ABSTRACT

In natural convection, the fluid motion occurs by natural means such as buoyancy. Heat transfer by natural convection happens in many physical problems and engineering applications such as geothermal systems, heat exchangers, petroleum reservoirs and nuclear waste repositories. These problems and phenomena are modeled by ordinary or partial differential equations. In most cases, experimental solutions cannot be applied to these problems, so these equations should be solved using special techniques. In this paper, natural convection of a non-Newtonian fluid flow between two vertical flat plates is investigated analytically and numerically. Collocation Method (CM) and fourth-order Runge-Kutta numerical method (NUM) are used to solve the present problem. These methods are powerful and convenient algorithms in finding the solutions for the equations. While these are capable of reducing the size of calculations. In order to compare with exact solution, velocity and temperature profiles are shown graphically. The obtained results are valid with significant accuracy.

INTRODUCTION

Natural convection is a very important mechanism that is operative in a variety of environments from cooling electronic circuit boards in computers to causing large scale circulation in the atmosphere as well as in lakes and oceans that influences the weather. It is caused by the action of density gradients in conjunction with a gravitational field. Natural convection has attracted a great deal of attention from researchers because of its presence both in nature and engineering applications. In nature, convection cells formed from air rising above sunlight-warmed land or water are a major feature of all weather systems. In engineering applications, convection is commonly visualized in the formation of micro-structures during the cooling of molten metals, and fluid flows around shrouded heat-dissipation fins, and solar ponds. A very common industrial application of natural convection is free air cooling without the aid of fans: this can happen on small scales (computer chips) to large scale process equipment. Also heat transfer by natural convection occurs in many physical problems and engineering applications such as geothermal systems, heat exchangers, chemical catalytic reactors, fiber and granular insulation, packed beds, petroleum reservoirs and nuclear waste repositories. In view of its importance, the flow of Newtonian and non-Newtonian fluids through two infinite parallel vertical plates has been investigated by numerous authors. In this system heat is transferred from a vertical plate to a fluid moving parallel to it by natural convection.

Keywords: Natural convection; Non-Newtonian fluid; Partial differential equation; Collocation Method (CM); Numerical Method (NUM)
This will occur in any system wherein the density of the moving fluid varies with position. These phenomena will only be of significance when the moving fluid is minimally affected by forced convection [1]. The natural convection problem between vertical flat plates for a certain class of non-Newtonian fluids has been carried out by Bruce and Na [2]. Also other laminar natural convection problems involving heat transfer have been studied in [3]. However, Rajagopal presented a complete thermodynamic analysis of the constitutive functions [4]. These scientific problems and phenomena are modeled by ordinary or partial differential equations. In recent years, much attention has been devoted to the newly developed methods to construct an analytic solution of these equations; such as the perturbation method [5], variational techniques [6], Collocation Method (CM) and fourth-order Runge-Kutta numerical method (NUM) [7-15]. These methods have been used by some authors in wide variety of scientific and engineering applications to solve different types of governing differential equations: linear and nonlinear, homogeneous and non-homogeneous, and coupled and decoupled as well. Several researchers studied various problems by this accurate method [16-22]. These methods offer highly accurate successive approximations of the solution. Etbaieitabari and Domairy have studied analytically with Reconstruction of Variational Iteration Method (RVIM) scheme on present problem and their results had very good agreement with the older researches [23]. Therefore, Collocation Method was used to find efficient, reliable and precise polynomial solutions. Thus in this work we examine the natural convection of a non-Newtonian fluid, namely the Rivlin-Ericksen fluid of grade three, between two infinite parallel vertical flat plates to obtain its solution using CM and NUM.

**Description of the problem**

A schematic of the problem is shown in figure 1. It consists of two flat plates that can be positioned vertically. A non-Newtonian fluid is in two flat plates a distance 2b apart. The walls at $x=+b$ and $x=-b$ are held at constant temperatures $\phi_2$ and $\phi_1$ respectively, where $\phi_1>\phi_2$. This difference in temperature causes the fluid near the wall at $x=-b$ to rise and the fluid near the wall at $x=+b$ to fall. Rajagopal [4] has demonstrated that by using the similarity variables:

$$ U = \frac{u}{U_0}, \xi = \frac{x}{b}, \phi = \frac{T-T_m}{T_1-T_2} \tag{1} $$

The Navier-Stokes and Energy equations can be reduced to the following pair of ordinary differential equations [5]:

$$ \frac{d^2U}{d\xi^2} + 6\delta\left(\frac{dU}{d\xi}\right)^2 \frac{d^2U}{d\xi^2} + \phi = 0 \tag{2} $$

$$ \frac{d^2\phi}{d\xi^2} + E.Pr\left(\frac{dU}{d\xi}\right)^2 \frac{d^2U}{d\xi^2} + 2\delta E.Pr\left(\frac{dU}{d\xi}\right)^4 = 0 \tag{3} $$

$$ E = \frac{U_0^2}{c(\phi_1-\phi_2)}, Pr = \frac{\mu c}{k}, \delta = \frac{6\beta^2U_0^2}{\mu b^2} \tag{4} $$

