A new family of infinitely braided Thompson’s groups

Julio Aroca and Maríá Cumplido

May 20, 2020

Abstract

We present a generalization of the Dehornoy-Brin braided Thompson group $BV_2$ that uses recursive braids. Our new groups are denoted by $BV_{n,r}(H)$, for all $n \geq 2, r \geq 1$ and $H \leq B_n$, where $B_n$ is the braid group on $n$ strands. We give a new approach to deal with braided Thompson groups by using strand diagrams. We show that $BV_{n,r}(H)$ is finitely generated if $H$ is finitely generated.

Key words. Thompson groups, braid groups, strand diagrams, rewriting systems.

1 Introduction

The aim of this article is to define new families of Thompson-like groups based on the ones defined independently by Dehornoy (2006) and Brin (2006, 2007). Thompson-like groups are based on the notion of cloning system, firstly defined by Witzel & Zaremsky (2018). A cloning system on a family of groups $(G_n)_{n \in \mathbb{N}}$ is a set of axioms and maps acting on $G_n$ which allows to get a group $F(G_n)$, called the generalized Thompson group for the cloning system or Thompson-like group (see Zaremsky, 2018 and Witzel & Zaremsky, 2018 for more details). The motivation for defining these new families is that Thompson-like groups have proven to be new examples of interesting groups. Richard Thompson used the celebrated groups $F, T$ and $V$ in 1965 to construct finitely presented groups with unsolvable word problems (see Cannon et al., 1996, Higman, 1974 for the definitions of $F, T$ and $V$). Other interesting families which come from cloning systems are branch groups (Bartholdi et al., 2003) and self-similar groups (L. Bartholdi & Nekrashevych, 2003) which contain the first examples of groups of intermediate growth, like Grigorchuk’s group (Grigorchuk, 1980).

We will focus our attention on the Thompson-like groups coming from a cloning system on the family of groups $(B_n)_{n \in \mathbb{N}}$, the Artin braid groups (Artin, 1947). In (Brin, 2006, 2007), Brin uses this family to define a braided Thompson group $V_{br}$, that we denote on our article as $BV_2$; one of the first examples of Thompson-like groups with no torsion, apart from the family of Higman-Thompson groups $F_n$, where $n \geq 2$ (Higman, 1974). The usual way to understand $BV_2$ is as the group of affine and orientation-preserving isotopies from the binary Cantor set $C_2$ to itself, using finite covers consisting of dyadic intervals. Brin also defines a monoid $\overline{BV}_2$, and proves that both groups are finitely presented by using a purely algebraic argument based on Zappa-Szép products.

Using a similar approach, we present in this article new families of Thompson-like groups based on the previous ones. In the first place, we give the natural generalization of $BV_2$ by using $r$ copies of $n$-ary Cantor sets $C_n$ for all $r \geq 1$ and $n \geq 2$, obtaining all braided Thompson-like versions $BV_{n,r}$ of the well-known Higman-Thompson groups $V_{n,r}$, defined on (Higman, 1974). Next, we apply a recursive definition of braid (inspired on the definition of self-similar group) to construct a family of infinitely braided Thompson-like groups $BV_{n,r}(H)$, where $H \leq B_n$. 

2000 Mathematics Subject Classification. 20F65, 20F05, 20F36.

Key words. Thompson groups, braid groups, strand diagrams, rewriting systems.
\[ B_n \] Moreover, it is also possible to define the monoid versions of \( BV_{n,r} \) and \( BV_{n,r}(H) \): \( \widehat{BV}_n \) and \( \widehat{BV}_n(H) \). Note that all these families can be compiled on only two: \( BV_{n,r}(H) \) and \( \widehat{BV}_n(H) \), as we can consider \( H = Id \).

The first part of the article is devoted to prove that all these families are groups. For this aim we use a generalization of the Belk-Matucci theory of strand diagrams (Aroca, 2018, Belk & Matucci, 2014) and rewriting systems (Newman, 1942) to give a bijection between elements of \( BV_{n,r}(H) \) and braided strand diagrams, a family of oriented graphs with labelled vertices (see Section 3.2 for all the details). As it is easier to prove that braided strand diagrams form a group, we obtain the desired result. Finally, we prove the main theorem of this article:

**Theorem 1.** If \( H \leq B_n \) is finitely generated, the groups \( BV_{n,r}(H) \) and \( \widehat{BV}_n(H) \) are finitely generated for every \( r \geq 1, n \geq 2 \).

For this purpose, we use a different and simpler approach than the one used by Brin. With the help of Higman-Thompson’s groups \( F_{n,r} \) and the properties of braids and diagrams, we generalize the idea of Higman (1974) to give explicit generators for all these groups (see Theorem 24, Section 4.1.1 and Section 4.3).

To resume, in Section 2 we define \( BV_{n,r}(H) \) and \( \widehat{BV}_n(H) \) for every \( r \geq 1, n \geq 2 \) and \( H \leq B_n \). In Section 3 we prove they are in fact, groups, by defining braided strand diagrams and applying the theory of rewriting systems to them. Finally, the aim of Section 4 is to prove are finitely generated (if \( H \) is finitely generated). We give explicit set of generators when \( H = Id, B_n \) and when \( H \) is a standard parabolic subgroup of \( B_n \).

2 The infinitely braided groups \( BV_n(H) \)

In this section we define the main objects of this article: the braided versions of Higman-Thompson’s groups \( V_{n,r}, BV_{n,r} \); and its generalization, the family of infinitely braided groups \( BV_{n,r}(H) \). The fact that these are, indeed, groups is proved in Section 3.

2.1 Descriptions of \( V_{n,r}, BV_{n,r} \) and \( \widehat{BV}_n \)

Let \( C_n \) be the \( n \)-adic Cantor set, which is constructed inductively as follows: \( C_n^0 \) corresponds to first subdividing \( C_n^0 = [0,1] \) into \( 2n - 1 \) intervals of equal length, numbered \( 1, \ldots, 2n - 1 \) from left to right, and then taking collection of odd-numbered subintervals. We will renumber these intervals from left to right and denote them \( C_n^1, \ldots, C_n^l \). Next, \( C_n^2 \) is obtained from \( C_n^1 \) by applying the same procedure to each interval \( C_n^1 \) to obtain \( C_n^2 \) to obtain \( C_n^3 \). We recursively define every \( C_n^j \) with \( j > 1 \) and its intervals. Let \( C_n \) be the intersection of all \( C_n^j \). The elements of the Thompson’s group \( V_n \) are defined using covers of \( C_n \) by pairwise disjoint intervals of the form \( C_n^1 \) chosen from any \( C_n^j \). For any pair of covers \( C \) and \( C' \) with the same number of intervals, we define an affine and orientation preserving map from the elements of \( C \) to the elements of \( C' \). Then we restrict the map to \( C_n \). This restriction is a homeomorphism of \( C_n \). Finally, we define \( V_n \) as the set of all maps of this kind, which turns to be a group under composition.

The elements of \( V_n \) are coded by pairs of finite full \( n \)-ary trees together with a bijection \( \tau \) between their leaves. An example of such a pair is depicted on Figure 1, where the left (resp. the right) tree indicates how the first (resp. the second) cover is split. These trees are respectively called domain tree \( T \) and range tree \( T' \). Therefore, any element \( v \in V_n \) is represented as a triple \( (T, \tau, T') \). Notice that this representative is not unique. A well known subgroup of \( V_n \), that
will be used in the last section, is $F_n$, consisting of all elements represented by triples $(T, \tau, T')$ where $\tau$ is trivial.

The set of leaves of all possible $n$-ary trees is in bijection with the set of finite words on the alphabet $A_n = \{0, \ldots, n - 1\}$, denoted by $A_n^*$. The word assigned to each leaf depends on the path taken from the root to reach the leaf. For example, observe that in Figure 1 the set of leaves of the first tree is $\{00, 01, 020, 021, 022, 1, 2\}$. This labelling induces a natural order on the set of leaves of a tree. By abuse of notation, we will say that a word in $A_n^*$ is its represented leaf.

Let $v \in V_n$ be represented by a tree pair $(T, \tau, T')$ such that $T$ and $T'$ have $l$ leaves. Note that there are two numbers assigned on each leaf: one of them is the coordinate of the leaf, that is, a finite word on the alphabet $\{0, \ldots, n - 1\}$. The other one is a number in $\{1, \ldots, l\}$ depending on the bijection $\tau$.

**Definition 2.** Let $T$ be finite full $n$-ary tree. We define a caret as a subtree of $T$ consisting on a set of vertices of the form $\{w, w0, w1, \ldots, w(n-1)\}$ and the set of edges linking $w$ with $wi$ for all $i \in \{0, \ldots, n-1\}$, for any finite word $w \in A_n^*$. We say that a caret is final if its set of vertices is also a set of leaves of $T$. We represent a caret by using its set of vertices.

As example, in Figure 1 the set of vertices $\{00, 01, 02\}$ of $T$ is a caret, and $\{020, 021, 022\}$ of $T$ is a final caret.

