ABSTRACT—The purpose of this study was to elucidate the molecular mechanism for renal tetracycline transport by human organic anion transporters (hOATs) using proximal tubular cells stably expressing hOATs. The cells stably expressing hOAT1, hOAT2, hOAT3 and hOAT4 exhibited a higher amount of [³H]tetracycline uptake compared with mock cells. The apparent Kₘ values for hOAT2-, hOAT3- and hOAT4-mediated tetracycline uptakes were 439.9 ± 23.0, 566.2 ± 28.4 and 122.7 ± 16.0 µM, respectively. Tetracycline significantly inhibited the organic anion uptake by hOAT1, hOAT2 and hOAT4, but not hOAT3. In addition, oxytetracycline, minocycline and doxycycline inhibited the organic anion uptake by hOAT1, whereas oxytetracycline, minocycline but not doxycycline inhibited the organic anion uptake by hOAT2. In contrast, oxytetracycline, minocycline and doxycycline exhibited no significant inhibitory effects on the organic anion uptake by hOAT3 and hOAT4. HOAT1 and hOAT4 mediated the efflux of tetracycline, but hOAT2 and hOAT3 did not. These results suggest that hOAT1, hOAT2 and hOAT3 mediate the basolateral uptake and/or efflux of tetracycline, whereas hOAT4 is responsible for the reabsorption as well as the efflux of tetracycline in the apical side of the proximal tubule. These pharmacological characteristics of hOATs may be significantly related to events associated with the development of tetracycline-induced nephrotoxicity in the human kidney.

Materials and Methods

Materials

[3H]Tetracycline (333.6 GBq/mmol) was purchased from Sigma Chemical Co. (St. Louis, MO, USA). Fetal bovine serum (FBS), trypsin and genetin were obtained from Gibco/BRL (Gaithersburg, MD, USA), recombinant epidermal growth factor (EGF) from Wakanaga (Hirosima), insulin from Shimizu (Shizuoka), RITC 80-7 culture medium from Iwaki Co. (Tokyo) and TiX-50 from Promega (Madison, WI, USA).

Cell culture and establishment of S2; hOAT2 and S2; hOAT4

S2 cells, derived from transgenic mice harboring the temperature-sensitive simian virus 40 large T-antigen gene, were established as described previously (17). The establishment and characterization of S2; hOAT1 and S2; hOAT3 have been reported previously (18). The full-length cDNA of hOAT2 was isolated by screening human kidney cDNA library using rat OAT2 cDNA as the probe. The full-length cDNAs of hOAT2 and hOAT4 (8) were subcloned into pcDNA 3.1 (Invitrogen, San Diego, CA, USA), a mammalian expression vector. S2; hOAT2 and S2; hOAT4 were obtained by transfecting S2 cells with pcDNA3.1-hOAT2 or pcDNA3.1-hOAT4 coupled with pSV2neo, a neomycin resistance gene using a liposome (19). S2 cells transfected with pcDNA3.1 lacking an insert and pSV2neo were designated as S2 pcDNA 3.1 and used as a control (mock cells). These cells were grown in a humidified incubator at 33°C and 5% CO2, using RITC 80-7 medium (Iwaki Co.) that contained 5% of FBS, 10 μg/ml of transferrin, 0.08 U/ml of insulin, 10 ng/ml of recombinant EGF and 400 μg/ml of genetin (19). The cells were subcultured in a medium containing 0.05% trypsin-EDTA solution (137 mM NaCl, 5.4 mM KCl, 5.5 mM glucose, 4 mM NaHCO3, 0.5 mM EDTA and 5 mM HEPES; pH 7.2) and used for 25 – 35 passages. Clonal cells were isolated using a cloning cylinder and screened by determining the optimal substrate for each transporter; i.e., [14C]PAH for hOAT1 (5), [3H]PGF2α for hOAT2 and [3H]ES for hOAT3 and hOAT4 (8, 9). S2 hOAT2 and S2 hOAT4 exhibited a dose-and time-dependent increase in PGF2α and ES uptake activities, respectively. The S2 monolayer was determined to be leaky based on the results of a study wherein we estimated paracellular secretion from cells cultured on a permeable support, using D-[14C]manitol as an indicator. In addition, vertical sections of S2 hOAT2 and S2 hOAT4 stained with polyclonal antibodies against hOAT2 and hOAT4, respectively, showed that the subcellular localization of hOAT2 and hOAT4 proteins was mainly on the cell membrane (A. Enomoto et al., unpublished observation; E. Babu et al., unpublished observation). Both the basolateral and apical portions of the membrane showed positive staining. Therefore, the cells were cultured on a solid support for the following experiments.
**Uptake experiment**

