appearance evaluation, appearance orientation, overweight preoccupation, and body area statisfication. Appearance evaluation shows how individuals see their overall appearance. Based on table 6, the subject of this study have a high score in this section. Meanwhile, appearance orientation will show the subject’s concern about their body through the effort that they made to change and it was reported that female students and the obese groups have a bigger tendency to do something about their appearance than male students and non-obese group.

Table 4. Independent T-Test and Mann Whitney results of body image aspect scores with obesity and gender

| Body image | Obesity | Non obese | P   | Gender | Male | Female | P   |
|------------|---------|-----------|-----|--------|------|--------|-----|
| Appearance |         |           |     |        |      |        |     |
| evaluative | 3,3     | 3,38      | 0.58| 3,38   | 3,30 | 0.61   |     |
| Appearance | 2.73    | 2.95      | 0.09| 2.94   | 2.83 | 0.38   |     |
| orientation|         |           |     |        |      |        |     |
| Overweight | 2.67    | 3.34      | **0.01**| 3.30 | 2.98 | 0.21   |     |
| preoccupation|       |           |     |        |      |        |     |
| Body area  | 3.03    | 3.42      | 0.074| 3.46   | 3.05 | **0.03**|     |
| statisfication*| | | | | | |     |

*Analyzed with Mann Whitney

Overweight preoccupation is individual’s fear becoming fat and body area statisfication is a statisfication of particular body parts. Table 6 showed
that overweight preoccupation has a significant relationship with obesity which means the obese group is reported to have greater weight gain anxiety. Furthermore, the body area statisfication aspect has significant relationship with gender. It can be concluded that male and female have a different body parts preference.

Body image, gender, and obesity were analyzed using multivariate logistic regression analysis. The logistic regression analysis obtained p value = 0.045 for body image and 0.009 for gender. body image’s adjusted odds ratio is 0.035, which means higher body image scores will reduce the possibility of getting obese. From table 7, gender’s adjusted odds ratio is 7.43 and it shows that female students have a higher risk to become obese than male students.

Table 5. Association between Body Image, Gender and Obesity

| Variables   | Odds Ratio (OR) | CI 95% Upper | CI 95% Lower | P     |
|-------------|-----------------|--------------|--------------|-------|
| Body Image  | 0.035           | 0.001        | 0.928        | 0.045 |
| Gender      |                 |              |              |       |
| Male (0)    | 7.143           | 1.617        | 31.554       | 0.009 |
| Female (1)  |                 |              |              |       |

DISCUSSIONS

Body image scores and gender have a significant correlation with obesity. An adjusted odds ratio of body image score is 0.035, which means respondent with low body image scores has a higher obesity risk than respondent with high body image scores. Based on gender’s adjusted odds ratio, it is known that female respondents are at risk 7.143 times becoming obese. Body image can influence obesity through weight misperception. This misperception is divided into underestimation and overestimation. Underestimation is found in an obese who does not consider themselves obese. Overestimation can usually be found in someone who has normal weight but feeling fat. Overestimation and underestimation of body weight can cause inappropriate eating behavior and cause obesity. Negative body image or dissatisfaction with the body can cause inappropriate eating behavior. Another factor that can affect obesity in this study is gender. Female was reported to have a higher risk of becoming obese because of the increase of estrogen hormone in female.

Body image scores differ between male and female respondents. These differences can be caused by the fact that men tend to be more confident and have better self-concept (a person’s perception of their appearance, abilities, and role) compared to women. A study by Jain & Tiwari found that the boy’s perception about the ideal self not only came from a muscular body but also the ability to solve problems and good manners. Men’s physical changes at puberty such as the formation of muscles and enlargement of shoulder width is in accordance with the ideal idea of the masculine body. Therefore, adolescent boys tend to be more satisfied with their bodies. Another alike results were found in research conducted in Indonesia that men tend to have higher body image scores compared to women.

In spite of having different body image score, all respondent in this study is classified as body image positive. Factors that influencing body image scores in this study are age, gender, and intrapersonal interaction. Most respondent in this study is at age 16 and body dissatisfaction towards body increases with age. Body dissatisfaction most often appears at the age of 18 years old to 25 years old and tends to persist or worsen with age. Based on the section self-classified weight in MBSRQ-AS questionnaire, the majority of respondents (38.6%) felt that their bodies were considered thin by others. This shows that the respondent’s environment did not give negative comments on his appearance. Interpersonal relationships with family and peers can affect body image. Comments from family and peers about appearance is one of the factors that can prevent negative body image in adolescent girls. Majority student in SMKN 9 Surakarta is a male student. Male tends to have a positive body image when they were a teenager. This uneven ratio between male and female student influence peer interaction and eventually prevent female student having body image negative.

In conclusion, it can be concluded that student with low body image score and female more likely to become obese and obese student tends to have a low body image score. An intervention strategy to prevent adolescent obesity may also be based on body image, especially by using the overweight preoccupation aspect.

Acknowledgments

The author would like expressed a gratitude and highest appreciation to Ari Natalia Probandari, dr., MPH, Ph.D, Vitri Widyaningsih, dr., MS and Heni Hastuti, dr., MPH for their advice and direction from the research plan until the completion of the writing of this research. The author would also like to thank SMK N 9 Surakarta for their participation.
