Abstract

A light-like Wilson loop is computed in perturbation theory up to $O(g^4)$ for pure Yang–Mills theory in 1+1 dimensions, using Feynman and light–cone gauges to check its gauge invariance. After dimensional regularization in intermediate steps, a finite gauge invariant result is obtained, which however does not exhibit abelian exponentiation. Our result is at variance with the common belief that pure Yang–Mills theory is free in 1+1 dimensions, apart perhaps from topological effects.

1. Introduction

While an abundant literature is by now available concerning “euclidean” QCD in two dimensions [1], [2], [3] comparatively fewer investigations have been performed in minkowskian 1+1 dimensions.

It is a common belief, taking rise from the pioneeristic work of ’t Hooft [4], that Yang–Mills theory (YMT) without fermions in two dimensions is a free theory apart perhaps from topological effects. As a matter of fact, the gauge field should not be endowed with any dynamical degree of freedom. This can naively be seen in axial gauges, where one of the components of the vector potential is set equal to zero. It is also at the root of the possibility of calculating the mesonic spectrum in the large N approximation [4], [5], when quarks are introduced.

However the theory exhibits severe infrared (IR) divergences which need to be regularized. In ref. [4] an explicit IR cutoff is advocated, which turns out to be uninfluential in the bound state equation; a Cauchy principal value (CPV) prescription in handling such IR singularity leads indeed to the same result [6]. Still difficulties in performing a Wick’s rotation in those conditions have been pointed out [7], and a causal prescription for the IR singularity has been advocated, leading to a quite different solution for the vector propagator. In this context the bound state equation with vanishing bare quark masses [8] has solutions with quite different properties, when compared with the ones of refs.[4],[5].

In view of the above mentioned controversial results and of the fact that “pure” YMT does not immediately look free in Feynman gauge, where degrees of freedom of a “ghost”-type are present, we have thought worth performing a test on a gauge invariant quantity. We have chosen a rectangular Wilson loop with light–like sides, directed along the vectors $n_\mu = (T, -T)$ and $n^*_\mu = (L, L)$, parametrized according to the equations:

\begin{align}
C_1 : x^\mu(t) &= n^*\mu t, \\
C_2 : x^\mu(t) &= n^\mu + n^*\mu t, \\
C_3 : x^\mu(t) &= n^\mu + n^*\mu (1 - t), \\
C_4 : x^\mu(t) &= n^\mu (1 - t), \quad 0 \leq t \leq 1. \tag{1.1}
\end{align}

This contour has been considered in refs. [9],[10] for an analogous test of gauge
invariance in 1+3 dimensions. Its light–like character forces a Minkowski treatment.

We shall perform a perturbative calculation up to $O(g^4)$; in so doing topological effects will not be considered. We can anticipate the unexpected results we will obtain: the gauge invariant theory is not free at $d=1+1$, at variance with the commonly accepted behaviour; the theory in $d=1+(D-1)$ is “discontinuous” in the limit $D \to 2$.

2. The calculation in Feynman gauge

In Feynman gauge already the free vector propagator does not exist as a tempered distribution in 1+1 dimensions. A regularization is thereby mandatory and we choose from here on to adopt the dimensional regularization, which preserves gauge invariance:

$$D^F_{\mu\nu}(x) = -g_{\mu\nu} \frac{T^{-D/2}}{4} \Gamma(D/2 - 1)(-x^2 + i\epsilon)^{1-D/2}, \quad (2.1)$$

The calculation in Feynman gauge of the light–like Wilson loop (1.1), in 1+$D-1$ dimensions up to $O(g^4)$ has been performed in ref. [9] and will not be repeated here. Actually in ref. [9] part of the contribution from graphs containing three vector lines, has only been given as a Laurent expansion around $D=4$, owing to its complexity. In the following we shall exhibit its general expression in terms of a generalized hypergeometric series and then we shall expand it around $D=2$. We only report for the reader’s benefit the final results concerning the contributions of the various diagrams.

The single vector exchange ($O(g^2)$) gives

$$W^{(1)}_F = -\left(\frac{\hat{g}}{\pi \mu}\right)^2 C_F \frac{\Gamma(D/2 - 1)}{(D-4)^2} C, \quad (2.2)$$

where $\hat{g}^2 = g^2(\mu^2)^{D/2-1}$, $\mu$ being the running renormalization mass, $C_F$ is the Casimir operator of the fundamental representation of color $su(N)$ and

$$C \equiv \left[ (2\pi \mu^2 nn^* + i\epsilon)^{2-D/2} + (-2\pi \mu^2 nn^* + i\epsilon)^{2-D/2} \right]. \quad (2.3)$$