Where $c$ is the specific heat of the fluid. The appropriate boundary conditions are:

$$ U = 0, \phi = +\frac{1}{2} \text{ at } \xi = -1 \tag{5} $$

$$ U = 0, \phi = -\frac{1}{2} \text{ at } \xi = +1 \tag{6} $$
After that, we solve the system of Eqs. (2) and (3) by using the CM and NUM. The equations are coupled and highly non-linear.

**MATHEMATICAL METHODS**

Before presenting the results, it is necessary to provide some background knowledge about the mathematical methods employed. Therefore, in this section, some basic relationships and theories concerning Collocation method (CM) and fourth order Runge-Kutta Numerical Method are presented.

There are some simple and accurate approximation techniques for solving differential equations called the Weighted Residuals Methods (WRMs). Collocation (CM), Galerkin (GM) and Least Square (LSM) are examples of the WRMs. Collocation Method (CM) were firstly introduced by Ozisik [24] for solving differential equations in heat transfer problems. Stern and Rasmussen [25] used collocation method for solving a third order linear differential equation. Vaferi et al. [26], studied the feasibility of applying of Orthogonal Collocation method to solve diffusivity equation in the radial transient flow system.

Many advantages of CM compared to other analytical make it more valuable and motivate researchers to use it for solving problems. Some of these advantages are listed below [14].

a) WRMs solve the equations directly and no simplifications are needed.

b) They do not need any perturbation, linearization or small parameter versus Homotopy Perturbation Method (HPM) and Parameter Perturbation Method (PPM).

c) They are simple and powerful compared to numerical methods and achieve final results faster than numerical procedures while their results are acceptable and have excellent agreement with numerical outcomes, furthermore their accuracy can be increased by increasing the statements of the trial functions.

d) They don’t need to determine the auxiliary parameter and auxiliary function versus Homotopy Analysis Method (HAM).

**Collocation Method (CM)**

For conception of the main idea of this method, suppose a differential operator \( D \) is acted on a function \( V \) to produce a function \( p \):

\[
D(V(X)) = p
\]  

(7)

We wish to approximate \( V \) by a function \( \tilde{V} \), which is a linear combination of basic s chosen from a linearly independent set. That is,

\[
V \approx \tilde{V} = \sum_{i=1}^{n} c_i \tau_i
\]  

(8)
Now, when substituted into the differential operator, $D,$ the result of the operations is not $p(X).$ Hence an error or residual will exist:

$$e(X) = R(X) = D(\hat{V}(X)) - p(X) \neq 0$$  \hspace{1cm} (9)

The notion in the Collocation is to force the residual to zero in some average sense over the domain. That is,

$$\int R(X)W_i(X) dX = 0$$  \hspace{1cm} (10)

where the number of weight functions $W_i$ is exactly equal the number of unknown constants $c_i$ in $\hat{v}.$ The result is a set of $n$ algebraic equations for the unknown constants $c_i.$ The value of $n$ has been guessed. For collocation method, the weighting functions are taken from the family of Dirac $\delta'$ functions in the domain. That is $W_i(X) = (X-X_i).$

The Dirac $\delta'$ function has the property of

$$\delta'(X-X_i) = \begin{cases} 1 & \text{if } X = X_i \\ 0 & \text{otherwise} \end{cases} \hspace{1cm} (11)$$

And residual function in Eq. (9) must be forced to be zero at specific points.

**Fourth order Runge-Kutta Method (NUM)**

It is obvious that the type of the current problem is boundary value problem (BVP) and the appropriate method needs to be chosen. The available sub-methods in the Maple 17.0 are a combination of the base schemes; trapezoid or midpoint method. There are two major considerations when choosing a method for a problem. The trapezoid method is generally efficient for typical problems, but the midpoint method is so capable of handling harmless end-point singularities that the trapezoid method cannot. The midpoint method, also known as the fourth-order Runge-Kutta-Fehlberg method, improves the Euler method by adding a midpoint in the step which increases the accuracy by one order. Thus, the midpoint method is used as a suitable numerical technique in present study [9].

**RESULTS AND DISCUSSION**

The applicability of the presented methods for the nonlinear equation of natural convection will be illustrated in the following section. In order to measure the accuracy of the results, NUM has been used here for the derived nonlinear ODE, given in Eqs. (2),(3). A Maple code was used to find the numerical solution of the present boundary value problem (BVP).