Uptake experiments were performed as previously described (18, 19). The S₂ cells were seeded in 24-well tissue culture plates at a density of $1 \times 10^5$ cells/well. After the cells were cultured for two days, the cells were washed three times with Dulbecco’s modified phosphate-buffered saline (D-PBS) solution (137 mM NaCl, 3 mM KCl, 8 mM NaHPO₄, 1 mM KH₂PO₄, 1 mM CaCl₂ and 0.5 mM MgCl₂, pH 7.4) containing 5 mM D-glucose and then preincubated with the same solution at 37°C for 10 min in a water bath. The cells were then incubated in D-PBS containing 5 mM D-glucose with $[^3]$H)tetracycline at 37°C, as indicated in each experiment. The uptake was stopped by the addition of ice-cold D-PBS, and the cells were washed three times with the same solution. The cells in each well were lysed with 0.5 ml of 0.1 N sodium hydroxide and 2.5 ml of aquasol-2, and radioactivity was determined using a β-scintillation counter (LSC-3100; Aloka, Tokyo).

**Inhibition study**

To evaluate the inhibitory effects of tetracyclines on the organic anion transport by hOATs, S₂ hOAT1, S₂ hOAT2, S₂ hOAT3 and S₂ hOAT4 were incubated in solution containing either 5 μM $[^3]$H]PAH for 2 min (hOAT1), 50 nM $[^3]$H]PGF₂α for 30 s (hOAT2) or 50 nM $[^3]$H]ES for 2 min (hOAT3 and hOAT4) in the absence or presence of tetracyclines. Tetracycline, oxytetracycline, minocycline and doxycycline were dissolved in distilled H₂O and diluted with the incubation medium.

**Efflux study**

The efflux study was performed as previously described (19). S₂ hOAT1, S₂ hOAT2, S₂ hOAT3, S₂ hOAT4 and mock cells were seeded in 24-well tissue culture plates at a density of $1 \times 10^5$ cells/well. After the cells were cultured for two days, the cells were washed three times with D-PBS and then preincubated in the same solution at 37°C for 10 min in a water bath. Thereafter, the monolayers were incubated with 2 μM $[^3]$H)tetracycline at 37°C for 30 min, washed immediately three times with D-PBS and then incubated with 500 μl of D-PBS. After the incubation for the indicated periods of time, 50 μl of the supernatant was collected. After the incubation, the medium was aspirated immediately and the cell monolayers were

**Fig. 2.** Time course of tetracycline uptake by hOATs. S₂ hOAT1 (A), S₂ hOAT2 (B), S₂ hOAT3 (C), S₂ hOAT4 (D) and S₂ pcDNA 3.1 (mock cells) were incubated in solution containing 2 μM $[^3]$H)tetracycline for 1 min to 45 min at 37°C. The values of the mock cells were subtracted. Each value represents the mean ± S.E.M. of four determinations.
Fig. 3. Specificity of tetracycline uptake by hOATs. S2 hOAT1 (A), S2 hOAT2 (B), S2 hOAT3 (C), S2 hOAT4 (D) and S2 pcDNA 3.1 (mock cells) (E) were incubated in solution containing 2 μM $[^3H]$tetracycline and 2 μM $[^{14}C]$mannitol for 15 min at 37°C. Each value represents the mean ± S.E.M. of four determinations.

Fig. 4. Concentration dependence of tetracycline uptake by hOAT2 (A), hOAT3 (B) and hOAT4 (C) and its kinetic analysis. S2 hOAT2, S2 hOAT3, S2 hOAT4 and S2 pcDNA 3.1 (mock cells) were incubated in solution containing various concentrations of $[^3H]$tetracycline for 2 min at 37°C. The values of the mock cells were subtracted. The Eadie-Hofstee plots of the uptake of $[^3H]$tetracycline by hOAT2 (D), hOAT3 (E) and hOAT4 (F) were analyzed. Each value represents the mean ± S.E.M. of four determinations.
washed three times with the medium and solubilized in 0.5 ml of 0.1 N sodium hydroxide. The radioactivities within the supernatant and cell lysate were measured by counting the radioactivity. The rate of efflux at each time point was calculated by the following formula: (effluxed $[^3]H$tetacycline by transfectants – effluxed $[^3]H$tetacycline by mock) / ($[^3]H$tetacycline accumulated by transfectants at time 0 – $[^3]H$tetacycline accumulated by mock at time 0).