One immediately notice that the propagator pole at $D=2$ is cancelled after integration over the contour, leading to a finite result.
At order $\mathcal{O}(g^4)$ we can restrict ourselves to the so-called “maximally non-abelian” contributions [11]. The self-energy correction to the propagator gives

$$W^{(2; se)}_F = \left( \frac{\hat{g}}{\pi \mu} \right)^4 \frac{C_F C_A}{64} \frac{\Gamma^2(D/2 - 1)(3D - 2)}{(D - 4)^3(D - 3)(D - 1)} A, \quad (2.4)$$

where $C_A$ is the Casimir operator of the adjoint representation,

$$A \equiv [(2\pi \mu^2 nn^* + i\epsilon)^{4-D} + (-2\pi \mu^2 nn^* + i\epsilon)^{4-D}] \quad (2.5)$$

and the fermionic loop has not been considered (pure YMT). Eq. (2.4) exhibits a double pole at $D=2$.

Next we consider the contribution of the so-called “cross” graphs, the ones with two non interacting crossed vector exchanges

$$W^{(2; cr)}_F = -\left( \frac{\hat{g}}{\pi \mu} \right)^4 \frac{C_F C_A}{16} \frac{\Gamma^2(D/2 - 1)}{(D - 4)^4} \left[ A + 8B(1 - \frac{\Gamma^2(3 - D/2)}{\Gamma(5 - D)}) \right], \quad (2.6)$$

where

$$B \equiv [(2\pi \mu^2 nn^* + i\epsilon)(-2\pi \mu^2 nn^* + i\epsilon)]^{2-D/2}. \quad (2.7)$$

Again a double pole occurs at $D=2$.

The contribution coming from graphs with three vector lines is by far the most complex one. It is convenient to split it into two parts, one coming from graphs with two vector lines attached to the same side

$$W^{(2; ss)}_F = \left( \frac{\hat{g}}{\pi \mu} \right)^4 \frac{C_F C_A}{16} \frac{A}{(D - 4)^4} \left[ 2\Gamma(3-D/2)\Gamma(D/2-1)\Gamma(D-3) - \frac{1}{D-3} \Gamma^2(D/2-1) \right] \quad (2.8)$$

and another one in which the three “gluons” end in three different rectangle sides

$$W^{(2; ds)}_F = \left( \frac{\hat{g}}{\pi \mu} \right)^4 \frac{C_F C_A}{64} A \left\{ \frac{\Gamma^2(D/2 - 2)\Gamma(4 - D/2)\Gamma(D-3)}{\Gamma(D/2)} F(D) + \frac{4}{(D - 4)^4} \left[ \Gamma(3-D/2)\Gamma(D/2-1)\Gamma(D-3) - \Gamma^2(D/2-1) \right] \right\}. \quad (2.9)$$

The function $F(D)$ is defined as

$$F(D) = S(D) + \frac{D/2 - 1}{(3 - D/2)(D - 4)} \left[ 5\psi(3-D/2) - \psi(D/2 - 1) - 2\psi(1) \right]$$
\[ -2\psi(5 - D), \quad (2.10) \]

\[ \psi(D) \text{ being the digamma function and } S(D) \text{ the convergent generalized hypergeometric series} \]

\[ S(D) = \sum_{n=0}^{\infty} \frac{1}{(n+1)^2} \frac{\Gamma(n + D - 3) \Gamma(n + 4 - D/2)}{n! \Gamma(D - 3) \Gamma(4 - D/2) \Gamma(n + D/2)}. \quad (2.11) \]

Both contributions exhibit a double pole at \( D=2 \). The Laurent expansion of eq. (2.9) around \( D=4 \), reproduces exactly the expression given in ref. [9].

Summing eqs. (2.4), (2.6), (2.8) and (2.9) and performing a careful Laurent expansion around \( D=2 \), it is tedious but straightforward to prove that double and single poles cancel, leaving only the finite contribution

\[ W^{(2)}_F(D = 2) = \left( \frac{g^2}{4\pi} \right)^2 C_F C_A (n^* n)^2 (1 + \frac{\pi^2}{3}). \quad (2.12) \]

The presence of a non vanishing \( C_F C_A \) contribution is a dramatic result: it means that the theory does not exponentiate in an abelian way, as a “bona fide” free theory should do. In order to better understand this result, it is worth turning now our attention to the same Wilson loop calculation, performed in the light–cone axial gauge \( nA = 0 \).

3. The calculation in light–cone gauge \( nA = 0 \)

The free vector propagator in light–cone gauge is very sensitive to the prescription used to handle the so–called “spurious” singularity. The only prescription, known so far, which allows to perform a Wick’s rotation without extra terms and to calculate loop diagrams in a consistent way [12] is the causal Mandelstam–Leibbrandt (ML) prescription [13]. In a canonical formalism it is obtained by imposing equal time commutation relations [14]; in two dimensions a “ghost” degree of freedom still survives, as will be discussed in the last section.