**Definition 3.** Let $T$ be a full finite $n$-ary tree. Let $w \in A_n^*$ be a leaf of $T$. We denote by $T[w]$ the tree obtained from $T$ by appending a final caret to $w$. Similarly, we define $T[c]^{-1}$ as the tree obtained from $T$ by removing a specific final caret $c = \{w0, \ldots, w(n-1)\}$ from it. We say that $T[w]$ (resp. $T[c]^{-1}$) is an expansion (resp. reduction) of $T$.

Keep in mind that, in a composition of expansions $T[w][w']$, $w'$ must always be a leaf of $T[w]$, although it does not need to be a leaf of $T$.

There exist infinitely many coverings which define the same element of $V_n$. Let $v = (T, \tau, T')$ be a homeomorphism of $C_n$ where a cover $c \in C$ is mapped to a cover $c' \in C'$. We can consider the subdivision of both $c$ and $c'$ into $n$ pieces $c_1, \ldots, c_n$ and $c'_1, \ldots, c'_n$ such that the affine map takes $c_i$ to $c'_i$ for all $i \in \{1, \ldots, n\}$. The corresponding tree-pair representative of the subdivided coverings leads to the same element $v$, previously defined in terms of $C$ and $C'$. In terms of trees, we add a final caret on the leaves $w$ and $w'$ representing the intervals $c$ and $c'$ respectively. Thus we obtain a new triple $v = (T[w], \tau', T'[w'])$ where $\tau'$ is the corresponding bijection including the new set of leaves.

We say that a tree-pair representative of an element is reduced if the number of covers of both $C$ and $C'$ (that is, the number of leaves of $T$ and $T'$) is minimal. A simple way to distinguish non-reduced elements is by checking if there exists a final caret $\{w0, w1, \ldots, w(n-1)\}$ which is mapped to another final caret $\{w'0, w'1, \ldots, w'(n-1)\}$ such that $wi$ is mapped to $w'i$ for every $i \in \{0, \ldots, n-1\}$.

Finally, the way to compose elements of $V_n$ is as follows: given two elements $v = (T, \tau, T')$ and $w = (T'', \tau'', T''')$ the composition is the element $vw = (T, \tau \tau', T''')$. Note that the range tree of $v$ and the domain tree of $w$ must be equal. If not, it is possible to expand the trees of both $v$ and $w$ until we get tree-pair representatives which can be composed.

In a similar way, we can consider $r$ copies of $C_n$ instead of only one, obtaining the group $V_{n,r}$. In that case, elements are represented as a pair of forests of $r$ finite full $n$-ary trees together with a bijection $\tau$ between their leaves. See (Cannon et al., 1996, Higman, 1974) for an introduction on these groups.
The previous description of \( V_n \) can be easily extended to obtain the braided Thompson’s groups \( BV_n \). Braided Thompson’s group \( BV_2 \) was introduced in (Brin, 2006, 2007) and (Dehornoy, 2006). As before, given any pair of covers \( C \) and \( C' \) of \( \mathcal{C}_n \) with the same number \( m \) of elements, we embed them in \( \{\mathbb{R}, 1\} \) and \( \{\mathbb{R}, 0\} \) respectively. Then, we define an orientation-preserving isotopy with compact support from the elements of \( C \) to the elements of \( C' \). In this case, the isotopy is represented by a braid \( \beta \) with \( m \) strands.

**Definition 4.** A *braid* is a collection of \( m \) disjoint paths in a cylinder connecting \( m \) points of its upper disk to \( m \) points of its lower disk and running monotonically in the vertical direction (see Figure 2). Two braids \( \beta, \beta' \) are equivalent if we can continuously deform \( \beta \) into \( \beta' \) without intersecting the paths. The equivalence classes of these objects (that will be called braids by an abuse of notation) are the elements of the *braid group* with \( m \) strands, \( B_m \), introduced in (Artin, 1947), which is presented as follows:

\[
B_m = \{\sigma_1, \ldots, \sigma_{m-1} | \sigma_i \sigma_j = \sigma_j \sigma_i \text{ if } |i - j| > 1, \sigma_i \sigma_j \sigma_i = \sigma_j \sigma_i \sigma_j \text{ if } |i - j| = 1.\}
\]

Here \( \sigma_i \) (resp. \( \sigma_i^{-1} \)) is the braid in which the strands in the \( i \)-th position passes over (resp. under) the strand in the \((i + 1)\)-th position. The set of \( \sigma_i \)'s is called the set of *Artin generators*.

A representative of an element \( v \in BV_n \) is a pair of finite full \( n \)-ary trees together with a braid \( \beta \) between their leaves, that is, \( v = (T, \beta, T') \). This triple is called *braided tree-pair*. The composition of these elements works as before. In order to better understand braided tree-pairs, we will use *braided diagrams* in which the range tree is pictured upside down below the domain tree, as pictured in Figure 2. These diagrams will be thoroughly used in this paper.

On a similar manner, by considering a finite number \( r \) of copies of \( \mathcal{C}_n \) and using the same definition as above, we get the group \( BV_{n,r} \).

The group \( \hat{BV}_n \) is built by embedding a countable number of copies of \( \mathcal{C}_n \), one on each interval \( \{[2i, 2i + 1], 1\} \) and \( \{[2i, 2i + 1], 0\} \) of \( \{\mathbb{R}, 1\} \) and \( \{\mathbb{R}, 0\} \) respectively. Consider two infinite covers \( C \) and \( C' \) such that the intervals are pairwise disjoint, as before, and all but finitely many of them are of the form \( \{[2i, 2i + 1], 1\} \) for \( C \) (resp. of the form \( \{[2i, 2i + 1], 0\} \) for \( C' \)). Finally, we map \( C \) to \( C' \) by an isotopy of \( \mathbb{R}^2 \), such that the images of the chosen intervals are parallel to the \( x \)-axis. Since the number of intervals is infinite, the isotopy could be a “shift” taking place for large values of \( x \). We impose that a shift must be done by an isotopy of the form

\[
(x, y) \rightarrow (x + td(1 - |y|), y)
\]

outside a compact, for \( |y| < 1 \), \( x > K \) for some positive constant \( K \); and by the identity otherwise. The integer \( d \) is the total amount of shift and \( t \) is the parameter of the isotopy, see (Brin, 2007). An example of such an element is depicted on Figure 3.
The proof of the fact that $BV_2$ and $\hat{BV}_2$ are groups can be found in (Brin, 2007). In Section 3, we will prove the same for our groups, as well as for the ones defined hereunder.

2.2 Descriptions of $BV_n(H)$ and $\hat{BV}_n(H)$

Let $H$ be a subgroup of the group of braids on $n$ strands $B_n$. The aim of this paper is to define new groups $BV_n(H)$ as a generalization of $BV_n$.

Let $C$ and $C'$ be two covers of $\mathfrak{C}_n$ with the same number of elements. Let $c \in C$, $c' \in C'$, and $h \in H \leq B_n$. A recursive braid of type $h$ between $c$ and $c'$ is a braid with infinitely many strands obtained by the following process: Replace $c$ and $c'$ by two subcovers $c_1, \ldots, c_n$ and $c'_1, \ldots, c'_n$ respectively, such that $h$ is an isotopy from $c_i$ to $c'_j$, (that is, $c_1, \ldots, c_n$ and $c'_1, \ldots, c'_n$ are braided by $h$). We repeat this process on every $c_i$ and $c'_j$ by subdividing them and applying $h$ again, and so on. Note that the composition of two recursive braids is again a recursive braid. In Figure 4, we can see graphically how to construct a recursive braid.

The group $BV_n(H)$ is the group of elements in $BV_n$ together with (possibly) recursive braids between covers of $\mathfrak{C}_n$. The way to represent an element $v \in BV_n(H)$ is as a triple $(T, \beta, T') \in BV_n$ together with a set $\lambda = \{h_i\}_{i=1}^m, h_i \in H \leq B_n$, where $m$ is the number of
leaves of both $T$ and $T'$. This set corresponds to the set of recursive braids on the $m$ strands of $\beta$. Each label indicates that there is a recursive braid of type $h_i$ between the $\beta(i)^{-1}$-th and $i$-th intervals linked by the corresponding strand of $\beta$. Therefore, we write $v = (T, \beta, \lambda, T')$. As before, there are infinitely many tree pair representations of the same element $v \in BV_n(H)$. In this case, final carets are mapped by elements of $H$: if some $c \in C$ is mapped to $c' \in C'$ with a recursive braid $h$, then the same isotopy maps the subcovering $c_i$ to $h(c_i) = c'_j(h)$ with a recursive braid $h$ for all $i \in \{1, \ldots, n\}$, where $j$ is the permutation on $n$ elements induced by $h$. In terms of tree-pair representations, $v$ maps a final caret to another one following the rules of $h$. Finally, note that elements of $BV_n$ can be expressed in terms of recursive braids, where $\lambda = \{\text{Id, \ldots, Id}\}$. Therefore, $BV_n = BV_n(\text{Id})$.

The group $\hat{BV}_n(H)$ is defined in the same way as $\hat{BV}_n$, by adding recursive braids. Similarly, if we consider a finite number $r$ of copies of $C_n$, we obtain $BV_{n,r}(H)$.

