ABSTRACT

We present two new planetary systems found around cool dwarf stars with data from the K2 mission. The first system was found in K2-239 (EPIC 248545986), characterized in this work as M3.0V and observed in the 14th campaign of K2. It consists of three Earth-size transiting planets with radii of 1.1, 1.0 and 1.1 R⊕, showing a compact configuration with orbital periods of 5.24, 7.78 and 10.1 days, close to 2:3:4 resonance. The second was found in K2-240 (EPIC 249801827), characterized in this work as M0.5V and observed in the 15th campaign. It consists of two transiting super-Earths with radii 2.0 and 1.8 R⊕ and orbital periods of 6.03 and 20.5 days. The equilibrium temperatures of the atmospheres of these planets are estimated to be in the range of 380-600 K and the amplitudes of signals in transmission spectroscopy are estimated at ~10 ppm.

Key words: planets and satellites: detection – techniques: photometric – techniques: spectroscopic – stars: low mass – stars: individual: K2-239, K2-240

1 INTRODUCTION

Low-mass stars are primary targets in the search for Earth-size planets and in the study of their properties. Low-mass stars (0.1 M☉ < M < 0.6 M☉) account for 70% of the stellar population in the Milky Way (Henry et al. 1994), meaning they have a hugely significant impact in the overall statistics of planets in the Galaxy. Exoplanets with close-in orbits tend to be terrestrial when the mass of the star decreases (Howard et al. 2012), with an average of ~0.5 Earth-size rocky planet with Porb < 50 days around each low-mass star (Dressing & Charbonneau 2015).

Transiting Earth-size planets induce deeper dimmings in the light-curve of low mass stars and stronger radial velocity signals than in more massive stars. Temperate planets orbit closer and have shorter orbital periods, so it is easier to detect planets in the habitable zone (orbital range in which a planet’s atmosphere can warm the surface to allow surface liquid water) (Anglada-Escudé et al. 2016; Gillon et al. 2017). Signals in transit transmission spectroscopy (Charbonneau et al. 2002) are also stronger for stars with a small radius, so planets orbiting near bright low-mass stars are also suitable for atmospheric characterization (Kreidberg et al. 2014).

Detecting transiting planetary systems is of great value in terms of estimating the mass and density of their planets measuring transit timing variations (Gillon et al. 2017), which are stronger for compact systems in resonances. These systems are also suitable for testing the formation scenarios from the study of resonances that could be the result of migrations (Papaloizou & Szuszkiewicz 2005).

Until now, the Kepler mission (Borucki et al. 2010) has

⁎ E-mail: fjcos@uniovi.es

© 2018 The Authors
been the most successful facility detecting exoplanets by the transit method. Since the beginning of 2014, Kepler has been on its second mission (K2) (Howell et al. 2014), monitoring different fields near the ecliptic plane for ~80 days. K2 has found many exoplanet candidates (Vanderburg et al. 2015; Crossfield et al. 2016; Diez Alonso et al. 2018; Hirano et al. 2018) in each observation campaign.

Campaign 14 was conducted between May 31st and August 19th 2017, centering on the Leo and Sextant area (central coordinates α=10:42:34, δ=+06:51:06). Campaign 15 ran between August 23rd and November 20th 2017, observing the area towards the constellation of Scorpius (central coordinates α=15:34:28, δ=−29:04:44).

In this study we present the detection of two planetary system during these campaigns. The first consists of three Earth-size transiting planets orbiting K2-239 (EPIC 248545986) (α=10:42:22.633, δ=+04:26:28.86), observed in long cadence mode during campaign 14. The second consists of two transiting super-Earths orbiting K2-240 (EPIC 249801827 (α=15:11:23.907, δ=−17:52:30.78), observed in long cadence mode during campaign 15.

2 SPECTROSCOPIC AND PHOTOMETRIC DATA

2.1 Stellar characterization: K2-239

On March 13th 2018 we obtained spectra of K2-239 with the OSIRIS camera-spectrograph (Cepa et al. 2000) of the 10.4 m Gran Telescopio Canarias (GTC), located at Observatorio Roque de los Muchachos in La Palma (Canary Islands, Spain). Three medium-resolution spectra (J/H/K ∼ 2500) in each of the BVRI bands were reduced in the standard manner, flux calibrated, telluric corrected, and finally combined into a single spectrum (see Fig. 1).