When ML prescription is adopted, the free vector propagator is indeed a tempered distribution at \( D=2 \) [15], at variance with its behaviour in Feynman gauge. In particular, when \( x_\perp = 0 \),

\[ n^\mu n^\nu D^{LC}_{\mu\nu}(x) = \frac{2\pi^{-D/2} \Gamma(D/2)}{4 - D} \frac{(xn^*)^2}{(-x^2 + i\epsilon)^{D/2}}. \quad (3.1) \]
The calculation of the Wilson Loop under consideration at $O(g^4)$ in $1 + (D - 1)$ dimensions, using light–cone gauge, has been performed in ref. [10]. Here we shall report those results and then perform their Laurent expansion around $D=2$, the value we are interested in.

One might wonder why dimensional regularization should be introduced at all, as one might presume that single graph contributions are likely to be finite in this gauge. On the other hand, while remaining strictly at $D=2$, no self–interaction should be present.

We shall discuss this point of view at the end of the paper. For the time being let us recall that, when $D \neq 2$, “transverse” vector components are turned on and, although their contribution is expected to be $O(D - 2)$, it can compete with singularities arising from loop corrections. This is indeed what happens in the self–energy calculation, as will be soon apparent.

The calculation $O(g^2)$ is easily performed and the result exactly coincides with eq. (2.2), for any value of $D$. At $O(g^4)$ we again confine ourselves to the “maximally non–abelian” contributions, without losing information. The self–energy graph now gives

$$W^{(2;se)}_{LC} = \left( \frac{\hat{g}}{\pi \mu} \right)^4 C_F C_A \left\{ \frac{4}{(4-D)^4(D-3)} \left[ \frac{\Gamma^2(3-D/2)\Gamma(D-3)}{\Gamma(5-D)} \right] - \Gamma^2(D/2 - 1) \right\}.$$

Its limit at $D = 2$

$$W^{(2;se)}_{LC}(D = 2) = \left( \frac{g^2}{4\pi} \right)^2 C_F C_A (n^* n)^2$$

is finite, but it does not vanish, as one might have naively expected.

Similarly the contribution from the “cross” graphs

$$W^{(2;cr)}_{LC} = -\left( \frac{\hat{g}}{\pi \mu} \right)^4 C_F C_A \frac{\Gamma^2(D/2 - 1)}{(D - 4)^4} \left\{ 2A \frac{D - 2}{D - 3} + 8B[1 - 2\frac{\Gamma^2(3-D/2)}{\Gamma(5-D)}] \right\}.$$

leads to a finite, non vanishing, result in the limit $D=2$

$$W^{(2;cr)}_{LC}(D = 2) = \left( \frac{g^2}{4\pi} \right)^2 C_F C_A (n^* n)^2 \frac{\pi^2}{3}.$$
Summing eq. (3.3) and (3.5) we exactly recover eq. (2.12).

As a matter of fact the contribution due to graphs with three “gluon” lines [10]

\[ W_{LC}^{(2;3g)} = \Omega \left\{ \Gamma(D/2 - 2) \Gamma(3 - D/2) + \right. \\
\left. \frac{\Gamma^2(3 - D/2)}{\Gamma(5 - D)} \frac{6D - 28}{(D - 2)(D - 4)} - \frac{2}{\Gamma(2 - D/2)} S_1(D) - (4 - D) \Gamma(3 - D/2) S_2(D) \right\} 
\]

where

\[ \Omega = \frac{2g^4 C_F C_A}{(2\pi)^D} (2\pi n)^4 e^{-\pi D} \frac{\Gamma(D - 4)}{(D - 4)^2}, \]

\[ S_1(D) = \sum_{n=0}^{\infty} \frac{\Gamma(n + 2 - D/2)}{(n + 3 - D/2)n!} [\psi(n + D/2) - \psi(n + 3 - D/2) + \\
+ \frac{2}{(n + D/2 - 1)(n + D/2)} + \frac{1}{n + 3 - D/2} - \frac{\Gamma(n + D/2 - 1) \Gamma(5 - D)}{\Gamma(4 + n - D/2)} ] \]

and

\[ S_2(D) = \sum_{n=0}^{\infty} \frac{\Gamma(n + 3 - D/2)}{\Gamma(n + 6 - D)} [\Gamma(D/2 - 2) \left( \frac{\Gamma(n + 5 - D)}{\Gamma(n + 3 - D/2)} - \frac{\Gamma(n + 2)}{\Gamma(n + D/2)} \right) + \\
+ 2 \frac{\Gamma(n + 1) \Gamma(D/2)}{\Gamma(n + 1 + D/2)} + \frac{\Gamma(n + 5 - D) \Gamma(D/2 - 1)}{\Gamma(n + 4 - D/2)} - \frac{\Gamma(n + 1) \Gamma(3 - D/2)}{\Gamma(n + 4 - D/2)} ] \]

vanishes when D = 2.