3 Braided diagrams and rewriting systems

In this section we prove that all the previously defined groups are in fact groups. In order to do that, we use a generalization of the theory of strand diagrams (Aroca, 2018, Belk & Matucci, 2014) and rewriting systems (Newman, 1942). This section is heavily inspired on the aforementioned work.

3.1 Basics about graphs

Consider a directed graph $\Gamma$. Let $V(\Gamma)$ be its set of (possibly labelled) vertices, and let $E(\Gamma) = \{e_1, e_2, \ldots, e_s\} \subset V(\Gamma) \times V(\Gamma)$ be the set of oriented edges, which have the form $e = (v, v')$ or $(v', v)$ depending on the orientation. An oriented path is a sequence of oriented edges $\{e_1, \ldots, e_t\} = \{(v_{i(1)}, v_{j(1)}), \ldots, (v_{i(t)}, v_{j(t)})\}$ such that $v_{j(k)} = v_{i(k+1)} \forall k \in \{1, \ldots, t-1\}$. If $v_{j(t)} = v_{i(1)}$, we have an oriented loop.

Definition 5. The degree of a vertex $v \in V(\Gamma)$ is the number of edges which have $v$ as endpoint, that is, those which have the form $(v, v')$ or $(v', v)$ for some $v' \in V(\Gamma)$.

Definition 6. A vertex $v$ is a source (resp. a sink) for a finite set of directed edges if they have $v$ as starting point (resp. ending point). A vertex $v$ is a main source (resp. a main sink) if it is a source (resp. a sink) of degree one.

Let $n \geq 2$. A split (resp. a merge) is a vertex $v$ of degree $n + 1$ which is a sink for one edge and a source for the others (resp. a source for one edge and a sink for the others). A white vertex $v^h$ is a vertex of degree 2 with a label $h \in H \leq B_n$. 

Figure 4: An example of recursive braid where $h = \sigma_1$. 
Definition 7. We say that \( \Gamma \) is **acyclic** if the graph has no oriented loops. From now on, \( \Gamma \) will be a directed acyclic graph.

Definition 8. A **pitchfork graph** is a graph whose vertices are only main sources, main sinks, white vertices, splits or merges for a fixed \( n \geq 2 \).

### 3.2 Braided diagrams

Let \( g \in BV_n(H) \) for some \( n \geq 2 \), \( H \leq B_n \) and \((T, \beta, \lambda, T')\) a braided tree-pair representative of \( g \). We recall that we can construct a braided diagram representation \( \Gamma' \) from an element \((T, \beta, T')\) of \( BV_n \) by picturing \( T' \) upside down below \( T \) and joining the leaves of both trees with the braid \( \beta \) (see again Figure 2). The aim if this subsection is to construct a well-defined braided diagram for \( g \).

Notice that \( \Gamma' \) may not be planar, but 3-dimensional. However, we can consider the obvious planar projection, depicted in Figure 2, that will be called, by abuse of notation, braided diagram.

Definition 9. We say that an oriented path of an acyclic graph is a **strand** if it only contains white vertices (excluding its endpoints).

Definition 10. A **braided diagram** is a planar projection \( \Gamma := p(\Gamma') \) of a finite directed acyclic pitchfork graph \( \Gamma' \) satisfying the following properties:

- Two vertices of \( \Gamma' \) never have the same image;
- No vertex is mapped onto an edge that it is not an endpoint of;
- The images of the edges of \( \Gamma' \) intersect in a finite set of points;
- The image of a strand cannot intersect itself.

The set of edge intersections that are not endpoints is the **set of crossings** \( C(\Gamma) \) of \( \Gamma \).

To distinguish isomorphic planar graphs with different crossings, we impose a rotation and a crossing system:

Definition 11. Let \( \Gamma \) be a braided diagram. A **rotation system** of \( \Gamma \) is a map \( \rho_{\Gamma} : E(\Gamma) \rightarrow \{0, \ldots, n\}^2 \) which gives an order to every edge of \( \Gamma \) around its endpoints as follows:

1. A counter-clockwise order to the directed edges of a split \( v \), where the 0-th edge is the edge which has \( v \) as sink.
2. A clockwise order to the directed edges of a merge \( v \), where the 0-th edge is the edge which has \( v \) as source.
3. A 0 to the edge which has a \( \sigma \)-vertex \( v \) as sink, and a 1 to the one which has \( v \) as source.

Definition 12. Let \( \Gamma \) be a braided diagram. A **crossing system** of \( \Gamma \) is a map \( \kappa_{\Gamma} : C(\Gamma) \rightarrow \{1, -1\} \) which gives a label to every crossing of \( \Gamma \). Geometrically, the crossings are depicted as in Figure 5.

Observe that \( \rho_{\Gamma} \) and \( \kappa_{\Gamma} \) completely determine the crossings of \( \Gamma \) and will represent the Artin generators composing a braid and their inverses. From now on, we will always consider that a braided diagram is endowed with a crossing and a rotation system.
Remark 13. Note that these systems provide a natural injection $f : \Gamma \cup C(\Gamma) \to \mathbb{R}^3$. By abuse of notation, we will denote $f(\Gamma \cup C(\Gamma))$ by $f(\Gamma)$. $\Gamma$ will be called a natural projection of $f(\Gamma)$.

Definition 14. Two braided diagrams $\Gamma_1$ and $\Gamma_2$ are equal if it exists an isomorphism $\phi : \Gamma_1 \to \Gamma_2$ such that:

1. $\phi(\rho_{\Gamma_1}) = \rho_{\Gamma_2}$,
2. $\phi(\kappa_{\Gamma_1}) = \kappa_{\Gamma_2}$, and
3. $\phi(v^h) = \phi(v)^h$, $\forall v \in V(\Gamma_1)$.

for every white vertex $v^h$.

It is possible to compose two braided diagrams $\Gamma'$ and $\Gamma''$ if the number of main sinks of $\Gamma'$ is equal to the number of main sources of $\Gamma''$. We then identify from left to right the main sinks of $\Gamma'$ with the main sources of $\Gamma''$ without creating any new crossing. The composition is again a braided diagram.

We now explain how to construct the braided diagram for an element $g \in BV_n(H)$, with tree-pair representative $(T, \beta, \lambda, T')$. Take the braided diagram of $(T, \beta, T')$ and then append to the $\beta(i)$-th leaf of $T$ the corresponding white vertex $v^h_i$. Next, append to the roots of both $T$ and $T'$ an edge and a vertex. Give the orientation from the vertex appended in $T$ to the leaves of $T$, from the leaves of $T$ to the leaves of $T'$ and finally from the leaves of $T'$ to the appended vertex of $T'$. The resulting directed acyclic pitchfork graph is the braided diagram of $g$. The process is similar for elements of $BV_{n,r}(H)$ and $\hat{BV}_n(H)$, but using forests instead of trees. Note that not all braided diagrams are obtained as a consequence of this process.

3.3 Rewriting systems and confluence

As said on the beginning of this section, we use the theory of rewriting systems (Newman, 1942) in order to prove that there exists a bijection between equivalence classes of braided diagrams and elements of $BV_n(H)$.

Definition 15. Let $\Gamma'$ be a finite directed acyclic pitchfork graph. Suppose that $\Gamma'$ has a collection of strands $S$ that has a neighbourhood isotopic to a cylinder which does not contain other edges. If, up to isotopy, this cylinder defines a braid $\alpha$, we say that $S$ is a sub-braid $\alpha$ of $\Gamma'$. For example, in Figure 2, the collection of the second and third strands of $\beta$ defines a trivial sub-braid.

Definition 16. Let $\Gamma' = f(\Gamma)$ be the natural injection of a braided diagram $\Gamma$ in $\mathbb{R}^3$. We define the following moves on $\Gamma$:

1. Consider a split $v_1$ and a merge $v_2$ of $\Gamma$ (and $\Gamma'$). Suppose that $\Gamma'$ has a sub-braid $h$ on $n$ strands connecting every $i$-th edge of $v_1$ with the $h(i)$-th edge of $v_2$. Also suppose that each strand of $h$ contains a (possibly empty) sequence of white vertices $\{v^{h_1}, \ldots, v^{h_t(i)}\}$ with $h_1 \circ \cdots \circ h_{t(i)} = h$, where each $t(i)$ depends on the strand.
Take the connected subgraphs $\Gamma_0$ of $\Gamma$ and $\Gamma'_0$ of $\Gamma'$ formed by $v_1$, $v_2$, $h$, the edges starting at $v_1$ and the edges arriving at $v_2$. Replace a neighbourhood of $\Gamma'_0$ by the neighbourhood of a single strand $\Gamma''_0$ containing a white vertex $v^h$ if $h \neq Id$; or a single strand with no white vertices, if $h = Id$. Let $\Gamma''$ be the new pitchfork graph. A 1-move replaces $\Gamma$ by a natural projection $p(\Gamma'')$ such that $p(\Gamma'' \setminus \Gamma''_0) = \Gamma \setminus \Gamma_0$. See Figure 6.

(2) Consider a merge $v_1$ and a split $v_2$ of $\Gamma$ (and $\Gamma'$). Suppose that $v_1$ and $v_2$ are connected by a strand $d$. Let $\{v^{h_1}, \ldots, v^{h_t}\}$ be a (possibly empty) sequence of white vertices on this strand with $h_1 \circ \cdots \circ h_t = h$.