**Approximate solution with CM**

In present study, the fluid is considered non-Newtonian fluid and governing equations for investigation of temperature and velocity profiles of natural convection of non-Newtonian fluid between two parallel plates are solved by CM and NUM. For solving Eqs. (2) and (3) by WRMs, because trial function must satisfy the boundary condition in Eq. (5), so each statement in $\varphi(\xi)$ and $U(\xi)$ should contain $t$ to satisfy boundary condition in $\xi=+1$ and $\xi=-1.$ In this study, one statement is considered for velocity profile and one statement is considered for temperature profile and as explained in above WRMs advantages, accuracy of results can be increased by increasing the number of statements. Which satisfy the boundary condition in Eq. (5) and by setting it into Eqs. (2) and (3), residual functions, $R(c,\xi),$ will be found. On the other hand, the residual functions must be close to zero.
In this work, approximate polynomials for \( \phi(\xi) \) and \( U(\xi) \) are as follows:

\[
\phi(\xi) = -\frac{1}{2} \xi + c_1 (\xi^2 - 1) + c_2 (\xi - \xi^3) + c_3 (\xi - \xi^5) + c_4 (\xi - \xi^7)
\]

(12)

\[
U(\xi) = c_2 (\xi^2 - 1) + c_6 (\xi - \xi^3) + c_7 (\xi - \xi^5) + c_8 (\xi - \xi^7)
\]

(13)

For example, \( U(\xi) \) and \( \phi(\xi) \) by using Collocation Method with \( Pr=E=1 \) are as follows:

\[
U(\xi) = 0.0009514584443 - 0.08223709774\xi - 0.009514584443\xi^2 + 0.0770440732\xi^3 + 0.01098073994\xi^4 - 0.00578771252\xi^5 - 0.0009514584443\xi^6 + 0.0770440732\xi^7
\]

(14)

\[
\phi(\xi) = 0.00213661471 - 0.4965099425\xi - 0.00213661471\xi^2 + 0.04259875609\xi^3 + 0.06278384738\xi^4 - 0.02367514885\xi^5
\]

(15)

The results of the different methods of CM and NUM are compared in figures 2 and 3. Figures 2 shows the non-dimensional velocity \( \phi(\xi) \), while figure 3 shows the comparison of the non-dimensional velocity \( U(\xi) \) of CM and the numerical method (NUM) for known values of the parameters \( E=1 \) and \( Pr=1 \). Figures 4 and 5 illustrate effect of \( \delta \) on the non-dimensional temperature \( \phi(\xi) \) and velocity \( U(\xi) \) as well. Figure 5 indicates that by increasing \( \delta \) the amount of temperature increases for positive region and the same treatment is obvious for the minus region. And also as it is obvious in figures 4, the velocity for positive values of \( x \) increases by increasing \( \delta \). But there is an opposite manner in the minus region. Figures 6 and 7 show the result of \( \phi(\xi) \) and \( U(\xi) \) for various Prandtl number \( Pr \) when \( \delta=1 \) and \( E=1 \). According to figures 6 and 7 by increasing \( Pr \), the non-dimensional velocity \( U(\xi) \) and temperature \( \phi(\xi) \) increased. Also the same result is indicated increasing \( E \) in figures 8 and 9. According to tables 1 and 2 these approximate analytical solutions are in excellent agreement with the corresponding numerical solutions. In these tables different iterations of CM are tabulated to show the power of this method in finding an accurate approximation. It is obvious in tables 3 and 4 that show the errors.

CONCLUSIONS

In this paper, natural convection of a non-Newtonian fluid flow between two vertical flat plates is investigated analytically and numerically. Collocation Method (CM) and fourth-order Runge-Kutta numerical method (NUM) are used to solve the present problem. The proposed method overcame on nonlinearity without using restrictive assumptions or linearization. The following main points can be concluded from the present study.

• The results of CM are in excellent agreement with numerical ones. Also this method is simple, powerful and efficient techniques for finding analytical solutions in science and engineering non-linear differential equations which reduces the size of calculations.

• The figures bring out clearly the effect of $\delta$ on the non-dimensional temperature $\phi(\xi)$ and velocity $U(\xi)$ as well. While $\delta$ increases the amount of temperature increases at positive region and decreases at minus region of $x$.

• by increasing $Pr$ the non-dimensional velocity $U(\xi)$ and temperature $\phi(\xi)$ increased respectively and by increasing $E$ treatment of the non-dimensional velocity $U(\xi)$ and temperature $\phi(\xi)$ are additive.