As a consequence the same finite result for the Wilson loop \( O(g^4) \) at D=2 is obtained both in Feynman and in light–cone gauges. However non–abelian terms are definitely present; the theory cannot be considered a free one in quantum loop calculations at D=2, in spite of the quadratic nature of its classical lagrangian density in light–cone gauge. From a practical view point, in this fully interacting theory, the hope of getting solutions, when quarks are included, e.g. for the mesonic spectrum, in analogy with ‘t Hooft’s treatment, seems to us remote.
4. The ’t Hooft approach

In this section we stick in 1+1 dimensions. If we interpret $x^-$ as time direction, the field $A^-$ is not an independent dynamical variable and just provides a non-local force of Coulomb type between fermions. In momentum space it can be described by the “exchange” $k_+^{-2}$ [4].

Owing to its singular IR behaviour, this expression is not a tempered distribution; however it can be Fourier transformed after an analytical regularization

$$D_{--} (x) = \frac{i}{(2\pi)^2} \int e^{ikx} d^2k |k_+|^{-2\lambda} \delta_{\lambda=1}. \quad (4.1)$$

Alternatively the same result can be obtained by interpreting the square as (minus) the derivative of the Cauchy principal value (CPV) distribution

$$D_{--} (x) = -\frac{i}{(2\pi)^2} \int e^{ikx} d^2k \frac{\partial}{\partial k_+} [\text{CPV} \left( \frac{1}{k_+} \right)] = -\frac{i}{2} |x_-| \delta(x_+). \quad (4.2)$$

It is straightforward to check that, by inserting eq. (4.2) in our Wilson loop, the result (2.2) at $O(g^2)$ is recovered.

At $O(g^4)$ in 1+1 dimensions, the only “a priori” surviving non-abelian contribution, which is due to “cross” graphs, vanishes using eq. (4.2). Henceforth no $C_F C_A$ term appears, in agreement with abelian exponentiation, but at variance with the result obtained (after regularization!) in Feynman gauge. On the other hand no fully consistent vector loop calculation would be feasible in 1+(D-1) dimensions, using a CPV prescription or introducing IR cutoffs [16].

If we perform instead an equal time canonical quantization, starting from the lagrangian density

$$L = \frac{1}{2} F^a_{+-} F^a_{+-} + \lambda^a n A^a, \quad (4.3)$$

$\lambda^a$ being Lagrange multipliers, by imposing the equal time commutation relations

$$[A^a_1(t, x), F^b_{01}(t, y)] = i\delta(x - y)\delta^{ab}, \quad (4.4)$$

we recover for the vector propagator exactly the ML prescription restricted at $D=2$. 

8
In this context the equation for the Lagrange multipliers

\[ n \partial \lambda^a = 0 \] (4.5)

is to be interpreted as a true equation of motion and the fields \( \lambda^a \) provide propagating degrees of freedom, although of a “ghost” type [14]. The potentials \( A^a \) have the momentum decomposition

\[ \tilde{A}^a(k) = u^a \delta'(k_+) + v^a \delta(k_+), \] (4.6)

\( \tilde{\lambda}^a(k) \) being proportional to \( u^a \): \( \tilde{\lambda}^a = k_- u^a \).

The canonical algebra (4.4) induces on \( u^a \) and \( v^a \) the algebra

\[ [v^a_\pm(k_-), u^b_\mp(q_-)] = \pm \delta(k_- - q_-) \delta^{ab}, \] (4.7)

\( v^a_\pm \) and \( u^a_\pm \) being defined as

\[ v^a(k_-) = \theta(k_-) v^a_+(k_-) + \theta(-k_-) v^a_a(-k_-), \]

\[ u^a(k_-) = \theta(k_-) u^a_+(k_-) - \theta(-k_-) u^a_a(-k_-), \]

all others commutators vanishing.

This algebra eventually produces the propagator (3.1) for \( D=2 \). No wonder then that we recover from the “cross” graphs eq. (3.5), whereas, in strictly 1+1 dimensions, neither self–energy corrections nor graphs with three vector lines should be considered.

The result we obtain in this third scenario neither coincides with the one in Feynman gauge (the limit \( D \to 2 \) being “discontinuous”) , as we have neglected the non–vanishing self–energy correction, nor obeys abelian exponentiation as in ’t Hooft’s approach, the reason being rooted in a different content of the degrees of freedom (the fields \( \lambda^a \)). Although perhaps more satisfactory from a mathematical viewpoint [7], it looks in our opinion less coherent and its “physical” interpretation looks somewhat obscure.