The spectrum was compared with SDSS/BOSS reference spectra of M-type stars from Kesseli et al. (2017). The comparison was made with the HAMMER code (Covey et al. 2007), obtaining the best fit for a M3V star with [Fe/H] ~ 0. The relative intensity of the NaI lines at 5890 and 8180 Å points to the possibility of the star being giant, while the relative depth of the strong molecular bands of TiO at 7000-7300 Å points to [Fe/H] ~ 0. Malonado et al. (2015), working with measurements of spectral index from HARPS spectra, conclude Teff ∼ 3450 ± 50 K for M3V stars, which is in agreement with our estimates of the stellar parameters. Figure 1 plots our comparison of the OSIRIS spectrum of K2-239 with reference spectra from M2.0V to M4.0V stars.

We computed the stellar parameters from J,H,V,K magnitudes listed in Table 1, applying the empirical relationships established by Mann et al. (2013, 2015) and Pecaut & Mamajek (2013), using the tabulated stellar parameters from Pecaut & Mamajek (2013) and the Mass - Luminosity relation for Main-sequence M dwarfs from Benedict et al. (2016). All the parameters are listed in Table 1.

Taking mV = 14.549 ± 0.040 (Table 1) and MV = 11.09 ± 0.10 from Pecaut & Mamajek (2013) tabulated parameters, we estimate a distance to K2-239 of 49 ± 3 pc.

We measured a radial velocity from the OSIRIS spectrum νr = −8.5 ± 1.5 kms⁻¹, which combined with the estimated distance and the proper motions μα = −41.0 ± 3.9 [mas/yr] and μδ = 10.5 ± 8.4 [mas/yr], results in the velocity components listed in Table 1. From the probability distributions of Reddy et al. (2006), we derive that K2-239 is a member of the Galactic thin disk.

2.2 Stellar characterization: K2-240

K2-240 has been observed by the Radial Velocity Experiment (RAVE) (Steinmetz et al. 2006). RAVE’s DR5 (Kunder et al. 2017) presents data from medium-resolution spectra (R ~ 7500) covering the Ca-triplet region (8410-8795 Å). From RAVE’s DR5 we find for K2-240 (RAVE J151123.9-175231) Teff = 3800 ± 87 K and log g = 4.50 ± 0.17, confirming that K2-240 is a cool dwarf star.

We repeated exactly the same analysis followed for K2-239 to derive the stellar parameters accurately, obtaining the parameters listed in Table 1. These parameters are consistent with K2-240 being a M0.5V star.

We also note that a very clear rotation signal is present in the light curve from K2. From a Lomb-Scargle (Scargle 1982) analysis we estimate Prot = 10.8 ± 0.1 d.

From RAVE’s radial velocity νr = 0.20 ± 1.56 kms⁻¹, our estimated distance of d = 70 ± 3 pc, and proper motions μα = −53.6 ± 1.5 [mas/yr] and μδ = −49.8 ± 1.0 [mas/yr], we compute velocity components listed in Table 1. From the probability distributions of Reddy et al. (2006), we derive that K2-240 is a member of the Galactic thin disk.

2.3 K2 photometric data

We followed the work of Vanderburg & Johnson (2014) to analyze the K2 corrected photometry of our target stars, detrending stellar variability with a spline fit and searching for periodic signals using the Box Least Squares (BLS) method (Kovács et al. 2002) on attained data. This analysis shows three transit signals with periods 5.240±0.001 (b), 7.775±0.001 (c) and 10.115±0.001 (d) days in K2-239 and two transit signals with periods 6.034±0.001 (b) and 20.523±0.001 (c) days in K2-240 (Fig. 2).
Two planetary systems with transiting Earth-size and super-Earth planets orbiting late-type dwarf stars

For each data point, Mandel & Agol summarizes all the parameters obtained for the planetary system. For the calculations, we set the values of $T_{\text{eff}}$, log $g$, and [Fe/H] listed in Table 1, and orbital periods listed above. We also worked with the assumption of eccentricity $e = 0$, valid for transiting planets in a multi-planetary system (Van Eylen & Albrecht 2015).