**Statistical analyses**

Data are expressed as the mean ± S.E.M. Statistical differences were determined by Student’s unpaired t-test. Differences were considered significant at $P<0.05$.

**RESULTS**

**Tetracycline uptake by hOATs**

We evaluated the time-dependent uptake of tetracycline by hOATs. As shown in Fig. 2, S$_2$ hOAT1 (A), S$_2$ hOAT2 (B), S$_2$ hOAT3 (C) and S$_2$ hOAT4 (D) were incubated in solution containing either 5 μM $[^{14}C]$PAH for 2 min (hOAT1), 5 nM $[^3]H$PGF$_{2α}$ for 30 s (hOAT2) or 50 nM $[^3]H$E2 for 2 min (hOAT3 and hOAT4) in the absence or presence of tetracycline, oxytetracycline, minocycline or doxycycline for 2 min at 37°C. Each value represents the mean ± S.E.M. of four determinations. *$P<0.05$, **$P<0.01$ and ***$P<0.001$ vs control.
(B), S₂ hOAT3 (C) and S₂ hOAT4 (D) exhibited higher amounts of tetracycline uptake than S₂ pcDNA 3.1. In order to confirm the specificity of tetracycline uptake mediated by hOATs, cells were incubated in a solution containing 2 μM [³H]tetracycline and 2 μM [¹⁴C]mannitol for 15 min. As shown in Fig. 3, tetracycline uptake values by these transfectants were higher than that by the mock cells, whereas mannitol uptake values were comparable among these cells.

The kinetics of tetracycline uptake was examined to evaluate the pharmacological characteristics of hOAT2, hOAT3 and hOAT4 on the tetracycline uptake. Since the amount of specific tetracycline uptakes in S₂ hOAT1 was small, kinetic analysis of the concentration dependence was not performed for hOAT1. The specific uptake of tetracycline by hOAT2, hOAT3 and hOAT4 revealed saturable kinetics (Fig. 4: A, B and C), and the Eadie-Hofstee plots gave a single straight line (Fig. 4: D, E and F). The estimated Kₘ values of tetracycline uptake by hOAT2, hOAT3 and hOAT4 were 439.9 ± 23.0 μM (N = 4), 566.2 ± 28.4 μM (N = 4) and 122.7 ± 16.0 μM (N = 4), respectively. The results suggest that hOAT1, hOAT2, hOAT3 and hOAT4 are responsible for the transport of tetracycline.

**Inhibitory effects of tetracyclines on the organic anion uptake by hOATs**

In order to elucidate whether hOATs interact with tetracyclines, we examined the effects of various tetracyclines on the organic anion uptake by hOAT1, hOAT2, hOAT3 and hOAT4. As shown in Fig. 5A, tetracycline, oxytetracycline, minocycline and doxycycline significantly inhibited the organic anion uptake by hOAT1 (N = 4, P < 0.001 and P < 0.01 vs control). As shown in Fig. 5B, tetracycline, oxytetracycline and minocycline (N = 4, P < 0.01 and P < 0.05 vs control), but not doxycycline, significantly inhibited the organic anion uptake by hOAT2. In contrast, none of the tetracyclines tested inhibited the hOAT3-mediated organic anion uptake (N = 4, N.S. vs control) (Fig. 5C). Figure 5D shows that tetracycline (N = 4, P < 0.01 vs control), but not oxytetracycline, minocycline and doxycycline, significantly inhibited the organic anion uptake by hOAT4.

**Efflux of tetracycline by hOATs**

In order to determine whether hOATs mediate the efflux of tetracycline, we compared the efflux of tetracycline by S₂ hOAT1, S₂ hOAT2, S₂ hOAT3 and S₂ hOAT4 with that by mock cells. As shown in Fig. 6, S₂ hOAT1 (A) and S₂ hOAT4 (B) exhibited a significant amount of tetracycline efflux, in which the amount of tetracycline efflux by mock cells was subtracted. In contrast, S₂ hOAT2 and S₂ hOAT3 did not mediate tetracycline efflux (data not shown).