Take the connected subgraphs $\Gamma_0$ of $\Gamma$ and $\Gamma'_0$ of $\Gamma'$ formed by $v_1$, $v_2$ and $d$. Replace $\Gamma'_0$ with the neighbourhood of the subgraph $\Gamma''_0$ obtained by adding a white vertex $v^h$ to every strand of $h$. This braid connects the $i$-th edge of $v_1$ with the $h(i)$-th edge of $v_2$, for all $i \in \{1, \ldots, n\}$. If $h = Id$, then we replace the neighbourhood of $\Gamma_0$ with the neighbourhood of $n$ edges connecting the $i$-th edge of $v_1$ and the $i$-th edge of $v_2$, with no crossings between them. Let $\Gamma''$ be the new pitchfork graph. A 2-move replaces $\Gamma$ by a natural projection $p(\Gamma'')$ such that $p(\Gamma'' \setminus \Gamma''_0) = \Gamma \setminus \Gamma_0$. See Figure 6.

Figure 6: Examples of 1-moves and 2-moves, where $h_1 \circ h_2 \circ \cdots \circ h_n = h$.

(3) Let $\Gamma_0$ be the subgraph of $\Gamma$ consisting of a crossing between two edges, such that one of them contains a white vertex. Then a 3-move moves the white vertex along the crossing, as Figure 7 shows.

(4) Let $\Gamma_0$ be the subgraph of $\Gamma$ consisting of one edge whose endpoints are two white vertices $v^{h_1}$ and $v^{h_2}$. A 4-move replaces the neighbourhood of $\Gamma_0$ with the neighbourhood of a strand containing a single white vertex $v^{h_2 \circ h_1}$. If $h_2 \circ h_1 = Id$, it replaces the neighbourhood of $\Gamma_0$ with a strand with no white vertices. See Figure 7.

(5) Suppose that in $\Gamma$ we have a crossing between two strands such that one of ends on a split. Then a 5-move pushes the crossing along the split, such that the strand without the split crosses the $n$ strands of the split as in Figure 8. The same occurs for the symmetric case involving two strands and one merge.

(6) Let $\Gamma_0$ be the neighbourhood of the subgraph of $\Gamma$ consisting of an edge $e$ whose endpoints are a merge and a white vertex $v^h$, where $e$ is the 0-th edge of the merge. Consider $\Gamma_1$, ...
obtained from $\Gamma_0$ by performing the inverse of a type 1-move on $e$. Let $\Gamma_2$ be obtained from $\Gamma_1$ by performing a 2-move on the merge and the new split created by the previous reduction. A 6-move replaces $\Gamma_0$ with $\Gamma_2$ (see Figure 8). The symmetric case (a split whose 0-th edge has a white vertex as endpoint) is analogously treated. There are several cases contained here, as the inverse of a 1-move is not unique.

![Figure 8: Examples of 5-moves and 6-moves.](image)

**Definition 17.** For two braided diagrams $\Gamma, \Gamma'$, we say that $\Gamma'$ is a *reduction* of $\Gamma$ if there exists a sequence of moves which takes $\Gamma$ to $\Gamma'$. Two braided diagrams are *equivalent* if one is a reduction of the other.

**Definition 18.** A braided diagram is *reduced* if no moves can be performed on it.

We construct a directed graph $R$ from the set of all braided diagrams as follows: the vertex set of $R$ consists of the set of all braided diagrams. The vertices are called *states*. We have an oriented edge from a state $s$ to a state $s'$ if we obtain $s'$ from $s$ by performing a move. The graph $R$ is called a *rewriting system*.

**Definition 19.** A rewriting system $R$ is *terminating* if every oriented path of $R$ has finite length. A state $s$ is *reduced* if no oriented paths start from $s$.

Note that if a rewriting system is terminating, then every state has a reduced form.
Definition 20. We say that a rewriting system is *locally confluent* if for all triples of states $s_0, s_1, s_2$ such that $s_1$ and $s_2$ are reductions of $s_0$, there exists a state $s_3$ which is a reduction of both $s_1$ and $s_2$.

Proposition 21. Every braided diagram is equivalent to a unique reduced braided diagram.

*Proof.* As it is explained in (Newman, 1942), we only need to show that the rewriting system of braided diagrams is terminating and locally confluent.

Firstly, we claim that the rewriting system of a braided diagram is terminating. Let $s$ be a state representing a braided diagram, and consider a path starting from it. This path cannot be infinite as:

- The number of 1-moves and 2-moves in the path is finite, as there is a finite number of splits and merges on $s$. 1 and 2-moves reduce them, whereas the other moves do not increase it.
- The number of 5-moves and 6-moves in the path is finite, as there is a finite number of crossings followed by splits, merges followed by crossings, merges followed by white vertices or white vertices followed by splits. The other moves do not increase these numbers.
- Finally, the number of 3-moves and 4-moves in the path is finite, as there is a finite number of white vertices and white vertices followed by crossings. In this case, these numbers can be increased by performing 5-moves and 6-moves, but they can be performed a finite number of times, as we have seen.

Note that the previous facts are true because there are not oriented loops on any braided diagram, by definition. Therefore, the process of reducing is finite, so the rewriting system is terminating.

On the other hand, it is easy to check the locally confluence for all moves, that is, if we perform two different moves to the same braided diagram, there exists a braided diagram which is a reduction of both. For this purpose, it is enough to check all possibilities: given a fixed braided diagram $\Gamma$, let $\Gamma'$ (resp. $\Gamma''$) be the braided diagram obtained from $\Gamma$ by performing one $i$-move (resp. one $j$-move). One needs to prove that there exists a braided diagram $\Gamma'''$ which is a reduction of both $\Gamma'$ and $\Gamma''$, for all $i, j \in \{1, \ldots, 6\}$. This is a laborious exercise left to the reader.

Corollary 22. There is a bijection between classes of equivalent braided diagrams and classes of equivalent elements of $BV_n(H)$.

*Proof.* We only need to prove that there is a bijection between reduced braided diagrams and reduced elements of $BV_n(H)$, as performing reductions and expansions of an element in $BV_n(H)$ corresponds to performing 1-moves and their inverses on the corresponding braided diagrams.

On the one hand, it is easy to see that a reduced element of $BV_n$ produces a reduced braided diagram when doing the construction described at the beginning of this section. On the other hand, given a reduced braided diagram, we obtain the corresponding reduced element of $BV_n(H)$ by taking into account the following facts: every oriented path from a main source to a main sink has the following form:

$$v_{m_{so}} \rightarrow v_{s_1} \rightarrow \cdots \rightarrow v_s \rightarrow v^h \rightarrow v_{m_1} \rightarrow \cdots \rightarrow v_{m_j} \rightarrow v_{m_{si}}$$

where $v_{m_{so}}$ (resp. $v_{m_{si}}$) is the main source (resp. the main sink), $v_{s_1}, \ldots, v_s$ (resp. $v_{m_1}, \ldots, v_{m_j}$) are splits (resp. merges) and $v^h$ is a white vertex.
• If there were a merge followed by a split we could perform a 2-move.

• If there were a white vertex before a split or after a merge, then we could perform a 6-move.

• If there were more than one white vertices on an oriented path, then we could perform a 4-move.

• Regarding the crossings, note that all strands must cross after the set of splits and before the set of white vertices. Otherwise, we could perform a 5-move and a 3-move respectively.

Finally, consider making two cuts on every oriented path of the braided diagram as follows: one cut between the last split and before any crossing of the corresponding strand; and the second cut after the last crossing of the strand and before the white vertex (if exists). The result is a division of the braided diagram into three pieces. The first one is the domain tree $T$, the second one the braid $\beta$ and the third one the range tree $T'$ with a set of labels $\lambda$ on its leaves. That is the tree-pair representation of the element.

Note that this bijection turns to be a homomorphism of groups: composing two elements of $BV_n(H)$ corresponds to composing their corresponding braided diagrams by appending an edge between the main sink of the former and the main source of the latter. Performing a 1-move corresponds on a braided diagram corresponds to performing a reduction on the corresponding element of $BV_n(H)$. 2-moves are used in order to compose braided diagrams, and they do not change the equivalence class of the composition, as the reader can check. The same argument can be applied to 3-moves and 5-moves. Finally, 4-moves allow us to compose recursive braids, and 6-moves do not properly appear on a composition of braided diagrams, but they are needed in order to obtain locally confluence on the rewriting systems.

Therefore, we have that $\bar{BV}_n(H)$ and $BV_{n,r}(H)$ are groups for every $n, r \geq 2$ and $H \leq B_n$, as the definitions of moves and all proofs given in this section do not depend on the number of main sources or main sinks of the braided diagrams.

4 Finite generation

In this section we show that the groups $BV_n(H)$ are finitely generated for every $n \geq 2$ and $H \leq B_n$. The proof is inspired by the one of (Higman, 1974, Chapter 4) for $V_n$, based on the depth of the elements; and it is different from the one used in (Brin, 2006, 2007) for the braided Thompson group $BV_2$.