The planets in the K2-239 system have estimated radii 1.1 ± 0.1 $R_{\oplus}$ (b), 1.0 ± 0.1 $R_{\oplus}$ (c) and 1.1 ± 0.1 $R_{\oplus}$ (d), orbital periods of 5.242±0.001 days (b), 7.775±0.001 days (c) and 10.115±0.001 days (d), and semimajor axis 0.0441 ± 0.0008 AU (b), 0.0576 ± 0.0009 AU (c) and 0.0685 ± 0.0012 AU (d).

The planets in the K2-240 system have estimated radii 2.0$^{+0.1}_{-0.2}$ $R_{\oplus}$ (b) and 1.8$^{+0.3}_{-0.1}$ $R_{\oplus}$ (c), orbital periods of 6.034±0.001 days (b) and 20.523±0.001 days (c), and semimajor axis 0.0513 ± 0.0009 AU (b), 0.1159 ± 0.0020 AU (c). Table 2 summarizes all the parameters obtained for the planets.

We performed MCMC analysis on each phase-folded transit (Figs. 3 and 4) to estimate the planetary parameters, fitting models from Mandel & Agol (2002) with the Exofast package (Eastman et al. 2013). For each data point, the light curve was resampled every 10 times uniformly spaced over the 29.5-minute long cadence of K2 and averaged, following Kipping (2010). For the calculations we set the values of $T_{\text{eff}}$, log $g$, and [Fe/H] listed in Table 1, and orbital periods above.

Table 1. Stellar parameters for K2-239 and K2-240

| Parameter | K2-239     | K2-240     | Source   |
|-----------|------------|------------|----------|
| V [mag]   | 14.549 ± 0.040 | 13.392 ± 0.010 | (1)      |
| R [mag]   | 13.906 ± 0.020 | 12.804 ± 0.010 | (1)      |
| I [mag]   | 12.718 ± 0.030 | 11.994 ± 0.050 | (1)      |
| J [mag]   | 10.781 ± 0.026 | 10.394 ± 0.027 | (2)      |
| H [mag]   | 10.192 ± 0.021 | 9.745 ± 0.024 | (2)      |
| K [mag]   | 9.971 ± 0.021 | 9.560 ± 0.023 | (2)      |
| $T_{\text{eff}}$ [K] | 3420 ± 18 | 3810 ± 17 | (3)      |
| [Fe/H]    | −0.1 ± 0.1 | −0.1 ± 0.1 | (3)      |
| Radius $R_{\odot}$ | 0.36 ± 0.01 | 0.54 ± 0.01 | (3)      |
| Mass $M_{\odot}$ | 0.40 ± 0.01 | 0.58 ± 0.01 | (3)      |
| Luminosity $L_{\odot}$ | 0.016 ± 0.001 | 0.053 ± 0.002 | (3)      |
| log $g$ [cgs] | 4.9 ± 0.1 | 4.7 ± 0.1 | (3)      |
| $P_{\text{rot}}$ [d] | 10.8 ± 0.1 | 10.8 ± 0.1 | (3)      |
| Distance [pc] | 49 ± 3 | 70 ± 3 | (3)      |
| $\mu_{\alpha}$ [mas/yr] | −41.0 ± 3.9 | −53.6 ± 1.5 | (1)      |
| $\mu_{\delta}$ [mas/yr] | 10.5 ± 8.4 | −49.8 ± 1.0 | (1)      |
| $U$, $V$, $W$ [km/s] | −6.8, 4.2, −10.2 | −5.4, −23.6, −1.7 | (3)      |

Figure 3. Phase-folded light curves corresponding to planets b (top), c (middle), and d (bottom) in the K2-239 system. Solid curves represent best model fits obtained by MCMC.

2.4 False positives analysis

We acquired images of K2-239 with the OSIRIS cameraspectrograph on March 13$^{th}$ 2018. Night conditions were rather good, and data were collected under photometric conditions, a dark moon, and with an average seeing of 0.7 arc seconds. For broadband imaging, a series of 10 x 1 sec in Sloan i filter was obtained. Bias correction, flat fielding and bad pixel masking were done using standard procedures, and the images were finally aligned (see Fig. 5, top panel). Analyses of final image exclude companions at 0.6 arc seconds with $\delta$mag < 5.0 and at 3 arc second with $\delta$mag < 10.