**DISCUSSION**

hOAT1 and hOAT3 have been shown to mediate the transport of nonsteroidal anti-inflammatory drugs, antitumor drugs, histamine H₂-receptor antagonist, prostaglandins, diuretics, angiotensin-converting enzyme inhibitors and beta-lactam antibiotics (5, 9). Some differences in characteristics exist between hOAT1 and hOAT3, such as substrate specificity and localization: hOAT1 at the basolateral side of the S₂ segment of the proximal tubule (5) versus hOAT3 at the first, second and third segments (S₁, S₂ and S₃) of the proximal tubule (9). In addition, hOAT1, but not hOAT3, exhibits transport properties as an exchanger (5, 9). hOAT2, also identified to be localized to the basolateral side of the proximal tubule, mediated the transport of antivirals, including zidovudine and acyclovir, and sali-
cylate, but not \textit{para}-aminohippuric acid, estrone sulfate, methotrexate and ochratoxin A (Y. Kobayashi et al., unpublished observation). HOAT4 was isolated from human placenta (8) and found to localize to the apical side of the proximal tubule in the kidney. HOAT4 was shown to mediate the transport of various anionic drugs including \textit{para}-aminohippuric acid, estrone sulfate, methotrexate and ochratoxin A (ref. 8; E. Babu et al., unpublished observation).

In the current study, hOAT1, hOAT2, hOAT3 and hOAT4 were shown to mediate the uptake of tetracycline. In addition, tetracycline significantly inhibited the organic anion uptake by hOAT1, hOAT2 and hOAT4, which confirmed the interaction between tetracycline and hOAT1, hOAT2 or hOAT4. Thus, it was suggested that hOAT1, hOAT2 and hOAT3 mediate the uptake of tetracycline in the basolateral side of the proximal tubule, whereas hOAT4 mediated not only the reabsorption but also the efflux of tetracycline in the apical side of the proximal tubule. Renal clearance of tetracycline in normal subjects was reported to be 74 ml/min (20), whereas the creatinine clearance was 104 – 139 ml/min (21). Thus, it was suggested that urinaiy tetracycline is reabsorbed in tubules, and hOAT4 plays some roles in this reabsorption. Tetracycline exhibited no significant inhibitory effects on hOAT3-mediated organic anion uptake. The results were inconsistent with the tetracycline uptake activity shown in Figs. 2, 3 and 4. The reason for this discrepancy remains unknown and the further studies should be performed to clarify this.

The results of the inhibition experiments provide the possibility that oxytetracycline, minocycline and doxycycline are taken up via hOAT1 and hOAT2 on the basolateral side of the proximal tubule. In contrast, since oxytetracycline, minocycline and doxycycline exhibited no significant inhibitory effects on hOAT4-mediated organic anion uptake, it should be elucidated whether apical transporters mediating organic anion transport other than hOAT4, i.e., OAT-K1 (10), OAT-K2 (11), oatp1 (12), MRp2 (15) and NPT1 (16), interact with these tetracyclines. In addition to these specific pathways, since minocycline and doxycycline are lipophilic, these drugs are also transported via passive diffusion. In addition, the molecular background of these divergent inhibitory effects of tetracyclines on hOATs should be elucidated in terms of the structure-function relationship.

Tetracyclines have been shown to induce various forms of nephrotoxicity (1, 22). Outdated tetracycline products resulted in a Fanconi-like syndrome (renal tubular abnormality), with acidosis, nephrosis and aminoaciduria. Tetracyclines may also cause further increases in blood urea nitrogen and serum creatinine levels in patients with renal failure. These biochemical changes as well as tetracycline-induced azotemia have been attributed to the anti-anabolic effect of the drug. One possible explanation of how hOATs are associated with tetracycline-induced nephrotoxicity is that hOAT1, hOAT2 and hOAT3 mediate tetracycline uptake in the basolateral side, while hOAT4 mediates tetracycline reabsorption in the apical side, which may lead to the accumulation of tetracycline and the induction of its nephrotoxic effects. In contrast, toxicological implication of hOAT4-mediated tetracycline efflux remains unknown and further studies should be performed.

In conclusion, these results suggest that hOATs mediate the urinary excretion and the reabsorption of tetracycline in the proximal tubule. These transport characteristics may be associated with the induction of tetracycline-induced nephrotoxicity.