The forthcoming proofs can seem very technical at a first sight, but they are very intuitive when one draws the corresponding braided diagrams. We have pictured the diagrams with the details that we believe can be more difficult to understand by only reading. However, before going ahead, we advise to have in mind a clear picture of how the braided diagram of a tree-pair looks like.

Definition 23. We say that a tree $T$ has depth $d \geq 1$ if it contains exactly $d$ different carets. The depth of an element $v = (T, \beta, \lambda, T') \in BV_n(H)$ is the depth of both $T$ and $T'$.

For simplicity, we will sometimes refer to an element $v \in BV_n(H)$ as one of its tree-pair representations $(T, \beta, \lambda, T')$. We want to prove the following theorem.

Theorem 24. Let $R$ be the $n$-ary tree of depth 1 and let $R' := R[1]$ if $n = 2$ and $R' := R[2]$ otherwise. Then $BV_n(B_n)$, for $n > 1$ can be generated using the $2n$ following elements:
• The $n$ generators of $F_n$ (Brown, 1987), that is, the elements \( \langle R[n-1], Id, \overrightarrow{Id}, R[i] \rangle \), for $i = 0, \ldots, n-2$ and \( \langle R[n-1][(n-1)(n-1)], Id, \overrightarrow{Id}, R[n-1][(n-1)0] \rangle \),

• the element \( \langle R', \sigma_{2n-2}, \overrightarrow{Id}, R' \rangle \), and

• the $n-1$ elements \( \langle R, Id, \{ \sigma_j, Id, \ldots, Id \}, R \rangle \), for $j = 1, \ldots, n-1$.

Figure 9: The six generators of $BV_3(B_3)$.

We depict on Figure 9 the six generators of $BV_3(B_3)$. As we will see in Section 4.1.1, we can adapt this theorem for each $H \leq B_n$.

4.1 Proof of Theorem 24

Our strategy uses a special type of braid, called ribbon. The following definition is a particular case of the ribbons defined in (Fenn et al., 1996). We say that a braid $\beta$ is positive if it can be written by using only positive powers of the Artin generators. Moreover, we say that a braid $\beta$ is simple if it is positive and every pair of strands crosses at most once.

Definition 25. Consider $T$ and $T'$ to be two finite full $n$-ary trees with the same number $l$ of leaves. Let $c$ and $c'$ be final carets of $T$ and $T'$ respectively. Let $R$ be the set of all simple braids $\beta \in B_l$ such that the natural injection in $R^3$ of the braided diagram of $\langle T, \beta, T' \rangle$ contains a trivial sub-braid connecting the of $c$ to the leaves of $c'$. We define the ribbon $r$ connecting $c$ to $c'$ as the braid in $R$ having minimal length (as a word with respect to the positive Artin generators).

We include here Figure 10 in order to help the reader. A ribbon is called like that because the neighbourhood of the trivial sub-braid connecting the carets can be seen as a ‘ribbon’ or a ‘tube’ that the other strands cannot touch. This allows us to reduce a braided diagram associated to $\langle T, \beta, \overrightarrow{Id}, T' \rangle$ by performing a 1-move, as shown in Section 3.

Figure 10: A diagram containing a ribbon connecting $c$ to $c'$, and its reduction.
**Definition 26.** Let $T$ and $T'$ be two full finite $n$-ary trees. The least common multiple of $T$ and $T'$ is the minimal full finite $n$-ary tree $T''$ with respect of expansions such that $T \subseteq T''$ and $T' \subseteq T''$ as rooted full finite $n$-ary trees. See Figure 11.

![Figure 11: The third tree is the least common multiple of the first two.](image)

Let $R$ be the tree of depth 1. Define the ‘spine’ tree $S_d$ of depth $d$ as the full finite $n$-ary tree constructed inductively from $R$ by expanding its last leaf, that is:

$$S_d = R[n-1][(n-1)(n-1)] \ldots [(n-1) \ldots (n-1)].$$

The proof of the following proposition gives a way to decompose elements of $BV_n(H)$.

**Proposition 27.** Let $v = (T_1, \beta, \lambda, T_2)$ be an element of $BV_n(H)$ such that $T_1$ (and $T_2$) has depth $d > 4$. Then we can express $v$ as a product of elements in $BV_n(B_n)$ having depth less than $d$. Let $T_3$ be a tree of depth $d$ with exactly $3$ final carets. Then, each factor $(T'_1, \beta', \lambda', T'_2)$ satisfies one of the following properties:

- $T'_2 = T_3$, $\beta'$ is a ribbon and $\lambda' = \overrightarrow{Id}$.
- $T'_1 = T_3$, $\beta'$ is a ribbon and $\lambda' = \overrightarrow{Id}$.
- $T'_1 = T'_2 = T_3$, $\beta' = \sigma_i^{\pm 1}$, where $\sigma_i$ is an Artin generator and $\lambda' = \overrightarrow{Id}$.
- $T'_1 = T'_2$ has depth $1$, $\beta'$ is trivial and $\lambda' = \{\sigma_i^{\pm 1}, \overrightarrow{Id}, \ldots, \overrightarrow{Id}\}$, where $\sigma_i$ is an Artin generator.

The moral of the proof, as well as in (Higman, 1974), is to decompose any element $v \in BV_n(H)$ of depth $d \geq 4$ into a product of elements which have less depth than $v$. We firstly do it for elements of $BV_n$, and then we deal recursive braids.

**Proof.** Let $c_1$ be a final caret of $T_1$ and let $c_2$ be a final caret of $T_2$. Let also $c_3$ and $c_4$ be two different final carets of $T_3$. Consider the ribbon $r_1$ connecting $c_1$ to $c_3$ and the ribbon $r_2$ connecting $c_4$ to $c_2$. Then

$$\left( T_1, \beta, \overrightarrow{Id}, T_2 \right) \equiv \left( T_1, r_1^{-1} \beta r_2^{-1} r_2, \overrightarrow{Id}, T_2 \right) \equiv \left( T_1, r_1 \overrightarrow{Id}, T_3 \right) \left( T_3, r_1^{-1} \beta r_2^{-1}, \overrightarrow{Id}, T_3 \right) \left( T_3, r_2, \overrightarrow{Id}, T_2 \right).$$

The diagram constructed from $(T_1, r_1, \overrightarrow{Id}, T_3)$ is not reduced, because there is a ribbon $r_1$ connecting $c_1$ to $c_3$ and one can perform a 1-move. Hence, the corresponding element has depth less than $d$. Using the same argument, the element represented by $(T_3, \overrightarrow{Id}, r_2, T_2)$ has depth less than $d$. Also notice that $(T_3, r_1^{-1} \beta r_2^{-1}, \overrightarrow{Id}, T_3)$ is equivalent to a product of elements of the form $(T_3, \sigma_i^{\pm 1}, \overrightarrow{Id}, T_3)$. Since $T_3$ has 3 final carets and $\sigma_i^{\pm 1}$ is a crossing of two consecutive strands, we can always reduce its diagram. This means that it has depth less than $d$. 

14
Let $T_4$ be the spine tree $S_d$. Let also $T_5$ be the full finite $n$-ary tree of depth 1 and notice that
the least common multiple of $T_4$ and $T_5$ is $T_4$, as $T_5 \subset T_4$. Suppose that we have $(T_1, \beta, \lambda_1, T_2)$,
where $\lambda_1 = \{\ell_1, \ldots, \ell_j, \ldots, \ell_m\}$. We show that is possible to obtain an element $(T_1, \beta, \lambda_1', T_2)$
from the previous one such that $\lambda_1' = \{\ell_1, \ldots, \ell_j \sigma_i^{\pm 1}, \ldots, \ell_m\}$ for some $\sigma_i$. Let $\gamma$ be any braid
performing the permutation $\gamma(j) = 1$, and $\lambda_{i,j} = \{\ell_k\}_{k=1}^m$ such that $\ell_j = \sigma_i^{\pm 1}$ and $\ell_k = Id$ if
$k \neq j$. Then, we have

$$(T_1, \beta, \lambda_1, T_2) \left( T_2, \gamma, \overrightarrow{T_d}, T_4 \right) (T_5, Id, \lambda_{i,1}, T_5) \left( T_4, \gamma^{-1}, \overrightarrow{T_d}, T_2 \right) \equiv (T_1, \beta, \lambda_1, T_2) \left( T_2, Id, \lambda_{i,j}, T_2 \right) \equiv (T_1, \beta, \lambda_2, T_2).$$

Since we have already shown that we can express $(T_2, \gamma^{\pm 1}, \overrightarrow{T_d}, T_4)$ using the desired generators,
this finishes the proof.

Note that the previous proof works for depth $d \geq 5$ because 5 is the minimal depth that $T_3$
can have for $n = 2$. Also notice that the previous proposition can be refined to obtain a set
of generators for $BV_n(H)$ if $H$ is finitely generated, by using recursive braids (labels) that
corresponds to the generators of $H$.

Let $T$ be the depth 1 tree. We define

$$T(n) = \begin{cases} T[0][1][00][01], & \text{if } n = 2, \\ T[0][1][2], & \text{if } n > 2. \end{cases}$$

Let $m(n)$ be the number of leaves of $T(n)$.