In the same way, images from POSS-I (Minkowski & Abell 1963) (year 1953) and 2MASS (Cutri et al. 2003) (year 1998, see Fig. 5, top panel) do not show background sources at the current star position.
At ExoFOP–K2, an AO image of K2-240 is available, acquired with the NIRC2 instrument at the 10 m Keck 2 telescope (Maunakea, Hawaii). The image excludes companions at 0.2 arc seconds with δmag < 5.0 and at 1 arc second with δmag < 8.3 (Fig. 5, bottom panel).

Non-detection of blended objects in these images and the extremely low probability of multiple false positives as shown by Lissauer et al. (2011) confirm the planetary origin of transit signals in K2-239 and K2-240.

3 DISCUSSION AND CONCLUSIONS

Assuming the planet radii listed in Table 2, and the mean density for planets satisfying $R_p \leq 1.5 R_\oplus$ from Weiss & Marcy (2014), we obtain $M_p = 1.4 \pm 0.4 M_\oplus$, $M_c = 0.9 \pm 0.3 M_\oplus$, $M_d = 1.3 \pm 0.4 M_\oplus$ for planets b, c, and d, respectively in the K2-239 system. Adopting $M_p \ll M_\star$, circular orbits and sin i ≈ 1, we computed induced semi-amplitudes in stellar velocity variations of 0.9 ms$^{-1}$ for planet b, 0.5 ms$^{-1}$ for planet c and 0.7 ms$^{-1}$ for planet d, well-suited for radial velocity monitoring with ultra-stable spectrographs such as ESPRESSO (Pepe et al. 2014; González Hernández et al. 2017) at the VLT.

The amplitude of the signal in transit transmission spectroscopy can be estimated as $R_p h_{\text{eff}}$ (Gillon et al. 2016) with $h_{\text{eff}}$ the effective atmospheric height. $h_{\text{eff}}$ is related to the atmospheric scale height $H = K T / \mu g$ (K Boltzmann’s constant, T atmospheric temperature, $\mu$ atmospheric mean molecular mass, g surface gravity). Assuming $h_{\text{eff}} = 7 H$ (Miller-Ricci & Fortney 2010) for a transparent volatile dominated atmosphere ($\mu = 20$) with 0.3 Bond albedo, we found amplitudes in transit transmission spectroscopy of 1.2 $10^{-5}$ (b), 1.1 $10^{-5}$ (c) and 10$^{-5}$ (d).

We used the Mercury package (Chambers 1999) to simulate and test the evolution and stability of the system for 10$^6$ years. We simulated using Bulirsch – Stoer integrator, adopting circular orbits and masses from the mass-radius relation. We do not find significant changes in the eccentricity or in the inclination of the orbits, showing a dynamically stable system.

To estimate the masses for the planets of the K2-240 system we used the mass-radius relation from Weiss & Marcy (2014) for planets satisfying $1.5 \leq R_p/R_\oplus \leq 4$, obtaining $M_p = 5.0^{+0.5}_{-0.2} M_\oplus$, $M_c = 4.6^{+0.7}_{-0.3} M_\oplus$. Under the assumption of $M_p \ll M_\star$, circular orbits and sin i ≈ 1, we computed induced semi-amplitudes in stellar velocity variations of 2.5 ms$^{-1}$ for planet b and 1.5 ms$^{-1}$ for planet c. With the same assumptions as in the previous section, we estimate amplitudes in transit transmission spectroscopy of 1.2 $10^{-5}$ (b) and 6.6 $10^{-6}$ (c).

We also tested the stability of K2-240 system with the Mercury package as described in the previous section. Again our simulations point towards a dynamically stable system.

The planetary systems presented in this work, with equilibrium temperatures estimated in the range 380-600 K, are suitable targets for incoming facilities; Plato, monitoring in shorter cadence mode, could reveal transit timing variations that allow accurate planetary masses to be estimated. The James Webb Telescope could find signs of planetary atmospheres. Ultra-stable spectrographs such as ESPRESSO at VLT, could also carry out radial velocity follow-up, so these are promising targets to improve our understanding of compact Earth-sized planetary systems (K2-239) and super-