**Corollary 28.** For every $n \geq 2$, $BV_n(B_n)$ is finitely generated. In addition, every generator
has depth at most 5 (4 if $n \geq 3$), and has a tree pair representative $(T, \beta, \lambda, T')$ satisfying one
of the following conditions.

- $T' = T(n)$, $\beta = Id$ and $\lambda = \overrightarrow{T_d}$. This generator is denoted by $e_T$, regarding the domain
tree $T$ of $(T, \beta, \lambda, T')$.

- $T = T'$, $\beta = \sigma_i$, where $\sigma_i$ is an Artin generator of $B_{m(n)}$ and $\lambda = \overrightarrow{T_d}$. This
generator is denoted by $h_i$.

- $T = T'$ has depth 1, $\beta$ is trivial and $\lambda = \{\sigma_j, Id, \ldots, Id\}$, where $\sigma_j$ is an Artin generator
of $B_n$. This generator is denoted by $g_j$.

**Proof.** As one can always perform the inverse of a 1-move to a diagram, we can always apply
**Proposition 27** (performing the inverse of a 1-move corresponds to expanding the domain and
the range trees of the corresponding tree pair). Then, by applying induction on the depth
of elements, it follows that we can use as generators the elements described in **Proposition 27**
by replacing $T_3$ with $T(n)$. All these elements have depth less than 4 (or 3 if $n \geq 3$).

Notice that $(T(n), \sigma_i, \overrightarrow{T_d}, T(n))$ is the inverse of $(T(n), \sigma_i^{-1}, \overrightarrow{T_d}, T(n))$, so we can consider only
the first one as a generator. Analogously, we can discard the $(T, Id, \lambda, T)$ containing $\lambda = \{\sigma_j^{-1}, Id, \ldots, Id\}$. On the other hand, if $\beta$ is a ribbon, we have that

$$(T, \beta, \overrightarrow{T_d}, T(n)) \equiv (T, Id, \overrightarrow{T_d}, T(n)) \left( T(n), \beta, \overrightarrow{T_d}, T(n) \right).$$

Observe that $(T(n), \beta, \overrightarrow{T_d}, T(n))$ can be written as a product of elements with representatives
$(T(n), \sigma_i^{-1}, \overrightarrow{T_d}, T(n))$. Then use $(T, Id, \overrightarrow{T_d}, T(n))$ as a generator and get rid of $(T, \beta, \overrightarrow{T_d}, T(n))$.
Similarly, we can replace the generators of the form $(T(n), \beta, \overrightarrow{T_d}, T)$ by $(T(n), Id, \overrightarrow{T_d}, T)$. Finally,
notice that $(T(n), Id, \overrightarrow{T_d}, T)$ is the inverse of $(T, Id, \overrightarrow{T_d}, T(n))$, hence we can discard it.

\[ \square \]
Remark 29. Notice that the set of generators \( \{ e_T, h_1, \ldots, h_{m(n)-1} \} \), for all trees \( T \) of depth less than 5 (or 4 if \( n = 2 \)), generate all elements in \( BV_n \). Also, if \( S_H \) is a generating set for \( H \leq B_n \) and \( T \) is the \( n \)-ary tree of depth 1, we can substitute the set of generators \( g_j \) by the set of generators \((T, Id, \{ s, Id, \ldots, Id \}, T)\) for every \( s \in S_H \).

Example. Figure 12 is a visual example of how to decompose an element of \( BV_3(B_3) \), represented by \((T, \sigma_2, \{ \sigma_i, Id, \ldots, Id \}, T')\), using the generators of Corollary 28. Let \( T_d(3) \) be a \( n \)-ary tree of depth \( d \) with exactly \( 3 \) final carets. The reader will notice that, to make this example simpler, we always choose \( T_d(3) \) such that we already have the necessary (trivial) ribbons to reduce the depth of elements. We describe now the decomposition process.

The element \((T, \sigma_2, \{ \sigma_i, Id, \ldots, Id \}, T')\) has depth 5 and is decomposed as

\[
(T, Id, \overrightarrow{Id}, T_5(3)) (T_5(3), \sigma_2, \overrightarrow{Id}, T_5(3)) (T_5(3), Id, \overrightarrow{Id}, T') (T', Id, \overrightarrow{Id}, S_5) = (S_5, Id, \overrightarrow{Id}, T').
\]

1. The element \((T, Id, \overrightarrow{Id}, T_5(3))\) has a ribbon connecting the leftmost final carets of \( T \) and \( T_5(3) \). Then, there is an equivalent representative \((T_1, Id, \overrightarrow{Id}, T'_1)\) of depth 4 obtained by performing a 1-move that removes the previous final carets. This new representative is decomposed as the product \((T_1, Id, \overrightarrow{Id}, T(3))(T(3), Id, \overrightarrow{Id}, T'_1)\), where \( T_1 \) (resp. \( T'_1 \)) is a reduction of \( T \) (resp. \( T_5(3) \)).

2. The element \((T_5(3), \sigma_2, \overrightarrow{Id}, T_5(3))\) has a ribbon connecting the second final carets of both \( T_5(3) \)'s. Then, there is an equivalent representative \((T_2, \sigma_2, \overrightarrow{Id}, T_2)\) of depth 4 obtained by removing the previous final carets. This new representative is decomposed as the product

\[
(T_2, Id, \overrightarrow{Id}, T(3))(T(3), \sigma_2, \overrightarrow{Id}, T(3))(T(3), Id, \overrightarrow{Id}, T_2).
\]

3. The element \((T_5(3), Id, \overrightarrow{Id}, T')\) has a ribbon connecting the second final carets of \( T' \) and \( T_5(3) \). Then there is an equivalent representative \((T_3, Id, \overrightarrow{Id}, T'_3)\) of depth 4 obtained by removing the previous final carets. This new representative is decomposed as the product

\[
(T_3, Id, \overrightarrow{Id}, T(3))(T(3), Id, \overrightarrow{Id}, T'_3).
\]

4. The element \((T', Id, \overrightarrow{Id}, S_5)\) is decomposed as \((T', Id, \overrightarrow{Id}, T_5(3))(T_5(3), Id, \overrightarrow{Id}, S_5)\). In this case, one can redefine \( T_5(3) \) such that:

(a) The element \((T', Id, \overrightarrow{Id}, T_5(3))\) has a ribbon connecting the leftmost final carets of \( T' \) and \( T_5(3) \). Then there is an equivalent representative \((T_4, Id, \overrightarrow{Id}, T'_4)\) of depth 4 obtained by removing the previous final carets. This new representative is decomposed as the product \((T_4, Id, \overrightarrow{Id}, T(3))(T(3), Id, \overrightarrow{Id}, T'_4)\).

(b) \((T_5(3), Id, \overrightarrow{Id}, S_5)\) has a ribbon connecting the rightmost final carets of \( T' \) and \( T_5(3) \). Then there is an equivalent representative \((T_3, Id, \overrightarrow{Id}, T'_3)\) of depth 4 obtained by removing the previous final carets. This new representative is decomposed as the product \((T_3, Id, \overrightarrow{Id}, T(3))(T(3), Id, \overrightarrow{Id}, T'_3)\).

Therefore, the element \((T, \sigma_2, \{ \sigma_i, Id, \ldots, Id \}, T')\) is also represented by the word

\[
e_{T_1} e_{T_1}^{-1} e_{T_2} e_{T_2}^{-1} e_{T_3} e_{T_3}^{-1} e_{T_4} e_{T_4}^{-1} e_{T_4}^{-1} e_{T_5} e_{T_5}^{-1} e_{T_5}^{-1} e_{T_4}^{-1}.
\]

The set of generators in Corollary 28 can be further reduced. The following two lemmas will prove that we just need only one generator of type \( h_i \), namely \( h_{m(n)-1} \).
Figure 12: How to decompose $v \in BV_3(B_3)$ in generators of depth less than 5.
Lemma 30. The generators $h_i$, for $1 \leq i \leq n - 1$, of Corollary 28 can be expressed with words containing only generators of type $e$ and $g$.

Note that, once this lemma will be proved, the generators $h_i$ for $i \in \{n, \ldots, m(n) - 1\}$ will remain. They will be treated in the next lemma, proving that only $h_{m(n) - 1}$ is needed.

Proof. First of all, notice that $v_i := (T(n), \sigma_i, \lambda_i, T(n))$, where $\lambda_i = \{\overbrace{\sigma_i, \ldots, \sigma_i, Id, \ldots, Id}^{n}\}$ is equivalent to the generator $g_i$.

Define
\[
 w^{(k)}_i := (T(n), Id, \{\mu_j\}_{j=0}^{m(n)-1}, T(n)) \quad \text{where} \quad \begin{cases} 
 \mu_j = \sigma_i, & \text{if } j = k, \\
 \mu_j = Id, & \text{otherwise}.
 \end{cases}
\]

\[
 z_i := (T(n), \sigma_i, \{\xi_j\}_{j=0}^{m(n)-1}, T(n)) \quad \text{where} \quad \begin{cases} 
 \xi_j = \sigma_i, & \text{if } j \in \{i + 1, \ldots, n - 1\}, \\
 \xi_j = Id, & \text{otherwise}.
 \end{cases}
\]

for $i \in \{1, \ldots, n - 1\}$.

Claim. For any $i \in \{1, \ldots, n - 1\}$, the elements $z_i$ and $w^{(k)}_i$, with $0 \leq k \leq i$, can be generated by using only type $e$ and type $g$ generators.

We prove it by induction. For $k = 0$, $w^{(0)}_i := e^{-1}S_d$, where $S_d$ is a spine tree and $d$ is the depth of $T(n)$ depending on whether $n = 2$ or not. Suppose that the claim holds for $j < k < i$. We need to prove that we can generate $w^{(k)}_i$. Denote by $r_p$ the braid $\sigma_p\sigma_{p-1}\cdots\sigma_1$ for $p > 1$ and consider the element represented by $r(k) := z_kz_{k-1}\cdots z_1$ for $0 \leq k < i$. A representative of this element is $(T(n), r_k, \rho_k, T(n))$, where

\[
 \rho_k = \{Id, Id, r_1, r_2, \ldots, r_k, r_{k+1}, \ldots, r_{n-2}, Id, \ldots, Id\}.
\]

Then we have that $w^{(k)}_i \equiv r(k)e^{-1}S_d(k)^{-1}$, for $0 \leq k < i$ (see Figure 13).

Now define $x_i := v_i \left(w^{(i-1)}_i\right)^{-1}$, so $w^{(i)}_i \equiv v_i x_i^{-1}$ (see Figure 14). To finish the proof of the claim, notice that $z_i \equiv v_i \left(w^{(0)}_i\right)^{-1} \left(w^{(1)}_i\right)^{-1} \cdots \left(w^{(i)}_i\right)^{-1}$.

To prove the statement of the lemma, we also proceed by induction. For $i = n - 1$, $h_{n-1} = z_{n-1}$. Now suppose that the statement holds for $i + 1$, we prove it for $i$. By Claim 1, we have seen that $w^{(i-1)}_i$ can be expressed using generators of type $e$ and $g$. We prove that $h_i$ is equal to the following product:

\[
 h_{i+1}w^{(i-1)}_i z_i h_{i+1} z_i^{-1} \left(w^{(i-1)}_i\right)^{-1} h_{i+1}^{-1}.
\]

Notice that $z_i h_{i+1} z_i^{-1} \equiv (T(n), \sigma_i, \sigma_{i+1}^{-1}, \{\nu_j\}_{j=0}^{m(n)-1}, T(n))$, where $\nu_{i-1} = \sigma_i$, $\nu_{i+1} = \sigma_i^{-1}$ and $\nu_j = Id$ if $j \neq i, i + 2$ (see Figure 15). By the braid relation $\sigma_i \sigma_{i+1}^{-1} = i + 2$, the conjugate of $(T(n), \sigma_i, \sigma_{i+1}^{-1}, \{\nu_j\}_{j=0}^{m(n)-1}, T(n))$ by $w^{(i-1)}_i$ has trivial labels. Hence we obtain

\[
 h_{i+1} \left(T(n), \sigma_i, \sigma_{i+1}^{-1}, T(n)\right) h_{i+1}^{-1} \equiv (T(n), \sigma_{i+1}, \sigma_{i+1}^{-1}, \sigma_{i+1}^{-1} \sigma_{i+1}^{-1}, T(n))
\]

By using braid relations we know that $\sigma_{i+1} \sigma_i \sigma_{i+1}^{-1} \sigma_{i+1}^{-1} = \sigma_i$, so the expression is equivalent to $h_i$, as we wanted to prove. \qed

18
Figure 13: $w_i^{(2)} \equiv r(2)e_S^{-1} g_i e_S r(2)^{-1}$ for $n = 4$. Consider the diagrams up to equivalence to match the labels.

Figure 14: $w_i^{(1)} \equiv v_1 x_1^{-1}$ for $n = 3$. Consider the diagrams up to equivalence to match the labels.
Figure 15: \( z_2 h_3 z_2^{-1} \equiv (T(4), \sigma_2 \sigma_3 \sigma_2^{-1}, \nu_2, T(4)) \) for \( n = 4 \). Consider the diagrams up to equivalence to match the labels.

**Lemma 31.** All generators \( h_i \), for \( i \geq n \), can be expressed in terms of generators \( h_i \) for \( i < n \) and \( h_{m(n)-1} \).

**Proof.** We proceed by induction. Let \( c \) be the right-most final caret of \( T(n) \):

\[
c = \begin{cases} \{10, 11\} & \text{if } n = 2, \\ \{20, \ldots, 2(n-1)\} & \text{otherwise.} \end{cases}
\]

Let also

\[
T_1 = \begin{cases} T(n)[c]^{-1}[000] & \text{if } n = 2, \\ T(n)[c]^{-1}[00] & \text{otherwise;} \end{cases} \quad \text{and} \quad T_2 = \begin{cases} T(n)[c]^{-1}[001] & \text{if } n = 2, \\ T(n)[c]^{-1}[01] & \text{otherwise.} \end{cases}
\]

Note that \( h_1 \equiv (T_1, \sigma_n \sigma_{n-1} \ldots \sigma_1, \text{Id}, T_2) \). Hence we have the product (see Figure 16):

\[
h_n \equiv \left( T(n), \text{Id}, \text{Id}, T_1 \right) h_1 \left( T_2, \text{Id}, \text{Id}, T(n) \right) h_1^{-1} h_2^{-1} \cdots h_{n-1}^{-1}.
\]

Suppose that the statement of the lemma is true for every \( j < i \) when \( i > n \), and let \( T'(n) := T(n)[c]^{-1}[n-1] \) for \( n > 3 \), that is, the tree obtained from \( T(n) \) by attaching a final caret to its last leaf and erasing the final caret \( c \). If \( n = 2, 3 \), we set \( T'(n) = T(n) \). Also let \( T''(n) := T(n)[\{(n-1)0, \ldots, (n-1)(n-1)\}]^{-1}[0] \). Notice that, for \( 1 < i < m(n) - n \), we have

\[
\left( T'(n), \sigma_i, \text{Id}, T'(n) \right) \equiv \left( T''(n), \sigma_{i+n-1}, \text{Id}, T''(n) \right)
\]

Then we obtain \( h_i \) using the following product (see Figure 17):

\[
h_i \equiv \left( T(n), \text{Id}, \text{Id}, T''(n) \right) \left( T'(n), \text{Id}, \text{Id}, T(n) \right) h_{i-n+1} \left( T(n), \text{Id}, \text{Id}, T'(n) \right) \left( T''(n), \text{Id}, \text{Id}, T(n) \right).
\]

\( \Box \)
Figure 16: \( h_3 \equiv (T(3), Id, T_1)h_1(T_2, Id, T(n))h_1^{-1}h_2^{-1} \) for \( n = 3 \).

Figure 17: How to shift a crossing to the right using conjugation when \( n = 4 \). Consider the diagrams up to equivalence to match the labels.

The generators of type \( e \) belong to the well studied Thompson’s group \( F_n \), consisting of all elements represented by triples \( (T, \tau, T') \) where \( \tau \) is trivial. This group is finitely generated:

**Lemma 32** (Brown, 1987, Cannon et al., 1996). The generators of type \( e \) in Corollary 28 can be generated by using the \( n \) elements \( x_0, \ldots, x_{n-1} \) depicted in Figure 18.

Therefore, we have proved that the \( 2n \) elements in Theorem 24, which are precisely \( x_0, \ldots, x_{n-1}, h_{m(n)-1}, g_1, \ldots, g_{n-1} \), generate \( BV_n(H) \).

\[ \begin{align*}
\cdots & \xrightarrow{x_i} \cdots, \\
i & \in \{0, \ldots, n-2\}
\end{align*} \]

\[ \begin{align*}
\cdots & \xrightarrow{x_{n-1}} \cdots.
\end{align*} \]

Figure 18: Generators of \( F_n \).

### 4.1.1 Other generating systems for specific subgroups \( H \)

The reader must have noticed that in most of the cases, the set of generators given in Theorem 24 is not contained in \( BV_n(H) \).

If \( H \) is trivial, Remark 29 together with Lemma 31 and Lemma 32 provide another set of \( 2n \) generators for \( BV_n \) that is contained in \( BV_n \). These elements are \( x_1, \ldots, x_n, h_1, \ldots, h_{n-1}, h_{m(n)-1} \). In particular, \( BV_2 \) is generated by \( x_1, x_2, h_1 \) and \( h_5 \). The generators of \( BV_2 \) given by Brin (2006) are also four: \( x_1, x_2, h_1 \) and \( (R, \sigma, 1, R) \), where \( R \) is the tree of depth 1.

In general, if there is a known generating system \( S_H \) for \( H \), one can use the three mentioned results to obtain a generating system

\[ \{(R, Id, \{s, Id, \ldots, Id\}, R)| s \in S_H\} \cup \{x_1, \ldots, x_n, h_1, \ldots, h_{n-1}, h_{m(n)-1}\}. \]

### 4.2 The specific case when \( H \) is a parabolic subgroup.

An important type of subgroups \( H \) are parabolic subgroups. If \( \Sigma \) is the set of Artin generators of \( B_n \), a standard parabolic subgroup \( A_X \) is the subgroup of \( B_n \) generated by a subset \( X \subset S \). A parabolic subgroup is defined as any conjugate of a standard parabolic subgroup. To obtain a set of \( 2n \) generators in \( BV_n(A_X) \), one shall slightly modify the proof of Lemma 30:

**Lemma 33.** Let \( X \) be a subset of the Artin generators \( \Sigma \) of \( B_n \). The generators \( h_i \) in Corollary 28 such that \( \sigma_i \in X \) can be expressed as a word using generators of type \( e \), \( h_j \) such that \( \sigma_j \in \Sigma \setminus X \) and \( g_i \) such that \( \sigma_i \in X \).

**Proof.** As for Lemma 30, let

\[ w_i^{(k)} := (T(n), Id, \{\mu_j\}_{j=0}^{m(n)-1}, T(n)) \] where \[ \begin{align*}
\mu_j & = \sigma_i, \text{ if } j = k, \\
\mu_j & = Id, \text{ otherwise.}
\end{align*} \]

\[ z_i := (T(n), \sigma_i, \{\xi_j\}_{j=0}^{m(n)-1}, T(n)) \] where \[ \begin{align*}
\xi_j & = \sigma_i, \text{ if } j \in \{i+1, \ldots, n-1\}, \\
\xi_j & = Id, \text{ otherwise.}
\end{align*} \]

for \( i \in \{1, \ldots, n-1\} \). Let also \( I := \{i \mid \sigma_i \in X\} \).

**Claim.** For any \( i \in I \), the elements \( z_i \) and \( w_i^{(k)} \), with \( 0 \leq k \leq i \), can be expressed by using generators of type \( e \), \( h_j \) such that \( j \notin I \) and \( g_i \) such that \( i' \in I \).

For \( k = 0 \), \( w_i^{(0)} \equiv e_S g_i e_S \), where \( S \) is the spine tree of same depth as \( T(n) \). We have also seen that if \( x_i := g_i \left( w_i^{(i-1)}\right)^{-1} \), then \( w_i^{(i)} \equiv g_i x_i^{-1} \). Since \( z_i \equiv g_i \left( w_i^{(0)}\right)^{-1} \left( w_i^{(1)}\right)^{-1} \cdots \left( w_i^{(i)}\right)^{-1} \), we have to prove that \( w_i^{(k)} \) is generated as desired, for \( 1 \leq k < i \).
Suppose that the claim holds for \( j < k < i \). Denote by \( r_p \), the element \( \sigma_p\sigma_{p-1}\cdots\sigma_1 \) for \( p > 1 \) and let \( r'_p := \sigma'_p\sigma'_{p-1}\cdots\sigma'_1 \) where \( \sigma'_q = \sigma_q \) if \( q \in I \) and \( \sigma'_q = \text{Id} \), if \( q \notin I \). Consider the element represented by \( r(k) := z_k'z_{k-1}'\cdots z_1' \) for \( 0 \leq k < i \), where \( z_q' = z_q \) if \( q \in I \) and \( z_q' = h_q \), if \( q \notin I \). A representative of this element is \((T(n), r_k, \rho_k, T(n))\) where

\[
\rho_k = \{ \text{Id, Id, } r'_1, r'_2, \ldots, r'_{k+1} \}.
\]

Then we have that \( w_i^{(k)} \equiv r(k)G^{-1}g_iG_{\cdot}r(k)^{-1} \), for \( 0 \leq k < i \). This finishes the proof of the claim.

Finally, as \( h_{n-1} = h_{n-1} \), the result follows by induction using the product:

\[
h_{i+1}w_i^{(i-1)}z_ih_{i+1}z_i^{-1}w_i^{(i-1)}h_{i+1}^{-1}.
\]

\[\square\]

**Proposition 34.** Let \( X \) be a subset of the Artin generators \( \Sigma \) of \( B_n \). Then \( BV_n(A_X) \) is generated by \( 2n \) elements in \( BV_n(A_X) \), namely the set

\[
\{ x_0, \ldots, x_{n-1} \} \cup \{ h_i | \sigma_i \in \Sigma \setminus X \} \cup \{ h_{m(n)-1} \} \cup \{ g_i | \sigma_i \in X \}.
\]

Similarly, \( BV_n(\alpha^{-1}A_X\alpha) \), \( \alpha \in B_n \), is generated by the following set of \( 2n \) elements:

\[
\{ \alpha^{-1}x_0h_\alpha, \ldots, \alpha^{-1}x_{n-1}h_\alpha \} \cup \{ \alpha^{-1}h_\alpha h_\alpha | \sigma_i \in \Sigma \setminus X \} \cup \{ \alpha^{-1}h_{m(n)-1}h_\alpha \} \cup \{ \alpha^{-1}g_\alpha^{-1}g_\alpha h_\alpha | \sigma_i \in X \},
\]

where \( \alpha := (T(n), \alpha, \text{Id}, T(n)) \), \( g_\alpha := (R, \text{Id, } \{ \alpha, \text{Id, } \ldots, \text{Id} \}, R) \) and \( R \) is the \( n \)-ary tree of depth \( 1 \).

**Proof.** For \( A_X \), this a direct consequence of Remark 29, Lemma 31, Lemma 32 and Lemma 33. As conjugacy defines a group isomorphism, it is easy to proof (see Remark 29) that

\[
\alpha^{-1}x_0h_\alpha, \ldots, \alpha^{-1}x_{n-1}h_\alpha \cup \alpha^{-1}h_\alpha h_\alpha | \sigma_i \in \Sigma \setminus X \} \cup \alpha^{-1}h_{m(n)-1}h_\alpha \cup \alpha^{-1}g_\alpha^{-1}g_\alpha h_\alpha | \sigma_i \in X \}
\]

generates \( BV_n(\alpha^{-1}A_X\alpha) \). This set can be reduced to

\[
\alpha^{-1}x_0, \ldots, x_{n-1}, h_1, \ldots, h_{m(n)-1}h_\alpha \cup \alpha^{-1}g_\alpha^{-1}g_\alpha h_\alpha | \sigma_i \in X \}
\]

by reproducing the proof of Lemma 31 with all elements conjugated by \( h_\alpha \). We need to show that one does not need \( h_i \) such that \( \sigma_i \in X \) in this generating system. To prove that, we encourage the reader to rewrite the proof of Lemma 33, doing the following conjugacy changes:

- Redefine \( w_i^{(k)} := \alpha^{-1}T(n), \text{Id, } \{ \mu_j \}_{j=0}^{m(n)-1}, T(n) \}h_\alpha \) with \( \mu_k = \alpha^{-1}\sigma_i\alpha \) and \( \mu_j = \text{Id} \) when \( j \neq k \).
- Redefine \( z_i := \alpha^{-1}T(n), \sigma_i, \{ \xi_j \}_{j=0}^{m(n)-1}, T(n) \}h_\alpha \) with \( \xi_j = \alpha^{-1}\sigma_i\alpha \) when \( j = i + 1, \ldots, n-1 \) and \( \xi_j = \text{Id} \) otherwise.
- Conjugate generators of type \( e \) and \( h \) by \( h_\alpha \) and conjugate generators of type \( g \) by \( g_\alpha h_\alpha \).
- Conjugate all \( \sigma_q \) by \( \alpha \).

\[\square\]
4.3 Finite generation for $BV_{n,r}(H)$ and $\widehat{BV}_n(H)$

It is straightforward to prove that the groups $BV_{n,r}(H)$ and $\widehat{BV}_n(H)$ are finitely generated by using that $BV_n(H)$ is finitely generated together with a result of (Brown, 1987), whose proof is included here by completeness.

**Theorem 35.** Let $H \leq B_n$ and $n \geq 2$. Then:

$$BV_{n,r}(H) \cong \widehat{BV}_n(H)$$

for every $r \geq 1$.

**Proof.** The proof is the same as in (Brown, 1987), where it is shown that $V_{n,r}$ is isomorphic to $\widehat{V}_n$ for every $r \geq 1$.

Every $V_{n,r}$ contains an isomorphic copy of $\widehat{V}_n$ in the following way: consider the set of $r$ roots of $V_{n,r}$ and expand the last one by adding a final caret to the root $x_{r-1}$. We continue this process expanding the rightmost leave of the resulting tree, and so on. The final result is an infinite right spine appended to the last root $x_{r-1}$. The isomorphism from $V_{n,r}$ to $\widehat{V}_n$ takes the ordered set of leaves of the previous element to the infinite set of roots of $\widehat{V}_n$, see Figure 19. Note that the isomorphism does not depend on braids or recursive braids, so it can be easily adapted to the case of $BV_{n,r}(H)$.

**Corollary 36.** If $H \leq B_n$ is finitely generated, the groups $BV_{n,r}(H)$ and $\widehat{BV}_n(H)$ are finitely generated for all $n \geq 2$, $r \geq 1$.

![Figure 19: The isomorphism between $V_{n,r}$ and $\widehat{V}_n$.](image)
